United States Patent	12394920
Kind Code	B2
Date of Patent	August 19, 2025
Inventor(s)	Fabozzi; Richard Benjamin et al.

Screwless connection terminals with wire manager

Abstract

Electrical wiring devices that incorporate clamp-type wire terminal connections are described. The electrical wiring devices include for example, single and duplex blade-type electrical receptacles, blade-type locking electrical receptacles, single or multi-pole electrical switches, combination switches and blade-type receptacles, blade-type plugs for electrical cords and blade-type connectors for electrical cords. The electrical wiring devices include a plurality of contact assemblies. Each contact assembly includes a wire terminal having a wire manager and a plunger.

Background/Summary

CROSS REFERENCE TO RELATED APPLICATIONS (1) The present disclosure is based on and claims benefit from U.S. Provisional Patent Application No. 63/248,609 filed on Sep. 27, 2021 entitled “Screwless Connection Terminals With Wire Manager” the contents of which are incorporated herein in their entirety by reference.

BACKGROUND
Field
(1) The present disclosure relates generally to connection terminals for electrical wiring devices and more particularly to screwless connection terminals for use in receptacles, plug assemblies, plug connectors, switches, and other electrical wiring devices.
Description of the Related Art
(2) Present electrical wire terminations in many electrical wiring devices are either direct pressure type terminations or screw and clamp type terminations. In direct pressure type terminations, a terminal screw is tightened directly against an electrical wire to press the wire against a fixed plate. In screw and clamp type terminations, a wire is inserted between a fixed plate and a movable plate, and a terminal screw is tightened so that the wire is clamped between the plates. With direct pressure type terminations, stranded or solid wires if incorrectly installed can be cut or nicked. Cut or nicked wires can result in poor electrical connections increasing the resistance in the connections which can cause overheating. In addition, with stranded wires, both direct pressure type terminations and screw and clamp type terminations may be susceptible to strand relaxation. Strand relaxation is a result of copper wire heating and cooling under the stress of the termination, either direct pressure type or screw and clamp type causing the electrical connection between the stranded wire and the termination to loosen increasing the resistance in the connections which can cause

overheating. To alleviate strand relaxation concerns, installers typically re-torque terminal screws after some duration of time after original installation increasing costs to consumers.

SUMMARY

(3) The present disclosure provides embodiments of various electrical wiring devices, including receptacles, power cord plugs and connectors, and switches. In an exemplary embodiment, a blade-type electrical receptacle includes a housing and a plurality of contact assemblies. The housing has a main body with a plurality of cavities, a front cover and a rear cover. The front cover is removably secured to a first side of the main body and includes a plurality of blade receiving slots. The rear cover is removably secured to a second side of the main body and includes a plurality of wire receiving apertures and a plurality of plunger openings.

(4) In one exemplary embodiment, one of the plurality of contact assemblies is positioned at least partially within one of the plurality of cavities and is accessible from one of the plurality of wire receiving apertures, from one of the plurality of plunger openings in the rear cover and is accessible from one of the plurality of blade receiving slots in the front cover. Each of the plurality of the contact assemblies includes a contact member, a wire terminal and a plunger. In an exemplary embodiment, the contact member has a contact body and at least two contact fingers extending from the contact body. The at least two contact fingers are aligned with one of the plurality of blade receiving slots in the front cover. The wire terminal forms an electrically conductive path with the contact member and includes a contact arm secured to the contact body, a clamp brace secured to the contact arm, a clamp spring secured to the clamp brace and a wire manager. The clamp spring is movable relative to the clamp brace between a closed position where a wire can be clamped between the clamp spring and the clamp brace and an open position where a wire can be inserted through one of the plurality of wire receiving apertures in the rear cover and between the clamp spring and the clamp brace. The wire manager is positioned on the clamp brace in close proximity to where the wire can be clamped between the clamp spring and the clamp brace. The plunger is positioned within one of the plurality of cavities and extends at least partially through one of the plurality of plunger openings in the rear cover. The plunger is interactive with the clamp spring such that movement of the plunger in a first direction relative to the clamp brace causes the plunger to apply a mechanical load to the clamp spring to cause the clamp spring to move from the closed position to the open position, and movement of the plunger in a second direction relative to the clamp brace removes the mechanical load from the clamp spring so that to the clamp spring is biased from the open position to the closed position.

(5) The present disclosure also provides embodiments of blade type electrical power cord connectors. In an exemplary embodiment, a blade-type electrical power cord connector includes a housing and a plurality of contact assemblies. The housing includes a main body, a cover and a retainer. The main body has a plurality of cavities and a plurality of blade receiving slots. The cover is removably secured to the main body and has a cable receiving aperture. The retainer is removably secured to the main body between the main body and the cover and has a plurality of wire receiving apertures and a plurality of plunger openings.

(6) In one exemplary embodiment, one of the plurality of contact assemblies is positioned at least partially within one of the plurality of a cavities and is accessible from one of the plurality of wire receiving apertures, from one of the plurality of plunger openings in the retainer and is accessible from one of the plurality of blade receiving slots in the main body. Each of the plurality of the contact assemblies includes a contact member, a wire terminal and a plunger. In an exemplary embodiment, the contact member has a contact body and at least two contact fingers extending from the contact body. The at least two contact fingers are aligned with one of the plurality of blade receiving slots in the main body of the housing. The wire terminal forms an electrically conductive path with the contact member and includes a clamp brace secured to the contact body, a clamp spring secured to the clamp brace and a wire manager. The clamp spring is movable relative to the clamp brace between a closed position where a wire can be clamped between the clamp spring and

the clamp brace and an open position where a wire can be inserted through one of the plurality of wire receiving apertures in the retainer and between the clamp spring and the clamp brace. The wire manager is positioned on the clamp brace in close proximity to where the wire can be clamped between the clamp spring and the clamp brace. The plunger is positioned within one of the plurality of cavities and extends at least partially through one of the plurality of plunger openings in the retainer. The plunger is interactive with the clamp spring such that movement of the plunger in a first direction relative to the clamp brace causes the plunger to apply a mechanical load to the clamp spring to cause the clamp spring to move from the closed position to the open position, and movement of the plunger in a second direction relative to the clamp brace removes the mechanical load from the clamp spring so that to the clamp spring is biased from the open position to the closed position.

(7) The present disclosure also provides embodiments of blade type electrical power cord plugs. In an exemplary embodiment, a blade-type electrical power cord plug includes a housing and a plurality of contact assemblies. The housing includes a main body, a bottom cover, a top cover and a retainer. The main body has a plurality of cavities. The bottom cover is removably secured to a first side of the main body and has a plurality of blade receiving slots. The top cover is removably secured to a second side of the main body and has a cable receiving aperture. The retainer is removably secured to the second side of the main body between the main body and the top cover and has a plurality of wire receiving apertures and a plurality of plunger openings.

(8) In one exemplary embodiment, one of the plurality of contact assemblies is positioned at least partially within one of the plurality of a cavities and is accessible from one of the plurality of wire receiving apertures, from one of the plurality of plunger openings in the retainer and is accessible from one of the plurality of blade receiving slots in the bottom cover. In an exemplary embodiment, the each of the plurality of the contact assemblies includes a contact member, a wire terminal and a plunger. The contact member has a contact body and a contact blade extending from the contact body. The contact blade is aligned with one of the plurality of blade receiving slots in the bottom cover such that the blade can pass through the blade receiving slot and extend from the housing. The wire terminal forms an electrically conductive path with the contact member and includes a clamp brace secured to the contact body, a clamp spring secured to the clamp brace and a wire manager. The clamp spring is movable relative to the clamp brace between a closed position where a wire can be clamped between the clamp spring and the clamp brace and an open position where a wire can be inserted through one of the plurality of wire receiving apertures in the retainer and between the clamp spring and the clamp brace. The wire manager is positioned on the clamp brace in close proximity to where the wire can be clamped between the clamp spring and the clamp brace. The plunger is positioned within one of the plurality of cavities and extends at least partially through one of the plurality of plunger openings in the retainer. The plunger is interactive with the clamp spring such that movement of the plunger in a first direction relative to the clamp brace causes the plunger to apply a mechanical load to the clamp spring to cause the clamp spring to move from the closed position to the open position, and movement of the plunger in a second direction relative to the clamp brace removes the mechanical load from the clamp spring so that to the clamp spring is biased from the open position to the closed position.

(9) The present disclosure also provides embodiments of electrical wiring device for installation into an electrical box. In an exemplary embodiment, the electrical wiring device includes a housing and a plurality of contact assemblies. The housing includes a main body portion having a plurality of cavities, a front cover portion removably secured to a first side of the main body portion, and a rear cover portion removably secured to a second side of the main body portion and having a plurality of wire receiving apertures and a plurality of plunger openings. In this embodiment, one of the plurality of contact assemblies is positioned at least partially within one of the plurality of a cavities and is accessible from one of the plurality of wire receiving apertures and one of the plurality of plunger openings in the rear cover portion. Each of the plurality of the contact

assemblies includes a wire terminal and a plunger. The wire terminal includes a clamp brace secured to a clamp spring and a wire manager. The clamp spring is movable relative to the clamp brace between a closed position where a wire can be clamped between the clamp spring and the clamp brace, and an open position where a wire can be inserted through one of the plurality of wire receiving apertures in the rear cover and between the clamp spring and the clamp brace. The wire manager is positioned on the clamp brace in close proximity to where the wire can be clamped between the clamp spring and the clamp brace. The plunger is positioned within one of the plurality of cavities and extends at least partially through one of the plurality of plunger openings in the rear cover. The plunger is interactive with the clamp spring such that movement of the plunger in a first direction relative to the clamp brace causes the plunger to apply a mechanical load to the clamp spring to cause the clamp spring to move from the closed position to the open position and movement of the plunger in a second direction relative to the clamp brace removes the mechanical load from the clamp spring so that to the clamp spring is biased from the open position to the closed position.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

(1) A more complete appreciation of the present disclosure and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings, wherein:

(2) FIG. **1** is a top perspective view of an exemplary embodiment of an electrical receptacle having screwless connection terminals according to the present disclosure;

(3) FIG. **2** is a bottom perspective view of the receptacle of FIG. **1**;

(4) FIG. **3** is a bottom plan view of the receptacle of FIG. **1**;

(5) FIG. **4** is a cross sectional view of the receptacle of FIG. **3** taken along line **4**-**4**;

(6) FIG. **5** is a cross sectional view of the receptacle of FIG. **3** taken along line **5**-**5**;

(7) FIG. **6** is a top perspective view of a rear cover of the receptacle housing of FIG. **1** with three contact assemblies resting on the rear cover;

(8) FIG. **7** is a bottom perspective view of a housing of the receptacle of FIG. **1** having three cavities each housing a contact assembly;

(9) FIG. **8** is a top perspective view of an exemplary embodiment of a screwless connection terminal for the receptacle of FIG. **1** in a closed position;

(10) FIG. **8**A is a perspective view of another exemplary embodiment of a screwless connection terminal for the receptacle of FIG. **1**, illustrating a wire manager secured to a clamp brace of a wire terminal;

(11) FIG. **8**B is a bottom perspective view of the screwless connection terminal of FIG. **8**A, illustrating the wire manager secured to the clamp brace;

(12) FIG. **9** is a top perspective view of the screwless connection terminal of FIG. **8** in an open position;

(13) FIG. **9**A is a top perspective view of the screwless connection terminal of FIG. **8**A in an open position and illustrating a stranded wire ready for insertion into the screwless connection terminal;

(14) FIG. **9**B is a perspective view of the screwless connection terminal of FIG. **9**A with the stranded wire inserted into the screwless connection terminal and the stranded wire resting in the wire manager;

(15) FIG. **9**C is a bottom perspective view of the screwless connection terminal of FIG. **9**B, illustrating the stranded wire resting in the wire manager;

(16) FIG. **9**D is an enlarged perspective view of a portion of the screwless connection terminal of

