(57) **ABSTRACT**

Approaches presented herein provide for semantic data matching, as may be useful for selecting data from a large unlabeled dataset to train a neural network. For an object detection use case, such a process can identify images within an unlabeled set even when an object of interest represents a relatively small portion of an image or there are many other objects in the image. A query image can be processed to extract image features or feature maps from only one or more regions of interest in that image, as may correspond to objects of interest. These features are compared with images in an unlabeled dataset, with similarity scores being calculated between the features of the region(s) of interest and individual images in the unlabeled set. One or more highest scored images can be selected as training images showing objects that are semantically similar to the object in the query image.

SCALABLE SEMANTIC IMAGE RETRIEVAL WITH DEEP TEMPLATE MATCHING

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to U.S. patent application Ser. No. 17/226,584, filed Apr. 9, 2021, and entitled "Scalable Semantic Image Retrieval in the Wild With Deep Template Matching," which claims priority to U.S. Provisional Patent Application Ser. No. 63/111,559, filed Nov. 9, 2020, and entitled "Scalable Semantic Image Retrieval in the Wild With Deep Template Matching," which are hereby incorporated herein in their entirety and for all purposes.

BACKGROUND

[0002] Retrieving images including objects that are semantically similar has many practical use cases. One such use case involves the selection of images for use in training a neural network for a task such as object detection. Automatic dataset mining can involve the determination of relevant data from a large-scale pool of unlabeled data. Manual mining at such a large scale may be infeasible, if not at least impractical. Further, the objects of interest in these images may not always be in ideal positions, orientations, or under optimal circumstances for certain training tasks. For example, the objects of interest may be (undesirably) small relative to the size of the images, may be at least partially occluded, or may be represented along with many other objects of similar or different types in these images. Existing semantic image retrieval methods often focus on mining for larger geographical landmarks, or require extra labeled data, such as images or image pairs with similar objects, for mining images with generic objects, and are not well suited for such tasks.

BRIEF DESCRIPTION OF THE DRAWINGS

[0003] Various embodiments in accordance with the present disclosure will be described with reference to the drawings, in which:

[0004] FIG. **1** illustrates image data that can be utilized in a semantic matching process, according to at least one embodiment;

[0005] FIG. **2** illustrate an image mining system, according to at least one embodiment;

[0006] FIG. **3** illustrates components of a semantic matching system, according to at least one embodiment;

[0007] FIG. **4** illustrates a patch wise matching process, according to at least one embodiment;

[0008] FIG. **5** illustrates a process for locating one or more semantically similar images from an unlabeled dataset, according to at least one embodiment;

[0009] FIG. **6** illustrates components of a system for performing semantic feature matching, according to at least one embodiment;

[0010] FIG. **7**A illustrates inference and/or training logic, according to at least one embodiment;

[0011] FIG. **7**B illustrates inference and/or training logic, according to at least one embodiment;

[0012] FIG. **8** illustrates an example data center system, according to at least one embodiment;

[0013] FIG. **9** illustrates a computer system, according to at least one embodiment;

[0014] FIG. **10** illustrates a computer system, according to at least one embodiment;

[0015] FIG. **11** illustrates at least portions of a graphics processor, according to one or more embodiments;

[0016] FIG. **12** illustrates at least portions of a graphics processor, according to one or more embodiments;

[0017] FIG. **13** is an example data flow diagram for an advanced computing pipeline, in accordance with at least one embodiment;

[0018] FIG. **14** is a system diagram for an example system for training, adapting, instantiating and deploying machine learning models in an advanced computing pipeline, in accordance with at least one embodiment; and

[0019] FIGS. **15**A and **15**B illustrate a data flow diagram for a process to train a machine learning model, as well as client-server architecture to enhance annotation tools with pre-trained annotation models, in accordance with at least one embodiment.

DETAILED DESCRIPTION

[0020] Approaches in accordance with various embodiments can provide for the automated identification or retrieval of images from an unlabeled dataset. In particular, various embodiments can utilize a semantic feature-based approach to identify images, from a large unlabeled dataset, that include representations of one or more objects that are semantically similar to one or more objects in a query image. In order to improve the accuracy of such a process, the features from a query image to be used for matching can include only those that correspond to specific regions of interest within the query image, where a region of interest can correspond to a portion of the query image in which a representation of an object of interest is located. This can enable accurate matching even in scenarios or under conditions that are traditionally challenging for semantic image retrieval approaches, such as (without limitation): when an object of interest represents only a relatively small portion of a query image, is one of a number of objects in the query image, or is at least partially obscured, among other such options. Such a scalable semantic image retrieval process can be used for various purposes, such as to automatically mine unlabeled data sets for training images useful for training and testing deep neural networks (DNNs).