FIG. **9**C taken from detail **9**D, illustrating the stranded wire resting in the wire manager;
(17) FIG. **10** is a side elevation view of an exemplary embodiment of an electrical power cord connector having the screwless connection terminals according to the present disclosure;
(18) FIG. **11** is a bottom plan view of the cord connector of FIG. **10**;
(19) FIG. **12** is a side perspective view with parts separated of the cord connector of FIG. **10**;
(20) FIG. **13** is a top perspective view of a portion of the cord connector of FIG. **12**, illustrating a plurality of contact assemblies within a housing of the cord connector;
(21) FIG. **14** is a top perspective view of the portion of the cord connector of FIG. **12** with a retainer secured to a main body of the housing;
(22) FIG. **15** is a top perspective view of an exemplary embodiment of a screwless connection terminal for the cord connector of FIG. **10** in a closed position;
(23) FIG. **15**A is a perspective view of another exemplary embodiment of a screwless connection terminal for the receptacle of FIG. **10**, illustrating a wire manager secured to a clamp brace of a wire terminal;
(24) FIG. **15**B is a bottom perspective view of the screwless connection terminal of FIG. **15**A, illustrating the wire manager secured to the clamp brace;
(25) FIG. **16** is a top perspective view of the screwless connection terminal of FIG. **15** in an open position;
(26) FIG. **16**A is a top perspective view of the screwless connection terminal of FIG. **15**A in an open position and illustrating a stranded wire ready for insertion into the screwless connection terminal;
(27) FIG. **16**B is a perspective view of the screwless connection terminal of FIG. **16**A with the stranded wire inserted into the screwless connection terminal and the stranded wire resting in the wire manager;
(28) FIG. **16**C is a bottom perspective view of the screwless connection terminal of FIG. **16**B, illustrating the screwless connection terminal in the closed position and the stranded wire resting in the wire manager;
(29) FIG. **16**D is an enlarged perspective view of a portion of the screwless connection terminal of FIG. **16**C taken from detail **16**D, illustrating the stranded wire resting in the wire manager;
(30) FIG. **17** is a side elevation view of an exemplary embodiment of an electrical power cord plug having the screwless connection terminals according to the present disclosure;
(31) FIG. **18** is a side perspective view with parts separated of the cord plug of FIG. **17**;
(32) FIG. **19** is a top perspective view of a portion of the cord plug of FIG. **18**, illustrating a plurality of contact assemblies in a main body of a housing of the cord plug;
(33) FIG. **20** is a top perspective view of the portion of the cord plug of FIG. **18** with a retainer secured to the main body of the cord plug housing;
(34) FIG. **21** is a top perspective view of an exemplary embodiment of a screwless connection terminal for the cord plug of FIG. **17** in a closed position;
(35) FIG. **21**A is a perspective view of another exemplary embodiment of a screwless connection terminal for the receptacle of FIG. **17**, illustrating a wire manager secured to a clamp brace of a wire terminal;
(36) FIG. **21**B is a bottom perspective view of the screwless connection terminal of FIG. **21**A, illustrating the wire manager secured to the clamp brace;
(37) FIG. **22** is a top perspective view of the screwless connection terminal of FIG. **21** in an open position;
(38) FIG. **22**A is a top perspective view of the screwless connection terminal of FIG. **21**A in an open position and illustrating a stranded wire ready for insertion into the screwless connection terminal;
(39) FIG. **22**B is a perspective view of the screwless connection terminal of FIG. **22**A with the stranded wire inserted into the screwless connection terminal and the stranded wire resting in the

wire manager;
(40) FIG. **22**C is a bottom perspective view of the screwless connection terminal of FIG. **22**B, illustrating the screwless connection terminal in the closed position and the stranded wire resting in the wire manager;
(41) FIG. **22**D is an enlarged perspective view of a portion of the screwless connection terminal of FIG. **22**C taken from detail **22**D, illustrating the stranded wire resting in the wire manager;
(42) FIG. **23** is a top perspective view if another exemplary embodiment of an electrical receptacle having screwless connection terminals according to the present disclosure;
(43) FIG. **24** is a bottom perspective view of the receptacle of FIG. **23**;
(44) FIG. **25** is a bottom plan view of the receptacle of FIG. **24**;
(45) FIG. **26** is a cross sectional view of the receptacle of FIG. **25** taken along line **26**-**26**;
(46) FIG. **27** is a top perspective view if an exemplary embodiment of an electrical switch having screwless connection terminals according to the present disclosure;
(47) FIG. **28** is a bottom perspective view of the switch of FIG. **27**;
(48) FIG. **29** is a bottom plan view of the switch of FIG. **28**;
(49) FIG. **30** is a cross sectional view of the switch of FIG. **29** taken along line **30**-**30**;
(50) FIG. **31** is a top perspective view of another exemplary embodiment of a screwless connection terminal for the electrical switch of FIG. **27** in a closed position;
(51) FIG. **31**A is a perspective view of another exemplary embodiment of a screwless connection terminal for the receptacle of FIG. **27**, illustrating a wire manager secured to a clamp brace of a wire terminal;
(52) FIG. **31**B is a bottom perspective view of the screwless connection terminal of FIG. **31**A, illustrating the wire manager secured to the clamp brace;
(53) FIG. **32** is a top perspective view of the screwless connection terminal of FIG. **31** in an open position;
(54) FIG. **32**A is a top perspective view of the screwless connection terminal of FIG. **31**A in an open position and illustrating a stranded wire ready for insertion into the screwless connection terminal;
(55) FIG. **32**B is a perspective view of the screwless connection terminal of FIG. **32**A with the stranded wire inserted into the screwless connection terminal and the stranded wire resting in the wire manager;
(56) FIG. **32**C is a bottom perspective view of the screwless connection terminal of FIG. **32**B, illustrating the screwless connection terminal in the closed position and the stranded wire resting in the wire manager;
(57) FIG. **32**D is an enlarged perspective view of a portion of the screwless connection terminal of FIG. **32**C taken from detail **32**D, illustrating the stranded wire resting in the wire manager;
(58) FIG. **33** is a perspective view of an exemplary embodiment of an electrical male flanged inlet having screwless connection terminals according to the present disclosure, illustrating a plug assembly within an inlet housing;
(59) FIG. **34** is a perspective view of the electrical male flanged inlet of FIG. **33**, illustrating the plug assembly separated from the inlet housing;
(60) FIG. **35** is a side perspective view with parts separated of the plug assembly of the electrical male flanged inlet of FIG. **34**;
(61) FIG. **36** is a top perspective view of the contact assembly of FIG. **34**, illustrating a plurality of contact assemblies in a main body of the plug assembly;
(62) FIG. **37** is a top perspective view of the contact assembly of FIG. **18**, with a retainer secured to the main body of the plug assembly;
(63) FIG. **38** is a perspective view of an exemplary embodiment of an electrical female flanged receptacle having screwless connection terminals according to the present disclosure, illustrating a receptacle assembly within a receptacle housing;

(64) FIG. **39** is a perspective view of the electrical female flanged receptacle of FIG. **38**, illustrating the receptacle assembly separated from the receptacle housing;
(65) FIG. **40** is a side perspective view with parts separated of the receptacle assembly of the electrical female flanged receptacle of FIG. **39**;
(66) FIG. **41** is a top perspective view of the receptacle assembly of FIG. **40**, illustrating a plurality of contact assemblies in a main body of the receptacle assembly;
(67) FIG. **42** is a top perspective view of the contact assembly of FIG. **41**, with a retainer secured to the main body of the plug assembly;
(68) FIG. **43** is a perspective view of an exemplary embodiment of a wire manager of the clamp brace, and illustrating a portion of a surface of the clamp brace with a textured surface in the form of striations;
(69) FIG. **44** is a perspective view of another exemplary embodiment of a wire manager secured to the clamp brace, and illustrating a portion of a surface of the clamp brace with a textured surface in the form of knurling;
(70) FIG. **45** is a perspective view of another exemplary embodiment of a wire manager secured to the clamp brace, and illustrating a portion of a surface of the clamp brace with a textured surface in the form of shallow grooves;
(71) FIG. **46** is a perspective view of another exemplary embodiment of a wire manager according to the present disclosure, illustrating the wire manager associated with a clamp brace of a wire terminal; and
(72) FIG. **47** is a perspective view of another exemplary embodiment of a wire manager according to the present disclosure, illustrating the wire manager associated with a clamp member of a clamp spring of a wire terminal.

DETAILED DESCRIPTION

(73) Exemplary embodiments of electrical wiring devices that incorporate the screwless or clamp wire terminal of the present disclosure are shown and described. Non-limiting examples of the electrical wiring devices contemplated by the present disclosure include, single and duplex blade-type electrical receptacles, blade-type locking electrical receptacles, single or multi-pole electrical switches, combination switches and blade-type receptacles, blade-type plugs for electrical cords and blade-type connectors for electrical cords. Blade-type electrical wiring devices as described herein are; a) male blade-type electrical wiring devices with a plurality of non-circular, e.g., substantially flat or arcuate, power contact blades (hot and/or neutral contact blades) that can mate with corresponding finger contacts within a female blade-type electrical wiring device, or b) female blade-type electrical wiring devices with a plurality of non-circular, e.g., substantially flat or arcuate, power contact blade apertures (hot and/or neutral contact blade apertures) that provide access to contact fingers within the female electrical wiring devices that can mate with corresponding non-circular power contact blades of male blade-type electrical wiring devices. Examples of blade-type electrical wiring devices are described in NEMA standard WD6, which is publicly available and incorporated herein in its entirety by reference. In one exemplary embodiment, a blade-type electrical receptacle includes a housing and a plurality of female contact assemblies within the housing that are accessible from an exterior of the housing. In another exemplary embodiment, a blade-type electrical power cord connector includes a housing and a plurality of female contact assemblies within the housing that are accessible from an exterior of the housing and capable of receiving a plurality of blades of a plug. In another exemplary embodiment, a blade-type electrical power cord plug includes a housing and a plurality of male contact assemblies within the housing that extend beyond an exterior of the housing.
(74) In some embodiments, the housing has a front cover and a main body. In other embodiments, the housing has a front cover, a main body and a rear cover. In each embodiment of an electrical wiring device, each contact assembly has a contact member, a wire terminal and a plunger. The contact member is used to form a portion of a conductive electrical path. The wire terminal is used

to terminate an electrical conductor inserted into the housing, and the plunger moves the wire terminal between open and closed positions. The wire terminal includes a clamp brace, a contact arm and a clamp spring. The contact arm connects the wire terminal to the contact member, and the clamp spring is used to apply a constant and continuous load (or spring force) against an electrical conductor to electrically connect the electrical conductor to the clamp brace. The plunger is used to move the clamp spring between the open position permitting an electrical conductor to enter the wire terminal and the closed position binding or squeezing the electrical conductor within the wire terminal.

(75) For the purposes of the present disclosure, the electrical conductor may also be referred to as the “wire.” Further, the electrical conductor can be any size wire used to conduct electricity, such as 14 AWG wire, 12 AWG wire, 10 AWG wire or 8 AWG wire. Depending upon the number of conductors in a power cord, generally, 14 AWG wires are rated for between 15 and 18 amps, 12 AWG wires are rated for between 20 and 25 amps, 10 AWG wires are rated for between 25 and 30 amps, and 8 AWG wires are rated for between 35 and 40 amps.

(76) Referring now to FIGS. **1**-**9**, an exemplary embodiment of a locking blade type electrical receptacle is shown. In this exemplary embodiment, the receptacle **10** has a housing **20** and a plurality of contact assemblies **100**, seen in detail in FIGS. **8** and **9**, within the housing that are accessible from an exterior of the housing. The housing **20** has a main body **30**, a front cover **50** and a rear cover **70**. The front cover **50** is secured to one side of the main body **30** and the rear cover **70** is secured to the other side of the main body **30**. The housing **20** is made of a suitable electrical insulating material, such as plastic, including injection molded thermoplastic, and is configured to fit within an electrical box.

(77) The main body **30** includes a plurality of chambers or cavities **32**, seen in FIGS. **4** and **5**. Each cavity **32** is configured to receive and position a contact assembly **100** within the main body **30**, as shown in FIGS. **6** and **7**. Each contact assembly **100** is configured to receive a wire, such as wire **700** shown in FIG. **5**, and to mate with a contact blade of a plug connector, such as the plug connector of FIG. **17**.

(78) As shown in FIG. **1**, the front cover **50** of the receptacle **10** includes a face **52** having a plurality of blade-receiving slots **54** through which contact blades of a plug connector, such as the contact blades of the plug connector shown in FIG. **17**, can be inserted in the usual manner into adjacent cavities **32** within the main body **30**. The front cover **50** has one or more mounting straps **56** that are secured to an exterior surface of the front cover **50** using, for example, mechanical fasteners or adhesives. The mounting straps **56** are used to secure the receptacle **10** to an electrical box via apertures **58** as is known. The mounting straps **56** may also be connected to electrical ground via a contact assembly **100** within the main body **30**. The front cover **50** can be secured to the main body **30** using mechanical fasteners, adhesives or welds such as sonic welds.

(79) Referring to FIGS. **2**, **3** and **5**, the rear cover **70** can be secured to the main body **30** using mechanical fasteners, such as screws **72**, adhesives or welds such as sonic welds. The rear cover **70** includes a plurality of wire receiving apertures **74**. Each wire receiving aperture **74** is positioned to align with a cavity **32** in the main body **30** so that a wire can pass through the rear cover **70** into a contact assembly **100** resting within a cavity **32** in the main body **30**. The rear cover **70** may also include a plurality of wire guides **76** extending outwardly from an exterior surface **78** of the rear cover, as shown. In the embodiment shown, one wire guide **76** corresponds to one wire receiving aperture **74**. Each wire guide **76** has an arcuate shape that corresponds to the round shape of a wire being inserted into the wire receiving aperture **74**. The rear cover **70** also includes a plurality of plunger openings **80**, seen in FIGS. **2** and **3**, that permits a portion of a plunger **150**, forming a portion of the contact assembly **100** described below, to extend outside the housing **20**.

(80) Turning to FIGS. **8** and **9**, an exemplary embodiment of a contact assembly **100** according to the present disclosure is shown. In this exemplary embodiment, the contact assembly **100** includes a contact member **110**, a wire terminal **130** and a plunger **150**. The contact member **110** is made of

an electrically conductive material, such as brass, copper or aluminum. The wire terminal **130** is made of an electrically conductive resilient material with sufficient stiffness to flex when a mechanical load is applied and return to its normal position when the mechanical load is removed. An example of such an electrically conductive resilient material is spring steel. The plunger **150** is made of a suitable rigid electrical insulating material, such as plastic materials. An example of a plastic material is injection molded thermoplastic. The contact member **110** and the wire terminal **130** can be formed as a unitary structure, or the contact member **110** and wire terminal **130** can be individual components secured together by, for example, a solder joint, a brazed joint, or a welded joint.

(81) The contact member **110** includes a contact body **112** and a pair of flexible fingers **114** and **116** extending from the contact body **112**, as shown. The flexible fingers **114** and **116** form a female contact configured to engage a contact blade of a blade-type electrical power cord plug, such as a contact blade of the plug shown in FIG. **17**. The distal ends of the flexible fingers **114** and **116** contact each other or are in close proximity to each other to form a gripping portion **118** between the fingers. The gripping portion **118** is capable of receiving a contact blade so as to electrically couple or connect the contact member **110** to the contact blade. Thus, each contact assembly **100** is adapted to engage one of a plurality of contact blades of a blade-type electrical power cord plug.

(82) The wire terminal **130** is a mechanical clamping terminal that uses one or more springs that can deflect under a mechanical load applied by the plunger **150** and recover to their initial shape when the mechanical load is removed. The energy stored by the one or more springs should be sufficient to apply a constant and continuous force to mechanically secure one or more wires, e.g., wire **700** shown in FIG. **5**, to the wire terminal **130**.

(83) In the exemplary configuration shown in FIGS. **8** and **9**, the wire terminal **130** includes a clamp brace **132**, a contact arm **134** and a clamp spring **136**. The clamp brace **132** is a fixed terminal body that may be a substantially planar shaped member or an arcuate shaped member secured to the contact body **112** of the contact member **110** via the contact arm **134**. The contact arm **134** also provides an electrically conductive path between the contact member **110** and the wire terminal **130**. The clamp spring **136** includes an end portion **138**, a spring member **140** and a clamp arm **142**. The end portion **138** can be a substantially planar shaped member or an arcuate shaped member that is configured to mate with the clamp brace **132** and is secured to the clamp brace **132** by, for example, a solder joint, a brazed joint, or a welded joint. The spring member **140** has a lower lobe **140***a* and an upper lobe **140***b*. The lower lobe **140***a* and the upper lobe **140***b* are configured to interact with the plunger **150** so that vertical movement of the plunger **150** relative to the spring member **140** is translated to the application of a mechanical load on the spring member **140** or the removal of the mechanical load on the spring member **140**. For example, the plunger **150** can be a rectangular shaped member having a notch **152** that is configured to receive the upper lobe **140***b* of the spring member **140**, as shown in FIG. **8**. The notch **152** has a camming surface **152***a* that rides along the spring member **140** when the plunger **150** is moved in the direction of arrow “B” applying a mechanical load on the spring member **140** causing the spring member **140** to deflect in the direction of arrow “C” toward the open position, seen in FIG. **9**. The clamp arm **142** extends from the upper lobe **140***b* of the spring member **140** toward the clamp brace **132**, as shown. The clamp arm **142** has an elongated opening **144** configured to receive a portion of the clamp brace **132** and a clamp member **146** that contacts a wire, e.g., wire **700** seen in FIG. **5**, positioned between the clamp brace **132** and the clamp member **146** when the clamp spring **136** is in the closed position. The clamp arm **142** is movable relative to the clamp brace **132** between the closed position, seen in FIG. **8**, and the open position, seen in FIG. **9**.

(84) As noted, the wire terminal **130** can connect to electrical conductors of different sizes. For example, if the blade-type electrical receptacle **10** is rated for 15 amps, then the wire terminal **130** should also be configured and rated for at least 15 amps. The wire size, i.e., the bare conductor size, for 15 amps is 14 AWG wire such that the clamp arm **142** should be able to move to an open

position where the outer diameter of 14 AWG wire can fit. As another example, if the blade-type electrical receptacle **10** is rated for 20 amps, then the wire terminal **130** should also be rated for at least 20 amps. The wire size, i.e., the bare conductor size, for 20 amps is 12 AWG wire such that the clamp arm **142** should be able to move to an open position where the outer diameter of 12 AWG wire can fit. As another example, if the blade-type electrical receptacle **10** is rated for 30 amps, then the wire terminal **130** should also be rated for at least 30 amps. The wire size, i.e., the bare conductor size, for 30 amps is 10 AWG wire such that the clamp arm **142** should be able to move to an open position where the outer diameter of 10 AWG wire can fit. As another example, if the blade-type electrical receptacle **10** is rated for 40 amps, then the wire terminal **130** should also be rated for at least 40 amps. The wire size, i.e., the bare conductor size, for 40 amps is 8 AWG wire such that the clamp arm **142** should be able to move to an open position where the outer diameter of 8 AWG wire can fit.

(85) As noted, the spring member **140** is made of an electrically conductive resilient material with sufficient stiffness to flex when the plunger **150** pushes the spring member **140** from the closed position to the open position while applying a biasing force (i.e., a spring force) through the clamp member **146** to a wire between the clamp member **146** and the clamp brace **132**. As an example, the spring arm **140** can be made of metal, such as spring steel. The biasing force (or spring force) exerted by the spring arm **140** clamping a wire between the clamp member **146** and the clamp brace **132** should be sufficient to apply a constant and continuous force on the wire to electrically couple or connect the wire terminal **130** to the wire in various temperature and environmental conditions. The spring member **140** is configured so that it is normally biased toward the closed position, i.e., in the direction of arrow “A” which is away from the clamp brace **132**, as seen in FIG. **8**. In the spring member's **140** normal position without a conductor inserted into the elongated opening **144**, the clamp member **146** of the clamp arm **142** can contact the clamp brace **132**.

(86) Turning to FIGS. **8**A, **8**B and **9**A-**9**D, another exemplary embodiment of a contact assembly **101** according to the present disclosure is shown. The contact assembly **101** is substantially similar to the contact assembly **100** such that like reference numerals are used to reference like components. The contact assembly **101** includes the contact member **110**, the wire terminal **130** and the plunger **50**. In this exemplary embodiment, the wire terminal **130** includes a wire manager **900**.

(87) The wire terminal **130** is a mechanical clamping terminal that uses, for example, one or more springs that can deflect under a mechanical load applied by the plunger **150** and recover to its initial shape when the mechanical load is removed. The energy stored by the one or more springs should be sufficient to apply a constant and continuous force in the range of, for example, about 5 pound force to about 35 pound force, to mechanically secure one or more wires, e.g., wire **710** shown in FIG. **9**A, to the wire terminal **130**. The wire terminal **130** is made of an electrically conductive resilient material with sufficient stiffness to flex when a mechanical load is applied and return to its normal position when the mechanical load is removed. An example of such an electrically conductive resilient material is spring steel. In the exemplary configuration shown in FIGS. **8**A and **8**B, the wire terminal **130** includes a clamp brace **132**, a contact arm **134** and a clamp spring **136**. The clamp brace **132** is a fixed terminal body that may be a substantially planar shaped member or an arcuate shaped member secured to or integrally formed into the contact body **112** of the contact member **110** via the contact arm **134**. The clamp spring **136** includes an end portion **138**, a spring member **140** and a clamp arm **142**. The clamp arm **142** has an elongated opening **144** configured to receive a portion of the clamp brace **132** and a clamp member **146** that contacts a wire, e.g., wire **710** seen in FIG. **9**A, positioned within the elongated opening **144** between the clamp brace **132** and the clamp member **146** when the clamp spring **136** is in the closed position. The clamp arm **142** is movable relative to the clamp brace **132** between the closed position, seen in FIG. **8**A, and the open position, seen in FIG. **9**A.

(88) In this exemplary embodiment, the clamp brace **132** has a wire manager **900** integrally or monolithically formed into the clamp brace **132**. In another embodiment, the wire manager **900**

may be secured to the clamp brace **132** by, for example, a solder joint, a brazed joint or a welded joint. It is to be appreciated that the wire manager **900** may also be integrally or monolithically formed into the clamp spring **136**. It is also to be appreciated that the wire manager **900** may also be secured to the clamp spring **136** by, for example, a solder joint, a brazed joint or a welded joint. The wire manager **900** is provided to urge the wire, e.g., wire **700** or **710**, to be concentrated toward a center or middle of the clamp brace **132** and/or a center or middle of the clamp member **146**. Preferably, the wire manager **900** is provided to urge wire strands of stranded wire, e.g., stranded wire **710**, to be concentrated toward a center or middle the clamp brace **132** and/or a center or middle of the clamp member **146**. Concentrating the wire, e.g., wire strands of stranded wire **710**, toward a middle the clamp brace **132** and/or a middle of the clamp member **146** increases the force or pressure applied by the clamp member **146** of the clamp arm **142** of the clamp spring **136** to the wire. For example, concentrating the wire toward a middle the clamp brace **132** and/or a middle of the clamp member **146** can increase the force or pressure applied by the clamp member **146** by, for example, about 20 percent when compared to instances where the wire, e.g., wire **710**, is not concentrated wire toward a center or middle the clamp brace **132** and/or a center or middle of the clamp member **146**. This results in a higher wire retention force in the range of about 1 pound force and about 7 pound force that can be applied by the clamp spring **136** to hold the wire, e.g., the wire strands of the stranded wire **710**, against the clamp brace **132**. For example, in the example where the energy stored by the one or more springs should be sufficient to apply a constant and continuous force in the range of, for example, about 5 pound force to about 35 pound force, the higher wire retention force would be in the range of, for example, 6 pound force to about 42 pound force. In addition, the higher spring force or pressure on the wire also provides an improved electrical connection by lowering the contact resistance. Exemplary embodiments of the wire manager **900** are shown in FIGS. **43-47** and are described herein below. However, the present disclosure contemplates other wire manager embodiments where the wire manager urges a wire or wire strands toward a center or middle of a clamp brace and/or a center or middle of the clamp member.

(89) As noted, the wire terminal **130** can connect to electrical conductors of different sizes. For example, if the blade-type electrical receptacle **10** is rated for 15 amps, then the wire terminal **130** should also be configured and rated for at least 15 amps. The wire size, i.e., the bare conductor size, for 15 amps is 14 AWG wire such that the clamp arm **142** should be able to move to an open position where the outer diameter of 14 AWG wire can fit. As another example, if the blade-type electrical receptacle **10** is rated for 20 amps, then the wire terminal **130** should also be rated for at least 20 amps. The wire size, i.e., the bare conductor size, for 20 amps is 12 AWG wire such that the clamp arm **142** should be able to move to an open position where the outer diameter of 12 AWG wire can fit. As another example, if the blade-type electrical receptacle **10** is rated for 30 amps, then the wire terminal **130** should also be rated for at least 30 amps. The wire size, i.e., the bare conductor size, for 30 amps is 10 AWG wire such that the clamp arm **142** should be able to move to an open position where the outer diameter of 10 AWG wire can fit. As another example, if the blade-type electrical receptacle **10** is rated for 40 amps, then the wire terminal **130** should also be rated for at least 40 amps. The wire size, i.e., the bare conductor size, for 40 amps is 8 AWG wire such that the clamp arm **142** should be able to move to an open position where the outer diameter of 8 AWG wire can fit.

(90) As noted, the spring member **140** is made of a resilient material with sufficient stiffness to flex when the plunger **150** pushes the spring member **140** from the closed position to the open position while applying a biasing force (i.e., a spring force) through the clamp member **146** to a wire between the clamp member **146** and the clamp brace **132**. As an example, the spring arm **140** can be made of metal, such as spring steel. The biasing force (or spring force) exerted by the spring arm **140** clamping a wire between the clamp member **146** and the clamp brace **132** should be sufficient to apply a constant and continuous force on the wire to electrically couple or connect the wire

terminal **130** to the wire in various temperature and environmental conditions. The spring member **140** is configured so that it is normally biased toward the closed position, i.e., in the direction of arrow “A” which is away from the clamp brace **132**, as seen in FIG. **8**. In the spring member's **140** normal position without a conductor inserted into the elongated opening **144**, the clamp member **146** of the clamp arm **142** can contact the clamp brace **132**.

(91) As described herein, the receptacle **10** uses contact assemblies **100** to terminate electrical conductors or wires within an electrical box. To connect wires within an electrical box to the receptacle **10**, an installer, e.g., an electrician, strips the insulation from the end of each wire. In this exemplary embodiment, the receptacle **10** has three contact assemblies **100** such that three wires can be connected to the receptacle **10**. However, it is also contemplated that each contact assembly could be configured to electrically connect more than one wire to the contact assembly **100**. The plungers **150** for each contact assembly **100** extending through the rear cover **70** are then pulled vertically relative to a longitudinal axis of the receptacle **10**, i.e., in the direction of arrow “B” seen in FIG. **8**, to cause the camming surface **152***a* of the notch **152** in the plunger **150** to ride along the spring member **140** applying a mechanical load on the spring member **140** causing the spring member to deflect in the direction of arrow “C” from the closed position toward the open position, seen in FIG. **9**. With the wire terminals **130** in the open position, the electrical wires are then inserted into the appropriate wire receiving aperture **74** in the rear cover **70** of the receptacle **10**. The wire receiving apertures **74** and wire guides **76** guide the bare end of the wires into the portion of the elongated opening **144** of the clamp spring **136** between clamp brace **132** and clamp member **146**. When the bare end of each wire is positioned between the clamp brace **132** and the clamp member **146**, the respective plunger **150** is then pushed back into the receptacle **10** removing the mechanical load applied by the plunger on the spring member **140** so that the energy stored by the spring member **140** moves the spring member **140** to the closed position securing or clamping the wire between the clamp brace **132** and the clamp member **146** completing an electrically conductive path between the wire and the contact member **110**.

(92) To remove the wires from the contact assembly **100**, the plungers **150** for each contact assembly **100** extending through the rear cover **70** are pulled vertically relative to a longitudinal axis of the receptacle **10** to cause the camming surface **152***a* of the notch **152** in the plunger **150** to ride along the spring member **140** applying a mechanical load on the spring member **140** causing the spring member to deflect from the closed position to the open position. With the wire terminals **130** in the open position, the electrical wires can be removed from the receptacle.

(93) Referring now to FIGS. **10-16**, an exemplary embodiment of a blade-type electrical power cord connector is shown. In this exemplary embodiment, the blade-type connector **200** has a housing **210** and a plurality of contact assemblies **300** within the housing that are accessible from an exterior of the housing. The housing **210** has a main body **220**, a retainer **240** and a cover **260**. The retainer **240** is secured to a top side of the main body **220** using screw **242**. The cover **260** is secured to the top side of the main body **220** using screws **222** inserted through apertures in a face **224** in the main body **220** and through the main body **220**. The housing **210** is made of a suitably rigid, electrical insulating material, such as a plastic material, including injection molded thermoplastic, or a rubber material.

(94) The main body **220** includes a plurality of chambers or cavities **226** seen in FIGS. **12** and **13**. Each cavity **226** is configured to receive and position a contact assembly **300** within the main body **220**. Each contact assembly **300** is configured to receive a conductor and to mate with a contact blade of a blade-type plug connector, such as a contact blade of the plug connector of FIG. **17**. The face **224** of the main body **220** has a plurality of blade-receiving slots **228** through which contact blades of a blade-type plug connector can be inserted in the usual manner into adjacent cavities **226** within the main body **220** and into a respective contact assembly **300**.

(95) The cover **260** of the connector **200** may be hollow, partially hollow or solid. As shown in FIGS. **10** and **12**, the cover **260** includes a cable connector **262** at a top portion of the cover **260**.

The cable connector **262** includes a fixed bracket **264** and a movable bracket **266** releasably secured to the fixed bracket **264** using screws **268**. In a central portion of the connector **262** is a cable receiving opening **270** that extends through the cover **260**. The cable receiving opening **270** permits an electrical power cord (not shown) to pass through the cover **260** so that electrical wires within the electrical power cord can be connected to the contact assemblies **300**.

(96) Referring to FIGS. **12** and **14**, the retainer **240** is secured to the main body **220** using mechanical fasteners, such as screw **242**. The retainer **240** includes a plurality of wire receiving apertures **244**. Each wire receiving aperture **244** is positioned to align with a cavity **226** in the main body **220** so that a wire can pass through the retainer **240** into a contact assembly **300** resting within a cavity **226** in the main body **220**. The retainer **240** may also include a plurality of wire guides **246** extending outwardly from surface **248** of the retainer, as shown. In the embodiment shown, one wire guide **246** corresponds to one wire receiving aperture **244**. Each wire guide **246** may have an arcuate like shape that corresponds to the shape of a wire being inserted into the wire receiving aperture **244**. The retainer **240** also includes a plurality of plunger openings **250**, seen in FIG. **14**. In the embodiment shown, one plunger opening **250** corresponds to one wire receiving aperture **244**. The plunger openings **250** permit a portion of a respective plunger **350** forming a portion of the contact assembly **300**, described below, to extend outside the main body **220**. The retainer **240** may also include a plurality of plunger guides **254** extending outwardly from surface **252** of the retainer, as shown in FIG. **12**. In the embodiment shown, one plunger guide **254** corresponds to one plunger opening **250**. The plunger guides **254** guide the plungers **350** as they are moved relative to the retainer **240**.

(97) Referring to FIGS. **15** and **16**, another exemplary embodiment of a contact assembly **300** according to the present disclosure is shown. In this exemplary embodiment, the contact assembly **300** includes a contact member **310**, a wire terminal **330** and a plunger **350**. The contact member **310** is made of an electrically conductive material, such as brass, copper or aluminum. The wire terminal **330** is made of an electrically conductive resilient material with sufficient stiffness to flex when a mechanical load is applied to the material and return to its normal position when the mechanical load is removed. An example of an electrically conductive resilient material is spring steel. The plunger **350** is made of a suitable rigid electrical insulating material, such as plastic materials. An example of a plastic material is injection molded thermoplastic. The contact member **310** and wire terminal **330** can be formed as a unitary structure, or the contact member and wire terminal can be individual components secured together by, for example, a solder joint, a brazed joint, or a welded joint.

(98) The contact member **310** includes a contact body **312** and a pair of flexible fingers **314** and **316** extending from the contact body **312**, as shown. The flexible fingers **314** and **316** form a female contact configured to engage a contact blade of a blade-type electrical power cord plug, such as a contact blade of the plug shown in FIG. **17**. The distal end of the flexible fingers **314** and **316** contact each other or are in close proximity to each other to form a gripping portion **318** between the fingers. The gripping portion **318** is capable of receiving a contact blade so as to electrically couple or connect the contact member **310** to the contact blade. Thus, each contact assembly **300** is adapted to engage one of a plurality of contact blades of a blade-type electrical power cord plug.

(99) The wire terminal **330** is a mechanical clamping terminal that uses one or more springs that can deflect under a mechanical load applied by the plunger **350** and recover to their initial shape when the mechanical load is removed. The energy stored by the one or more springs should be sufficient to apply a constant and continuous force to mechanically secure one or more wires, e.g., wire **700** shown in FIG. **16**, to the wire terminal **330**.

(100) In the exemplary configuration shown in FIGS. **15** and **16**, the wire terminal **330** includes a clamp brace **332** and a clamp spring **336**. The clamp brace **332** is a fixed terminal body that may be a substantially planar shaped member or an arcuate shaped member secured to or integrally formed

into the contact body **312** of the contact member **310**. The clamp brace **332** also forms an electrically conductive path between the contact body **312** and the clamp brace **332**. The clamp spring **336** includes an end portion **338**, a spring member **340** and a clamp arm **342**. The end portion **338** can be a substantially planar shaped member or an arcuate shaped member that is configured to mate with the clamp brace **332** and is secured to the clamp brace by, for example, a solder joint, a brazed joint, or a welded joint. The spring member **340** has a lower lobe **340***a* and an upper lobe **340***b*. The lower lobe **340***a* and the upper lobe **340***b* are configured to interact with the plunger **350** so that vertical movement of the plunger relative to the spring member **340** is translated to the application of a mechanical load on the spring member **340** or the removal of the mechanical load on the spring member **340**. For example, the plunger **350** can be a rectangular shaped member having a notch **352** that is configured to receive the upper lobe **340***b* of the spring member **340**, as shown in FIG. **15**. The notch **352** has a camming surface **352***a* that rides along the spring member **340** when the plunger **350** is moved in the direction of arrow "E" applying a mechanical load on the spring member **340** causing the spring member **340** to deflect in the direction of arrow "F" toward the open position, seen in FIG. **16**. The clamp arm **342** extends from the upper lobe **340***b* of the spring member **340** toward the clamp brace **332**, as shown. The clamp arm **342** has an elongated opening **344** configured to receive a portion of the clamp brace **332** and a clamp member **346** that contacts a wire, e.g., wire **700** seen in FIG. **16**, positioned between the clamp brace **332** and the clamp member **346** when the clamp spring **336** is in the closed position, seen in FIG. **15**. The clamp arm **342** is movable relative to the clamp brace **332** between the closed position, seen in FIG. **15**, and the open position, seen in FIG. **16**.

(101) Turning to FIGS. **15**A, **1513** and **16**A-**16**D, another exemplary embodiment of a contact assembly **301** according to the present disclosure is shown. The contact assembly **301** is substantially similar to the contact assembly **300** such that like reference numerals are used to reference like components. The contact assembly **301** includes the contact member **310**, the wire terminal **330** and the plunger **350**. In this exemplary embodiment, the wire terminal **130** includes a wire manager **900**.

(102) The wire terminal **330** is a mechanical clamping terminal that uses, for example, one or more springs that can deflect under a mechanical load applied by the plunger **350** and recover to its initial shape when the mechanical load is removed. The energy stored by the one or more springs should be sufficient to apply a constant and continuous force in the range of, for example, about 5 pound force to about 35 pound force, to mechanically secure one or more wires, e.g., wire **710** shown in FIG. **16**A, to the wire terminal **330**. In this exemplary embodiment, the wire terminal **330** is made of an electrically conductive resilient material with sufficient stiffness to flex when a mechanical load is applied and return to its normal position when the mechanical load is removed. An example of such an electrically conductive resilient material is spring steel. In the exemplary configuration shown in FIGS. **15**A and **15**B, the wire terminal **330** includes the clamp brace **332**, the contact arm **334** and the clamp spring **336**. The clamp brace **332** is a fixed terminal body that may be a substantially planar shaped member or an arcuate shaped member secured to or integrally formed into the contact body **312** of the contact member **310**. The clamp spring **336** includes an end portion, the spring member **340** and the clamp arm **342**. The clamp arm **342** has the elongated opening **344** configured to receive a portion of the clamp brace **332** and the clamp member **346** that contacts a wire, e.g., the wire strands of stranded wire **710** seen in FIG. **16**A, positioned within the elongated opening **344** between the clamp brace **332** and the clamp member **346** when the clamp spring **336** is in the closed position. The clamp arm **342** is movable relative to the clamp brace **332** between the closed position, seen in FIG. **15**A, and the open position, seen in FIG. **16**A.

(103) In this exemplary embodiment, the clamp brace **332** has a wire manager **900** integrally or monolithically formed into the clamp brace **332**. In another embodiment, the wire manager **900** may be secured to the clamp brace **332** by, for example, a solder joint, a brazed joint or a welded joint. It is to be appreciated that the wire manager **900** may also be integrally or monolithically

formed into the clamp spring **336**. It is also to be appreciated that the wire manager **900** may also be secured to the clamp spring **336** by, for example, a solder joint, a brazed joint or a welded joint. The wire manager **900** is provided to urge the wire, e.g., wire **700** or the wire strands of stranded wire **710**, to be concentrated toward a center or middle of the clamp brace **332** and/or a center or middle of the clamp member **346**. Preferably, the wire manager **900** is provided to urge wire strands of stranded wire, e.g., stranded wire **710**, to be concentrated toward a center or middle the clamp brace **332** and/or a center or middle of the clamp member **346**. Concentrating the wire, e.g., wire strands of stranded wire **710**, toward a middle the clamp brace **332** and/or a middle of the clamp member **346** increases the force or pressure applied by the clamp member **346** of the clamp arm **342** of the clamp spring **336** to the wire. For example, concentrating the wire toward a middle the clamp brace **332** and/or a middle of the clamp member **346** can increase the force or pressure applied by the clamp member **346** by, for example, about 20 percent when compared to instances where the wire, e.g., wire **710**, is not concentrated wire toward a center or middle the clamp brace **332** and/or a center or middle of the clamp member **346**. This results in a higher wire retention force in the range of, for example, about 1 pound force and about 7 pound force that can be applied by the clamp spring **336** to hold the wire, e.g., the wire strands of the stranded wire **710** against the clamp brace **332**. For example, in the example where the energy stored by the one or more springs should be sufficient to apply a constant and continuous force in the range of, for example, about 5 pound force to about 35 pound force, the higher wire retention force would be in the range of, for example, 6 pound force to about 42 pound force. In addition, the higher spring force or pressure on the wire also provides an improved electrical connection by lowering the contact resistance. Exemplary embodiments of the wire manager **900** are shown in FIGS. **43-47** and are described herein below. However, the present disclosure contemplates other wire manager embodiments where the wire manager urges a wire or wire strands toward a center or middle of a clamp brace and/or a center or middle of the clamp member.

(104) As noted, the wire terminal **330** can connect to electrical conductors of different sizes. For example, if the blade-type connector **200** is rated for 15 amps, then the wire terminal **330** should also be configured and rated for at least 15 amps. The wire size, i.e., the bare conductor size, for 15 amps is 14 AWG wire such that the clamp arm **342** should be able to move to an open position where the outer diameter of 14 AWG wire can fit. As another example, if the blade-type connector **200** is rated for 20 amps, then the wire terminal **330** should also be rated for at least 20 amps. The wire size, i.e., the bare conductor size, for 20 amps is 12 AWG wire such that the clamp arm **342** should be able to move to an open position where the outer diameter of 12 AWG wire can fit. As another example, if the blade-type connector **200** is rated for 30 amps, then the wire terminal **330** should also be rated for at least 30 amps. The wire size, i.e., the bare conductor size, for 30 amps is 10 AWG wire such that the clamp arm **342** should be able to move to an open position where the outer diameter of 10 AWG wire can fit. As another example, if the blade-type connector **200** is rated for 40 amps, then the wire terminal **330** should also be rated for at least 40 amps. The wire size, i.e., the bare conductor size, for 40 amps is 8 AWG wire such that the clamp arm **342** should be able to move to an open position where the outer diameter of 8 AWG wire can fit.

(105) As noted, the spring member **340** is made of an electrically conductive resilient material with sufficient stiffness to flex when the plunger **350** pushes the spring member **340** from the closed position to the open position while applying a biasing force (i.e., a spring force) to the clamp member **346** to secure or clamp a wire between the clamp member **346** and the clamp brace **332**. As an example, the spring arm **340** can be made of metal, such as spring steel. The biasing force (or spring force) exerted by the spring arm **340** clamping a wire between the clamp member **346** and the clamp brace **332** should be sufficient to apply a constant and continuous force on the wire to electrically couple or connect the wire terminal **330** to the wire in various temperature and environmental conditions. The spring member **340** is configured so that it is normally biased toward the closed position, i.e., in the direction of arrow “D” which is away from the clamp brace

332, as seen in FIG. **15**. In the spring member's **340** normal position without a conductor inserted into the elongated opening **344**, the clamp member **346** of the clamp arm **342** can contact the clamp brace **332**.

(106) As described herein, the connector **200** uses the contact assemblies **300** to terminate electrical wires within the connector. To connect wires within the connector **200**, an installer, e.g., an electrician, passes a wire cable through the cable receiving opening **270** in cover **260**. The insulation at the end of each wire within the cable is then striped. In this exemplary embodiment, the connector **200** has three contact assemblies **300** such that three wires within the wire cable can be connected to the connector. The portion of the plungers **350** for each contact assembly **300** extending through the retainer **240** are then pulled vertically relative to a longitudinal axis of the connector **200**, i.e., in the direction of arrow "E" seen in FIG. **15**, to cause the camming surface **352***a* of the notch **352** in the plunger **350** to ride along the spring member **340** applying a mechanical load on the spring member **340**. Applying a mechanical load to the spring member **340** in such a manner causes the spring member **340** to deflect in the direction of arrow "F" (i.e., from the closed position toward the open position), seen in FIG. **16**. With the wire terminals **330** in the open position, the electrical wires are then inserted into the appropriate wire receiving aperture **244** in the retainer **240** of the connector **200**. The wire receiving apertures **244** and wire guides **246** guide the bare end of the wires into the portion of the elongated opening **344** of the clamp spring **336** between clamp brace **332** and clamp member **346**. When the bare end of each wire is positioned between the clamp brace **332** and the clamp member **346**, the respective plunger **350** is then pushed back toward the main body **220** removing the mechanical load applied by the plunger **350** on the spring member **340** so that the energy stored by the spring member **340** biases the spring member **340** toward the closed position securing the wire between the clamp brace **332** and the clamp member **346**, and completing an electrically conductive path between the wire and the contact member **310**. To remove the wires from the contact assembly **300**, the plungers **350** for each contact assembly **300** extending through the retainer **240** are pulled vertically relative to a longitudinal axis of the connector **200** to cause the camming surface **352***a* of the notch **352** in the plunger **350** to ride along the spring member **340** applying a mechanical load on the spring member **340** causing the spring member **340** to deflect from the closed position to the open position. With the wire terminals **330** in the open position, the electrical wires can be removed from the connector **200**.

(107) Referring now to FIGS. **17**-**22**, an exemplary embodiment of a blade-type electrical power cord plug is shown. In this exemplary embodiment, the blade-type plug **400** has a housing **410** and a plurality of contact assemblies **500** within the housing **410** and extending at least partially from an exterior of the housing **410**. As seen in FIG. **18**, the housing **410** has a main body **420**, a bottom cover **440**, a retainer **460** and a top cover **480**. The retainer **460** is secured to a top side of the main body **420** using screw **462**. The bottom cover **440** is secured to the top cover **480** by passing screws **442** through a face **444** and apertures **446** in the bottom cover **440**, through corresponding apertures **422** in the main body **420** and through corresponding apertures **464** in the retainer **460**. The screws **442** are then secured to corresponding mounting holes (not shown) in the top cover **480**. The housing **410** is made of a suitably rigid, electrical insulating material, such as a plastic material, or a rubber material. An example of a plastic material is injection molded thermoplastic.

(108) The main body **420** includes a plurality of chambers or cavities **424** seen in FIGS. **18** and **19**. Each cavity **424** is configured to receive and position a contact assembly **500** within the main body **420**. Each contact assembly **500** is configured to receive a conductor and to mate with a female contact of a blade-type connector, such as the female contacts of FIG. **8** or **15**. The face **444** of the bottom cover **440** has a plurality of blade-receiving slots **448** through which contact blades **514** of the contact assemblies **500** can be inserted so that the contact blades extend outside the housing **410**.

(109) The bottom cover **440** when secured to the top cover **480** helps hold the contact assemblies

500 within the main body **420**. The top cover **480** of the connector **400** may be hollow, partially hollow or solid. As shown in FIGS. **17** and **18**, the cover **480** includes a cable connector **482** at a top portion of the cover **480**. The cable connector **482** includes a fixed bracket **484** and a movable bracket **486** releasably secured to the fixed bracket using screws **488**. In a central portion of the connector **482** is a cable receiving opening **490** that extends through the cover **480**. The cable receiving opening **490** permits an electrical power cord (not shown) to pass through the cover **480** so that electrical wires within the electrical power cord can be connected to the contact assemblies **500**.

(110) Referring to FIGS. **18** and **20**, the retainer **460** is secured to the main body **420** using mechanical fasteners, such as screw **462**. The retainer **460** includes a plurality of wire receiving apertures **466**. Each wire receiving aperture **466** is positioned to align with a cavity **424** in the main body **420** so that a wire can pass through the retainer **460** into a contact assembly **500** resting within a cavity **424** in the main body **420**. The retainer **460** may also include a plurality of wire guides **468** extending outwardly from surface **470** of the retainer **460**, as shown. In the embodiment shown, one wire guide **468** corresponds to one wire receiving aperture **466**. Each wire guide **468** may have an arcuate like shape that corresponds to the shape of a wire being inserted into the wire receiving aperture **466**. The retainer **460** also includes a plurality of plunger openings **472**. In the embodiment shown, one plunger opening **472** corresponds to one wire receiving aperture **466**. The plunger openings **472** permit a portion of a respective plunger **550** forming a portion of the contact assembly **500** described below, to extend outside the main body **420** and into the top cover **480**.

(111) Referring now to FIGS. **21** and **22**, another exemplary embodiment of a contact assembly **500** according to the present disclosure is shown. In this exemplary embodiment, the contact assembly **500** includes a contact member **510**, a wire terminal **530** and a plunger **550**. The contact member **510** is made of an electrically conductive material, such as brass, copper or aluminum. The wire terminal **530** is made of an electrically conductive resilient material with sufficient stiffness to flex when a mechanical load is applied and return to its normal position when the mechanical load is removed. An example of an electrically conductive resilient material is spring steel. The plunger **550** is made of a rigid electrical insulating material, such as a plastic material. An example of a plastic material is injection molded thermoplastic. The contact member **510** and wire terminal **530** can be formed as a unitary structure, or the contact member **510** and wire terminal **530** can be individual components secured together by, for example, a solder joint, a brazed joint, or a welded joint.

(112) The contact member **510** includes a contact body **512** and a blade **514** extending from the contact body **512**, as shown. The blade **514** is non-circular in shape and may be, for example, substantially flat in shape, arcuate in shape, L-shape or U-shape. The blade **514** forms a male contact configured to engage a female contact of a blade-type receptacle or a blade-type electrical power cord connector. The wire terminal **530** is a mechanical clamping terminal that uses one or more springs that can deflect under a mechanical load applied by the plunger **550** and recover to their initial shape when the mechanical load is removed. The energy stored by the one or more springs should be sufficient to apply a constant and continuous force to mechanically secure one or more wires, e.g., wire **700** shown in FIG. **22**, to the wire terminal **530**.

(113) In the exemplary configuration shown in FIGS. **21** and **22**, the wire terminal **530** includes a clamp brace **532** and a clamp spring **536**. The clamp brace **532** is a fixed terminal body that may be a substantially planar shaped member or an arcuate shaped member secured to or integrally formed into the contact body **512** of the contact member **510**. The clamp brace **532** also provides an electrically conductive path between the contact body **512** and the clamp brace **532**. The clamp spring **536** includes an end portion, a spring member **540** and a clamp arm **542**. The end portion can be a substantially planar shaped member or an arcuate shaped member that is configured to mate with the clamp brace **532** and is secured to the clamp brace **532** by, for example, a solder joint, a brazed joint, or a welded joint. The spring member **540** has a lower lobe **540***a* and an upper

lobe **540***b*. The lower lobe **540***a* and the upper lobe **540***b* are configured to interact with the plunger **550** so that vertical movement of the plunger **550** relative to the spring member **540** is translated to the application of a mechanical load on the spring member **540** or the removal of the mechanical load on the spring member **540**. For example, the plunger **550** can be a rectangular shaped member having a notch **552** that is configured to receive the upper lobe **540***b* of the spring member **540**, as shown in FIG. **21**. The notch **552** has a camming surface **552***a* that rides along the spring member **540** when the plunger **550** is moved in the direction of arrow "H" applying a load on the spring member **540** causing the spring member **540** to deflect in the direction of arrow "I" toward the open position, seen in FIG. **22**. The clamp arm **542** extends from the upper lobe **540***b* of the spring member **540** toward the clamp brace **532**, as shown. The clamp arm **542** has an elongated opening **544** configured to receive a portion of the clamp brace **532** and a clamp member **546** that contacts a wire, e.g., wire **700** seen in FIG. **22**, positioned between the clamp brace **532** and the clamp member **546** when the clamp spring **536** is in the closed position. The clamp arm **542** is movable relative to the clamp brace **532** between the closed position, seen in FIG. **21**, and the open position, seen in FIG. **22**.

(114) Turning to FIGS. **21**A, **21**B and **22**A-**22**D, another exemplary embodiment of a contact assembly **501** according to the present disclosure is shown. The contact assembly **501** is substantially similar to the contact assembly **500** such that like reference numerals are used to reference like components. The contact assembly **501** includes the contact member **510**, the wire terminal **530** and the plunger **550**. In this exemplary embodiment, the wire terminal **530** includes a wire manager **900**.

(115) The wire terminal **530** is a mechanical clamping terminal that uses, for example, one or more springs that can deflect under a mechanical load applied by the plunger **550** and recover to its initial shape when the mechanical load is removed. The energy stored by the one or more springs should be sufficient to apply a constant and continuous force in the range of, for example, about 5 pound force to about 35 pound force, to mechanically secure one or more wires, e.g., wire **710** shown in FIG. **22**A, to the wire terminal **530**. In this exemplary embodiment, the wire terminal **530** is made of an electrically conductive resilient material with sufficient stiffness to flex when a mechanical load is applied and return to its normal position when the mechanical load is removed. An example of such an electrically conductive resilient material is spring steel.

(116) In the exemplary configuration shown in FIGS. **21**A and **21**B, the wire terminal **530** includes the clamp brace **532** and a clamp spring **536**. The clamp brace **532** is a fixed terminal body that may be a substantially planar shaped member or an arcuate shaped member secured to or integrally formed into the contact body **512** of the contact member **510**. The clamp spring **536** includes an end portion, the spring member **540** and the clamp arm **542**. The clamp arm **542** has an elongated opening **544** configured to receive a portion of the clamp brace **532** and the clamp member **546** that contacts a wire, e.g., wire **710** seen in FIG. **22**A, positioned within the elongated opening **544** between the clamp brace **532** and the clamp member **546** when the clamp spring **536** is in the closed position. The clamp arm **542** is movable relative to the clamp brace **532** between the closed position, seen in FIG. **21**A, and the open position, seen in FIG. **22**A.

(117) In this exemplary embodiment, the clamp brace **532** has a wire manager **900** integrally or monolithically formed into the clamp brace **532**. In another embodiment, the wire manager **900** may be secured to the clamp brace **532** by, for example, a solder joint, a brazed joint or a welded joint. It is to be appreciated that the wire manager **900** may also be integrally or monolithically formed into the clamp spring **536**. It is also to be appreciated that the wire manager **900** may also be secured to the clamp spring **536** by, for example, a solder joint, a brazed joint or a welded joint. The wire manager **900** is provided to urge the wire, e.g., wire **700** or the wire strands of the stranded wire **710**, to be concentrated toward a center or middle of the clamp brace **532** and/or a center or middle of the clamp member **546**. Preferably, the wire manager **900** is provided to urge wire strands of stranded wire, e.g., stranded wire **710**, to be concentrated toward a center or middle

the clamp brace **532** and/or a center or middle of the clamp member **546**. Concentrating the wire, e.g., wire strands of stranded wire **710**, toward a middle the clamp brace **532** and/or a middle of the clamp member **546** increases the force or pressure applied by the clamp member **546** of the clamp arm **542** of the clamp spring **536** to the wire. For example, concentrating the wire toward a middle the clamp brace **532** and/or a middle of the clamp member **546** can increase the force or pressure applied by the clamp member **546** by, for example, about 20 percent when compared to instances where the wire, e.g., wire **710**, is not concentrated wire toward a center or middle the clamp brace **532** and/or a center or middle of the clamp member **546**. This results in a higher wire retention force in the range of, for example, about 1 pound force and about 7 pound force that can be applied by the clamp spring **536** to hold the wire, e.g., the wire strands of the stranded wire **710** against the clamp brace **532**. For example, in the example where the energy stored by the one or more springs should be sufficient to apply a constant and continuous force in the range of, for example, about 5 pound force to about 35 pound force, the higher wire retention force would be in the range of, for example, 6 pound force to about 42 pound force. In addition, the higher spring force or pressure on the wire also provides an improved electrical connection by lowering the contact resistance. Exemplary embodiments of the wire manager **900** are shown in FIGS. **43-47** and are described herein below. However, the present disclosure contemplates other wire manager embodiments where the wire manager **900** urges a wire or wire strands toward a center or middle of a clamp brace and/or a center or middle of the clamp member.

(118) As noted, the wire terminal **530** can connect to electrical conductors of different sizes. For example, if the plug **400** is rated for 15 amps, then the wire terminal **530** should also be configured and rated for at least 15 amps. The wire size, i.e., the bare conductor size, for 15 amps is 14 AWG wire such that the clamp arm **542** should be able to move to an open position where the outer diameter of 14 AWG wire can fit. As another example, if the plug **400** is rated for 20 amps, then the wire terminal **530** should also be rated for at least 20 amps. The wire size, i.e., the bare conductor size, for 20 amps is 12 AWG wire such that the clamp arm **542** should be able to move to an open position where the outer diameter of 12 AWG wire can fit. As another example, if the plug **400** is rated for 30 amps, then the wire terminal **530** should also be rated for at least 30 amps. The wire size, i.e., the bare conductor size, for 30 amps is 10 AWG wire such that the clamp arm **542** should be able to move to an open position where the outer diameter of 10 AWG wire can fit. As another example, if the plug **400** is rated for 40 amps, then the wire terminal **530** should also be rated for at least 40 amps. The wire size, i.e., the bare conductor size, for 40 amps is 8 AWG wire such that the clamp arm **542** should be able to move to an open position where the outer diameter of 8 AWG wire can fit.

(119) As noted, the spring member **540** is made of an electrically conductive resilient material with sufficient stiffness to flex when the plunger **550** pushes the spring member **540** from the closed position to the open position while applying a biasing force (i.e., a spring force) to the clamp member **546** to secure or clamp a wire between the clamp member **546** and the clamp brace **532**. As an example, the spring arm **540** can be made of metal, such as spring steel. The biasing force exerted by the spring arm **540** clamping a wire between the clamp member **546** and the clamp brace **532** should be sufficient to apply a constant and continuous force on the wire to electrically couple or connect the wire terminal **530** to the wire in various temperature and environmental conditions. The spring member **540** is configured so that it is normally biased toward the closed position, i.e., in the direction of arrow "G" which is away from the clamp brace **532**, as seen in FIG. **21**. In the spring member's **540** normal position without a conductor inserted into the elongated opening **544**, the clamp member **546** of the clamp arm **542** can contact the clamp brace **532**.

(120) As described herein, the plug **400** uses the contact assemblies **500** to terminate electrical wires within the blade-type plug. To connect wires within the plug **400**, an installer passes a wire cable through the cable receiving opening **490** in cover **480**. The insulation at the end of each wire

within the cable is then striped. In this exemplary embodiment, the plug **400** has three contact assemblies **500** such that three wires within the wire cable can be connected to the plug **400**. The portion of the plunger **550** for each contact assembly **500** extending through the retainer **460** are then pulled vertically relative to a longitudinal axis of the plug **400**, i.e., in the direction of arrow "H" seen in FIGS. **21** and **22**, to cause the camming surface **552***a* of the notch **552** in the plunger **550** to ride along the spring member **540** applying a mechanical load to the spring member **540**. Applying such mechanical load to the spring member **540** causes the spring member **540** to deflect in the direction of arrow "I" (i.e., from the closed position toward the open position). With the wire terminals **530** in the open position, the electrical wires are then inserted into the appropriate wire receiving aperture **466** in the retainer **460**. The wire receiving apertures **466** and wire guides **468** guide the bare end of the wires into the portion of the elongated opening **544** of the clamp spring **536** between clamp brace **532** and clamp member **546**. When the bare end of each wire is positioned between the clamp brace **532** and the clamp member **546**, the respective plunger **550** is then pushed back toward the main body **420** removing the mechanical load applied by the plunger **550** on the spring member **540** so that the energy stored by the spring member biases the spring member to the closed position securing the wire between the clamp brace **532** and the clamp member **546**, and completing an electrically conductive path between the wire and the contact member **510**. To remove the wires from the contact assembly **500**, the plungers **550** for each contact assembly **500** extending through the retainer **460** are pulled vertically relative to a longitudinal axis of the plug **400** to cause the camming surface **552***a* of the notch **552** in the plunger **550** to ride along the spring member **540** applying a mechanical load on the spring member **540** causing the spring member **540** to deflect from the closed position toward the open position. With the wire terminals **530** in the open position, the electrical wires can be removed from the plug **400**.

(121) Referring now to FIGS. **23-26**, an exemplary embodiment of a non-locking blade type electrical receptacle is shown. In this exemplary embodiment, the receptacle **600** has a housing **620** and a plurality of contact assemblies, which are similar to the contact assemblies **100**, described herein and shown in FIGS. **8** and **9**, within the housing that are accessible from an exterior of the housing. The housing **620** has a main body **630**, a front cover **650** and a rear cover **670**. The front cover **650** is secured to one side of the main body **630** and the rear cover **670** is secured to the other side of the main body. The housing **620** is made of a suitable electrical insulating material, such as plastic, including injection molded thermoplastic, and is configured to fit within an electrical box.

(122) The main body **630** includes a plurality of chambers or cavities **632**, seen in FIG. **26**. Each cavity **632** is configured to receive and position a contact assembly **100** within the main body **630**, as shown in FIG. **26**. Each contact assembly **100** is configured to receive a wire, such as wire **700**, and to mate with a contact blade of a conventional plug connector as described above.

(123) As shown in FIG. **23**, the front cover **650** of the receptacle **600** includes a face **652** having a plurality of blade-receiving slots **654** through which contact blades (e.g., hot, neutral and ground contact blades) of a plug connector can be inserted in the usual manner into adjacent cavities **632** within the main body **630**. The front cover **650** has one or more mounting straps **656** that are secured to an exterior surface of the front cover **650** using, for example, mechanical fasteners or adhesives. The mounting straps **656** are used to secure the receptacle **600** to an electrical box via apertures **658** as is known. The mounting straps **656** may also be connected to electrical ground via a contact assembly **100** within the main body **630**. The front cover **650** can be secured to the main body **630** using mechanical fasteners, adhesives or welds such as sonic welds.

(124) Referring to FIGS. **24** and **25**, the rear cover **670** can be secured to the main body **630** using mechanical fasteners, such as screws **672**, adhesives or welds such as sonic welds. The rear cover **670** includes a plurality of wire receiving apertures **674**. Each wire receiving aperture **674** is positioned to align with a cavity **632** in the main body **630** so that a wire can pass through the rear cover **670** into a contact assembly **100** resting within a cavity **632** in the main body **630**. The rear

cover **670** may also include a plurality of wire guides **76** extending outwardly from an exterior surface **678** of the rear cover **670**, as shown. In the embodiment shown, one wire guide **676** corresponds to one wire receiving aperture **674**. Each wire guide **676** has an arcuate shape that corresponds to the round shape of a wire being inserted into the wire receiving aperture **674**. The rear cover **670** also includes a plurality of plunger openings **680**, seen in FIG. **25**, that permits a portion of a plunger **150**, forming a portion of the contact assembly **100** described above, to extend outside the housing **620**.

(125) Referring now to FIGS. **27**-**30**, an exemplary embodiment of a switch is shown. In this exemplary embodiment, the switch **720** has a housing **740** and a plurality of contact assemblies, which are similar to the contact assemblies **100**, described herein and shown in FIGS. **8** and **9**, within the housing **740** that are accessible from an exterior of the housing **740**. However, in this embodiment, the contact assemblies **100** would not include the contact member **110** and contact arm **134**, as seen in FIGS. **31** and **32**. Instead the clamp brace **132** would connect to respective switch contacts and/or ground connections within the housing **740**.

(126) Another exemplary embodiment of a contact assembly **103** according to the present disclosure that may be used with the switch **720** is shown in FIGS. **31**A, **31**B and **32**A-**32**D. The contact assembly **103** is substantially similar to the contact assembly **100** such that like reference numerals are used to reference like components. The contact assembly **103** includes the wire terminal **130** and the plunger **150**. However, in this embodiment, the contact assemblies **103** would not include the contact member **110** and contact arm **134**. Instead, the clamp brace **132** would connect to respective switch contacts and/or ground connections within the housing **740** of the switch **720**. In addition, the wire terminal **130** would include the wire manager **900**. As described above, the clamp brace **132** has the wire manager **900** integrally or monolithically formed into the clamp brace **132**. However, the wire manager **900** may be secured to the clamp brace **132** by, for example, a solder joint, a brazed joint or a welded joint. It is to be appreciated that the wire manager **900** may also be integrally or monolithically formed into the clamp spring **136**. It is also to be appreciated that the wire manager **900** may also be secured to the clamp spring **136** by, for example, a solder joint, a brazed joint or a welded joint. The wire manager **900** is provided to cause the wire, e.g., wire **700** or the wire strands of the stranded wire **710**, to be concentrated toward a center or middle of the clamp brace **132** and/or a center or middle of the clamp member **146**. Preferably, the wire manager **900** is provided to cause wire strands of stranded wire, e.g., stranded wire **710**, to be concentrated toward a center or middle the clamp brace **132** and/or a center or middle of the clamp member **146**. Concentrating the wire, e.g., wire strands of stranded wire **710**, toward a middle the clamp brace **132** and/or a middle of the clamp member **146** increases the force or pressure applied by the clamp member **146** of the clamp arm **142** of the clamp spring **136** to the wire. For example, concentrating the wire toward a middle the clamp brace **132** and/or a middle of the clamp member **146** can increase the force or pressure applied by the clamp member **146** by, for example, about 20 percent when compared to instances where the wire, e.g., wire **710**, is not concentrated wire toward a center or middle the clamp brace **132** and/or a center or middle of the clamp member **146**. This results in a higher retention force in the range of, for example, about 1 pound force and about 7 pound force that can be applied by the clamp spring **136** to hold the wire, e.g., the wire strands of the stranded wire **710**, to the wire terminal **130**. For example, in the example where the energy stored by the one or more springs should be sufficient to apply a constant and continuous force in the range of, for example, about 5 pound force to about 35 pound force, the higher wire retention force would be in the range of, for example, 6 pound force to about 42 pound force. In addition, the higher spring force or pressure on the wire provides an improved electrical connection by lowering the contact resistance. Exemplary embodiments of the wire manager **900** are shown in FIGS. **43**-**47** and described herein below. However, the present disclosure contemplates other wire manager embodiments where the wire manager urges a wire or wire strands toward a center or middle of a clamp brace and/or a center or middle of the clamp

member.
(127) The housing **740** has a main body **750**, a front cover **770** and a rear cover **790**. The front cover **770** is secured to one side of the main body **750** and the rear cover **790** is secured to the other side of the main body **750**. The housing **740** is made of a suitable electrical insulating material, such as plastic, including injection molded thermoplastic, and is configured to fit within an electrical box. The main body **750** includes a plurality of chambers or cavities **752**, seen in **30**. Each cavity **752** is configured to receive and position a contact assembly **100** within the main body **750**, as shown in FIG. **30**. Each contact assembly **100** is configured to receive a wire, such as wire **700**, and to mate with a contact blade of a conventional plug connector as described above.
(128) As shown in FIG. **27**, the front cover **770** of the switch **720** includes a face **772** with a switch arm aperture **774** through which a conventional switch arm of a toggle switch can pass. The front cover **770** has one or more mounting straps **776** that are secured to an exterior surface of the front cover using, for example, mechanical fasteners or adhesives. The mounting straps **776** are used to secure the switch **720** to an electrical box via apertures **778** as is known. The mounting straps **776** may also be connected to electrical ground via a contact assembly **100** within the main body **750**. The front cover **770** can be secured to the main body **750** using mechanical fasteners, adhesives or welds such as sonic welds.
(129) Referring to FIGS. **28** and **29**, the rear cover **790** can be secured to the main body **750** using mechanical fasteners, adhesives or welds such as sonic welds. The rear cover **790** includes a plurality of wire receiving apertures **792**. Each wire receiving aperture **792** is positioned to align with a cavity **752** in the main body **750** so that a wire can pass through the rear cover **790** into a contact assembly **100** resting within a cavity **752** in the main body **750**. The rear cover **790** may also include a plurality of wire guides **794** extending outwardly from an exterior surface **796** of the rear cover, as shown. In the embodiment shown, one wire guide **794** corresponds to one wire receiving aperture **792**. Each wire guide **794** has an arcuate shape that corresponds to the round shape of a wire being inserted into the wire receiving aperture **792**. The rear cover **790** also includes a plurality of plunger openings **798**, seen in FIG. **29**, that permits a portion of a plunger **150**, forming a portion of the contact assembly **100** described above, to extend outside the housing **740**.
(130) Referring now to FIGS. **33-37**, an exemplary embodiment of an electrical male flanged inlet having screwless connection terminals according to the present disclosure is shown. In this exemplary embodiment, the male flanged inlet **800** has a housing **802** and a plug assembly **804**. The housing **802** may be a circular housing having a flange **806** at one end of the housing. The housing **802** is configured to be mounted into an opening in a structure, such as a wall, and the flange **806** is provided to prevent the housing **802** from passing through a properly created opening in the structure. The flange **806** may include mounting holes **808** that can be used to secure the flange **806** to the structure. The housing **802** is preferably made of a suitably rigid, electrical insulating material, such as a plastic material, or a rubber material. An example of a plastic material is injection molded thermoplastic. However, the housing **802** may be made of a metallic material.
(131) The plug assembly **804** is mounted within the housing **802** and secured to the housing using, for example, fasteners **810**. The plug assembly **804** may be similar to the blade-type plug **400** described above. For example, the plug assembly **804** may include a main body **812**, a cover **814**, a retainer **816** and a plurality of contact assemblies **501** positioned within the main body **812** and extending at least partially from an exterior of the cover **814**. As seen in FIG. **35**, the retainer **816** is secured to a top side of the main body **812** using screw **818**. The cover **814** is secured to the housing **802** by passing screws **810** through a face **820** and apertures **822** in the cover **814**, through corresponding apertures **824** in the main body **812**, and through corresponding apertures **826** in the retainer **816**. The screws **810** are then secured to corresponding mounting holes (not shown) within the housing **802**.
(132) The main body **812** includes a plurality of chambers or cavities **828**, seen in FIGS. **35** and **36**.

Each cavity **828** is configured to receive and position a contact assembly **501** within the main body **812**. Each contact assembly **501** is configured to receive a conductor and to mate with a female contact of a blade-type connector, such as the female contacts of FIG. **8** or **15**. The face **820** of the cover **814** has a plurality of blade-receiving slots **830** through which contact blades **514** of the contact assemblies **501** can be inserted so that the contact blades **514** extend outside the cover **814**. The cover **814** when secured to the housing **802** helps hold the contact assemblies **501** within the main body **812**.

(133) Referring to FIGS. **35** and **37**, the retainer **816** is secured to the main body **812** using mechanical fasteners, such as screw **818**. The retainer **816** includes a plurality of wire receiving apertures **832**. Each wire receiving aperture **832** is positioned to align with a cavity **828** in the main body **812** so that a wire can pass through the retainer **816** into a contact assembly **501** resting within the cavity **828** in the main body **812**. The retainer **816** may also include a plurality of wire guides **834** extending outwardly from surface **836** of the retainer, as shown. In the embodiment shown, one wire guide **834** corresponds to one wire receiving aperture **832**. Each wire guide **834** may have an arcuate like shape that corresponds to the shape of a wire being inserted into the wire receiving aperture **832**. The retainer **816** also includes a plurality of plunger openings **838**. In the embodiment shown, one plunger opening **838** corresponds to one wire receiving aperture **832**. The plunger openings **838** permit a portion of a respective plunger **550** forming a portion of the contact assembly **501**, described herein, to extend outside the main body **812** during installation. The contact assembly **501** is shown in FIGS. **21**A, **21**B and **22**A-**22**D and described above, and generally includes the contact member **510**, the wire terminal **530** and the plunger **550**. The wire terminal **530** includes the wire manager **900**.

(134) Referring now to FIGS. **38-42**, an exemplary embodiment of an electrical female flanged receptacle having screwless connection terminals according to the present disclosure is shown. In this exemplary embodiment, the female flanged receptacle **850** has a housing **852** and a cord connector assembly **854**. The housing **852** may be a circular housing having a flange **856** at one end of the housing. The housing **852** is configured to be mounted into an opening in a structure, such as a wall, and the flange **856** is provided to prevent the housing **852** from passing through a properly created opening in the structure. The flange **856** may include mounting holes **858** that can be used to secure the flange **856** to the structure. The housing **852** is made of a suitably rigid, electrical insulating material, such as a plastic material, including injection molded thermoplastic, or a rubber material. However, the housing **802** may be made of a metallic material.

(135) The cord connector assembly **854** is mounted within the housing **852** and secured to the housing **852** using, for example, fasteners **860**. The cord connector assembly **854** may be similar to the blade-type power cord connector **200** described above. For example, the cord connector assembly **844** may include a main body **862**, a retainer **864** and plurality of contact assemblies **301** within the main body **862** and are at least partially accessible from an exterior of the main body **862**. The retainer **864** is secured to a top side of the main body **862** using fastener **866**. The main body **862** is secured to housing **852** using the fasteners **860** inserted through apertures **868** in a face **870** in the main body **862** and through the main body **862**.

(136) The main body **862** includes a plurality of chambers or cavities **872** seen in FIGS. **40** and **41**. Each cavity **872** is configured to receive and position a contact assembly **301** within the main body **862**. Each contact assembly **301** is configured to receive a conductor and to mate with a contact blade of a blade-type plug connector, such as a contact blade of the plug connector of FIG. **17**. The face **870** of the main body **862** has a plurality of blade-receiving slots **874** through which contact blades of a blade-type plug connector can be inserted in the usual manner into adjacent cavities **872** within the main body **862** and into a respective contact assembly **301**.

(137) The retainer **864** is secured to the main body **862** using mechanical fasteners, such as screw **866**. The retainer **864** includes a plurality of wire receiving apertures **876**. Each wire receiving aperture **876** is positioned to align with a cavity **872** in the main body **862** so that a wire can pass

through the retainer **864** into a contact assembly **301** resting within a cavity **872** in the main body **862**. The retainer **864** may also include a plurality of wire guides **878** extending outwardly from surface **880** of the retainer, as shown. In the embodiment shown, one wire guide **878** corresponds to one wire receiving aperture **876**. Each wire guide **878** may have an arcuate like shape that corresponds to the shape of a wire being inserted into the wire receiving aperture **876**. The retainer **864** also includes a plurality of plunger openings **882**, seen in FIG. **42**. In the embodiment shown, one plunger opening **882** corresponds to one wire receiving aperture **876**. The plunger openings **882** permit a portion of a respective plunger **350** forming a portion of the contact assembly **301**, described herein, to extend outside the main body **862**. The contact assembly **301** is shown in FIGS. **15**A, **15**B and **16**A-**16**D and described above, and generally includes the contact member **310**, the wire terminal **330** and the plunger **350**. The wire terminal **530** includes the wire manager **900**. The retainer **864** may also include a plurality of plunger guides **884** extending outwardly from surface **886** of the retainer **864**, as shown in FIG. **40**. In the embodiment shown, one plunger guide **884** corresponds to one plunger opening **882**. The plunger guides **884** guide the plungers **350** as they are moved relative to the retainer **864**.

(138) As noted above, non-limiting and exemplary embodiments of the wire manager **900** are shown in FIGS. **43**-**47**. However, the present disclosure contemplates other wire manager embodiments where the wire manager urges a wire or wire strands to concentrate toward a center or middle of a clamp brace and/or a center or middle of the clamp member. In the exemplary wire manager embodiments shown, the wire manager **900** may be integral or monolithically formed into the clamp brace **132**, **332**, **532** or the clamp member **146**, **346**, **546**, or the wire manager **900** may be secured to the clamp brace **132**, **332**, **532** or the clamp member **146**, **346**, **546**. Each wire manager **900** may be used with the wire terminals **130**, **330**, **530** described herein.

(139) In the exemplary embodiment shown in FIG. **43**, the wire manager **900** is a V-shape like structure formed with a pair of wedges **802** and **804** joined by a rounded valley **806**. The wedges **802** and **804** may be symmetrically shaped wedges or asymmetrically shaped wedges. In the embodiment shown, the wedges **802** and **804** are symmetrically shaped wedges having a height "H" and a width "W." Preferably, the height "H" is in the range of, for example, about 0.05″ and about 0.15″, and the width "W" is in the range of, for example, about 0.1″ and about 0.2″. The wire manager **900** may extend along an entire width "W**2**" of the of the clamp brace **132**, **332**, **532**, or the wire manager **900** may extend along a portion of the width "W**2**" of the of the clamp brace **132**, **332**, **532**. In the embodiment shown, the wire manager **900** extends along the entire width "W**2**" of the of the clamp brace **132**, **332**, **532**, with the rounded valley **806** positioned at or in close proximity to a center line "C" of the clamp brace **132**, **332**, **532**. The wire manager **900** is also positioned on the clamp brace **132**, **332**, **532**, so that the wire manager **900** does not interfere with the clamp member **146**, **346**, **546** contacting the exposed conductor of the wire, e.g., the strands of the stranded wire **710**. For example, the wire manager **900** may be positioned so that the wire manager **900** is in close proximity to a contact line "C**2**," seen in FIG. **8**A, were a distal end **146***a*, **346***a*, **546***a* of the clamp member **146**, **346**, **546** would contact the clamp brace **132**, **332**, **532** when the clamp brace is in the closed position and no wire is inserted into the elongated opening **144**, **344**, **544** of the wire terminal **130**, **330**, **530**. In addition, a contact area **811** of the clamp brace **132**, **332**, **532** may include a textured surface **813** that is provided to grip the exposed wire strands or wire, e.g., the exposed wire strands of stranded wire **710**, to improve the wire retention force applied to the exposed wire strands by the clamp member **146**, **346**, **546**. The contact area **811** is at least a portion of the clamp brace **132**, **332**, **532** where the clamp member **146**, **346**, **546** would contact the clamp brace **132**, **332**, **532** when the clamp brace is in the closed position and no wire is inserted into the elongated opening **144**, **344**, **544** of the wire terminal **130**, **330**, **530**. In the embodiment of FIG. **43**, the textured surface **813** is striations.

(140) In the exemplary embodiment shown in FIG. **44**, the wire manager **900** is also a V-shape like structure formed with a pair of wedges **802** and **804**. However, in the embodiment of FIG. **44**, the

wedges **802** and **804** are joined at their narrow end forming a sharp valley **806**, as shown. The wedges **802** and **804** may be symmetrically shaped wedges or asymmetrically shaped wedges. In the embodiment shown, the wedges **802** and **804** are symmetrically shaped wedges having a height "H" and a width "W." As a non-limiting example, the height "H" may be in the range of, for example, about 0.05″ and about 0.15″, and the width "W" may be in the range of, for example, about 0.1″ and about 0.2″. The wire manager **900** may extend along an entire width "W**2**" of the of the clamp brace **132**, **332**, **532**, or the wire manager **900** may extend along a portion of the width "W**2**" of the of the clamp brace **132**, **332**, **532**. In the embodiment shown, the wire manager **900** extends along the entire width "W**2**" of the of the clamp brace **132**, **332**, **532**, with the sharp valley **806** positioned at or in close proximity to the center line "C" of the clamp brace **132**, **332**, **532**. The wire manager **900** is also positioned on the clamp brace **132**, **332**, **532**, so that the wire manager **900** does not interfere with the clamp member **146**, **346**, **546** contacting the exposed conductor of the wire, e.g., the strands of the wire **710**. For example, the wire manager **900** may be positioned so that the wire manager **900** is in close proximity to the contact line "C**2**," shown in FIG. **8**A, were the distal end **146***a*, **346***a*, **546***a* of the clamp member **146**, **346**, **546** would contact the clamp brace **132**, **332**, **532** when the clamp brace is in the closed position and no wire is inserted into the elongated opening **144**, **344**, **544** of the wire terminal **130**, **330**, **530**. In addition, a contact area **811** of the clamp brace **132**, **332**, **532** may include the textured surface **813** that is provided to grip the exposed wire strands or wire, e.g., the exposed wire strands of stranded wire **710**, to improve the wire retention force applied to the exposed wire strands by the clamp member **146**, **346**, **546**. The contact area **811** is at least a portion of the clamp brace **132**, **332**, **532** where the clamp member **146**, **346**, **546** would contact the clamp brace **132**, **332**, **532** when the clamp brace is in the closed position and no wire is inserted into the elongated opening **144**, **344**, **544** of the wire terminal **130**, **330**, **530**. In the embodiment of FIG. **44**, the textured surface **813** is knurling.

(141) In the exemplary embodiment shown in FIG. **45**, the wire manager **900** is also a V-shape like structure formed with a pair of wedges **802** and **804**. However, in the embodiment of FIG. **45**, the wedges **802** and **804** are spaced apart so that a portion of the clamp brace **132**, **332**, **532** forms the valley **806**, as shown. The wedges **802** and **804** may be symmetrically shaped wedges or asymmetrically shaped wedges. In the embodiment shown, the wedges **802** and **804** are symmetrically shaped wedges having a height "H" and a width "W." As a non-limiting example, the height "H" may be in the range of, for example, about 0.05″ and about 0.15″, and the width "W" may be in the range of, for example, about 0.1″ and about 0.2″. The wire manager **900** may extend along an entire width "W**2**" of the of the clamp brace **132**, **332**, **532**, or the wire manager **900** may extend along a portion of the width "W**2**" of the of the clamp brace **132**, **332**, **532**. In the embodiment shown, the wire manager **900** extends along a portion of the width "W**2**" of the of the clamp brace **132**, **332**, **532**, with the portion of the clamp brace forming the valley **806**. Preferably, the valley **806** is positioned at or in close proximity to a center or middle of the clamp brace **132**, **332**, **532**. The wire manager **900** is also positioned on the clamp brace **132**, **332**, **532** so that the wire manager **900** does not interfere with the clamp member **146**, **346**, **546** contacting the exposed conductor of the wire, e.g., the strands of the wire **710**. For example, the wire manager **900** may be positioned so that the wire manager **900** is in close proximity to the contact line "C**2**," shown in FIG. **8**A, where the distal end **146***a*, **346***a*, **546***a* of the clamp member **146**, **346**, **546** would contact the clamp brace **132**, **332**, **532** when the clamp brace is in the closed position and no wire is inserted into the elongated opening **144**, **344**, **544** of the wire terminal **130**, **330**, **530**. In addition, a contact area **811** of the clamp brace **132**, **332**, **532** may include the textured surface **813** that is provided to grip the exposed wire strands or wire, e.g., the exposed wire strands of stranded wire **710**, to improve the wire retention force applied to the exposed wire strands by the clamp member **146**, **346**, **546**. The contact area **811** is at least a portion of the clamp brace **132**, **332**, **532** where the clamp member **146**, **346**, **546** would contact the clamp brace **132**, **332**, **532** when the clamp brace is in the closed position and no wire is inserted into the elongated opening **144**, **344**, **544** of the wire

terminal **130**, **330**, **530**. In the embodiment of FIG. **45**, the textured surface **813** is narrow grooves.
(142) In the exemplary embodiment shown in FIG. **46**, the wire manager **900** is a U-shape like structure formed with a pair of side walls **814** and **816**, and a bottom wall **818** joined to the side walls **814** and **816** and forming a wire receiving opening or channel **820**. In the embodiment shown, the side walls **814** and **816** and bottom wall have a height "H**2**," a width "W**2**," and a length "L." As a non-limiting example, the height "H**2**" may be in the range of, for example, about 0.05″ and about 0.15″, the width "W**2**" may be in the range of, for example, about 0.1″ and about 0.2″, and the length "L" may be in the range of about 0.1″ and about 0.3″. The wire manager **900** is positioned on the clamp brace **132**, **332**, **532** so that the wire receiving opening **820** extends in a direction that is substantially parallel to a longitudinal axis of the clamp brace **132**, **332**, **532**, as shown. The wire manager **900** is also positioned on the clamp brace **132**, **332**, **532**, so that the wire manager **900** does not interfere with the clamp member **146**, **346**, **546** contacting the exposed conductor of the wire, e.g., the strands of the wire **710**. For example, the wire manager **900** may be positioned so that the wire manager **900** is in close proximity to the contact line "C**2**," shown in FIG. **8**A, where a distal end **146***a*, **346***a*, **546***a* of the clamp member **146**, **346**, **546** would contact the clamp brace **132**, **332**, **532** when the clamp brace is in the closed position and no wire is inserted into the elongated opening **144**, **344**, **544** of the wire terminal **130**, **330**, **530**. In addition, the contact area **811** of the clamp brace **132**, **332**, **532** may include the textured surface **813** that is provided to grip the exposed wire strands or wire, e.g., the exposed wire strands of stranded wire **710**, to improve the wire retention force applied to the exposed wire strands by the clamp member **146**, **346**, **546**. In this embodiment, the contact area is at least a portion of the clamp brace **132**, **332**, **532** where the exposed conductors of, for example, the stranded wire **710**, would contact the clamp brace **132**, **332**, **532** when the clamp brace is in the closed position. As described above, the textured surface may be, for example, striations, knurling and/or small grooves on the surface of the clamp brace **132**, **332**, **532**.
(143) In the exemplary embodiment shown in FIG. **47**, the wire manager **900** is an arcuate shape or C-shaped like structure having a wire receiving opening **820**. In the embodiment shown, the sides **814** and **816** and bottom have a height "H**3**," a width "W**3**," and a length "L**2**." As a non-limiting example, the height "H**3**" may be in the range of, for example, about 0.05″ and about 0.15″, the width "W**3**" may be in the range of, for example, about 0.1″ and about 0.2″, and the length "L**2**" may be in the range of, for example about 0.1″ and about 0.3″. In this exemplary embodiment, the wire manager **900** is positioned on the clamp member **146**, **346**, **546** of the clamp spring **136**, **336**, **536**, so that the wire receiving opening **820** extends in a direction that is substantially parallel to a longitudinal axis of the clamp member **146**, **346**, **546**, as shown. It is noted that the wedges **802** and **804**, and the U-shaped wire managers **900** described above, and any other suitable wire managers may be substituted for the arcuate shape or C-shaped like structure on the clamp member **146**, **346**, **546**. In addition, the contact area **811** of the clamp brace **132**, **332**, **532** may include the textured surface **813** that is provided to grip the exposed wire strands or wire, e.g., the exposed wire strands of stranded wire **710**, to improve the wire retention force applied to the exposed conductors of the wire, e.g., stranded wire **710** or wire **700**, by the clamp member **146**, **346**, **546**. In this embodiment, the contact area is at least a portion of the clamp brace **132**, **332**, **532** where the exposed conductors of, for example the stranded wire **710**, would contact the clamp brace **132**, **332**, **532** when the clamp brace is in the closed position. As described above, the textured surface may be, for example, striations, knurling and/or small grooves on the surface of the clamp brace **132**, **332**, **532**.
(144) While exemplary embodiments have been chosen to illustrate the invention, it will be understood by those skilled in the art that various changes, modifications, additions, and substitutions are possible, without departing from the scope and spirit of the invention.

Claims

1. An electrical wiring device comprising: a housing having a plurality of wire receiving apertures and a plurality of plunger openings; and a plurality of contact assemblies positioned within the housing so that each of the plurality of contact assemblies is accessible from one of the plurality of wire receiving apertures and one of the plurality of plunger openings; wherein each of the plurality of the contact assemblies includes: a wire terminal including a clamp brace secured to a clamp spring and a wire manager, the clamp spring being movable relative to the clamp brace between a closed position where a wire can be clamped between the clamp spring and the clamp brace and an open position where a wire can be inserted through one of the plurality of wire receiving apertures and between the clamp spring and the clamp brace, the wire manager being positioned on the clamp brace or the clamp spring and configured to urge the wire between the clamp spring and the clamp brace toward a center of the clamp brace or the clamp spring such that the wire is concentrated in the center of the clamp brace or the clamp spring as the wire is clamped; and a plunger positioned within the housing and extending at least partially through one of the plurality of plunger openings, the plunger being interactive with the clamp spring such that movement of the plunger in a first direction causes the plunger to apply a mechanical load to the clamp spring to cause the clamp spring to move from the closed position to the open position and movement of the plunger in a second direction that is opposite the first direction removes the mechanical load from the clamp spring so that to the clamp spring moves from the open position to the closed position.
2. The electrical wiring device according to claim 1, wherein the wire manager comprises a first wedge joined to a second wedge such that a rounded valley or a sharp valley is formed between the first wedge and the second wedge.
3. The electrical wiring device according to claim 1, wherein the wire manager comprises a first wedge, a second wedge and a valley between the first wedge and the second wedge, the valley being a portion of the clamp brace.
4. The electrical wiring device receptacle according to claim 1, wherein the wire manager comprises a first wall, a second wall and a bottom wall joined between the first wall and the second wall so that an opening is formed between the first wall and the second wall, the bottom wall being integrally formed into or attached to the clamp brace.
5. The electrical wiring device according to claim 1, wherein the wire terminal includes a clamp member configured to contact the wire positioned between the clamp spring and the clamp brace to clamp the wire between the clamp spring and the clamp brace, and wherein the wire manager extends from the clamp member.
6. The electrical wiring device according to claim 1, wherein the plunger is made of a non-conductive material.
7. The electrical wiring device according to claim 1, wherein the movement of the plunger in the second direction is opposite the movement of the plunger in the first direction.
8. The electrical wiring device according to claim 1, wherein the movement of the plunger in the first direction and the second direction is parallel to the clamp brace.
9. A screwless contact assembly for use in electrical wiring devices, the screwless contact assembly comprising: a wire terminal including a clamp brace secured to a clamp spring and a wire manager, the clamp spring being movable relative to the clamp brace between a closed position where a wire can be clamped between the clamp spring and the clamp brace and an open position where a wire can be inserted between the clamp spring and the clamp brace, the wire manager being positioned on the clamp brace or the clamp spring and configured to urge the wire between the clamp spring and the clamp brace toward a center of the clamp brace or the clamp spring such that the wire is concentrated in the center of the clamp brace or the clamp spring as the wire is clamped; and a plunger that is interactive with the clamp spring such that movement of the plunger in a first direction causes the plunger to apply a mechanical load to the clamp spring to cause the clamp spring to move from the closed position to the open position and movement of the plunger in a

second direction that is opposite the first direction removes the mechanical load from the clamp spring so that to the clamp spring moves from the open position to the closed position.
10. The screwless contact assembly according to claim 9, wherein the wire manager comprises a first wedge joined to a second wedge such that a rounded valley or a sharp valley is formed between the first wedge and the second wedge.
11. The screwless contact assembly according to claim 9, wherein the wire manager comprises a first wedge, a second wedge and a valley between the first wedge and the second wedge, the valley being a portion of the clamp brace.
12. The screwless contact assembly according to claim 9, wherein the wire manager comprises a first wall, a second wall and a bottom wall joined between the first wall and the second wall so that an opening is formed between the first wall and the second wall, the bottom wall being integrally formed into or attached to the clamp brace.
13. The screwless contact assembly according to claim 9, wherein the wire terminal includes a clamp member configured to contact the wire positioned between the clamp spring and the clamp brace to clamp the wire between the clamp spring and the clamp brace, and wherein the wire manager extends from the clamp member.
14. An electrical wiring device comprising: a housing having at least one cavity, at least one wire receiving aperture and at least one plunger opening; and at least one contact assembly positioned in the at least one cavity of the housing such that the at least one contact assembly is accessible from the at least one wire receiving aperture and the at least one plunger opening; wherein the at least one contact assembly includes: a wire terminal including a clamp brace secured to a clamp spring and a wire manager, the clamp spring being movable relative to the clamp brace between a closed position where a wire can be clamped between the clamp spring and the clamp brace and an open position where the wire can be inserted through the at least one wire receiving aperture in the housing and between the clamp spring and the clamp brace, the wire manager being positioned on the clamp brace or the clamp spring and configured to urge the wire between the clamp spring and the clamp brace toward a center of the clamp brace or the clamp spring such that the wire is concentrated in the center of the clamp brace or the clamp spring as the wire is clamped; and a plunger positioned within the at least one cavity and extending at least partially through the at least one plunger opening in the housing, the plunger being interactive with the clamp spring such that movement of the plunger in a first direction causes the plunger to apply a mechanical load to the clamp spring to cause the clamp spring to move from the closed position to the open position and movement of the plunger in a second direction that is opposite the first direction removes the mechanical load from the clamp spring so that to the clamp spring moves from the open position to the closed position.
15. The electrical wiring device according to claim 14, wherein the wire manager comprises a first wedge joined to a second wedge such that a rounded valley or a sharp valley is formed between the first wedge and the second wedge.
16. The electrical wiring device according to claim 14, wherein the wire manager comprises a first wedge, a second wedge and a valley between the first wedge and the second wedge, the valley being a portion of the clamp brace.
17. The electrical wiring device according to claim 14, wherein the wire manager comprises a first wall, a second wall and a bottom wall joined between the first wall and the second wall so that an opening is formed between the first wall and the second wall, the bottom wall being integrally formed into or attached to the clamp brace.
18. The electrical wiring device according to claim 14, wherein the wire terminal includes a clamp member configured to contact the wire positioned between the clamp spring and the clamp brace to clamp the wire between the clamp spring and the clamp brace, and wherein the wire manager extends from the clamp member.
19. The electrical wiring device according to claim 14, wherein the plunger is made of a non-

conductive material.

20. The electrical wiring device according to claim 14, wherein the movement of the plunger in the first direction and the second direction is parallel to the clamp brace.