[0021] FIG. **1** illustrates an example set of image data that can be utilized in a semantic image retrieval process in accordance with various embodiments. A labeled data set may be deficient for any of a number of reasons, such as (for example and without limitation): not including a sufficient number or variety of objects of a given class of object to be recognized. Accordingly, it can be desirable to attempt to automatically identify and label other images that include representations of those objects and thus can be included in the data set. As mentioned, however, such a task can be challenging to perform accurately without manual intervention using conventional approaches. In this example, a query image **100** can be selected or determined that may include one or more objects of interest. These objects may include, for example, vehicles **102** or pedestrians **104** that are to be identified by a neural network used for a task such as autonomous vehicle navigation. In at least one embodiment, this query image **100** may be processed with an object detector to identify representations of these objects of interest. The output of this object detector may include a set of image features for the query image, as well as one or more

bounding boxes, or other identification mechanisms, identifying portions of the query image **100** that correspond to respective objects of interest. For discussion purposes, the portions of the query image located inside these bounding boxes, or identification mechanisms, will be referred to as regions of interest (ROIs), which each include an identified object of interest (OOI). Objects of interest may include any objects of one or more classes, categories, or types that may be identified based at least in part upon representative visual features that may be representable in an image. The objects may be considered to be "of interest" at least for the desire to identify those types of objects in image (or other) data, such as for any of a number of various object recognition-based tasks.

[0022] Conventional feature-based image matching techniques typically compare all features of a query image against a set of target images. While this can produce acceptable results, such a process can miss several images that represent various objects of interest. For example, consider query image **100**, which contains many buildings in an urban location, with multiple vehicles and pedestrians. A conventional image matching process might only identify other images that also include multiple vehicles and pedestrians in an urban environment, which would provide for a high feature match score based on features of the entire query image. Further, if the features from the entire query image are used then the larger objects (at least as represented in the image) will dominate, as they occupy more image area and will generally have a higher number of image features. It may be desirable, however, to identify images that include various objects of interest in other settings, different poses, different locations in the images (e.g., in different traffic lanes), or in different settings or scenes (e.g., urban or highway settings), as well as under different illumination conditions (e.g., day or night) or other such aspects. For example, consider matching image **140**. This image includes a couple vehicles, but does not contain representations of pedestrians and is not located in an urban environment. Therefore, this image may not get picked up in a conventional matching process due to not sufficiently matching the entire query image **100**.

[0023] Approaches in accordance with various embodiments, however, can utilize features of one or more individual regions of interest within an image to perform semantic matching. According to various embodiments, a region of interest will occupy only a portion of the overall image, and may occupy only a small portion of that image area with only a few features, which avoids the problem that can result in conventional techniques when using features of an entire image where larger objects will dominate, since they occupy more image area and will have a higher number of features. For example, an example region of interest **120** from the query image can include a representation of a type of vehicle. If only features from this region of interest **120** are used for matching, then matching image **140** may be identified as a match since there is at least one region in the image with an object **142** that is semantically similar to the object in the region of interest. Even though an overall match score between the two images **100**, **140** may be low, there can be a high match score generated between the matching image **140** and the region of interest **120**. Such an approach can help to identify matching images even when every other aspect of the matching image may be different than the query image.

[0024] Similarly, such an approach can help to identify matching images even when an object of interest is only one of a number of objects in an image, or occupies only a small portion of the image. Consider region of interest **160**, which corresponds to a pedestrian in the query image **100**. The pedestrian may make up a small portion of the query image, such as less than 5% of the image area in this example. A pedestrian **182** represented in a matching image **180** may occupy an even smaller percentage. Using a conventional matching approach, this matching image **180** may not be identified due to the small portion of the images that match based on the object. Using features only of a region of interest **160** for matching, however, allows for an accurate match to the pedestrian **182** in the matching image **180** even though it is only one of a number of objects in the matching image and occupies only a small portion of the image. Such an approach can thus provide for much more accurate object identification and image selection than prior approaches. Further, since such an approach can still use identified image features, but use only a subset of the overall image features, such additional accuracy does not come with significant additional complexity or processing capacity requirements.

[0025] Approaches in accordance with various embodiments can utilize one or more algorithms, such as a fast and robust template matching algorithm that can be utilized in a deep neural network (DNN) feature space. Such an approach can retrieve semantically-similar images, at the object level, from a large unlabeled pool of data. In at least one embodiment, the regions around one or more objects of interest in a query image can be determined and projected onto the DNN feature space for use as a matching template. Such an approach enables focusing on the semantics of the objects of interest without the need for extra labeled data. Such an approach can be utilized in the context of dataset mining for fixing failure cases in object detection DNNs, such as may be used for autonomous vehicle (AV) navigation. Such an approach can also provide for high recall in mining for images with small-sized objects of interest, and can be used to retrieve images with one or more semantically different co-occurring objects of interest.

[0026] In at least one embodiment, an object retrieval process can locate images with objects that are semantically similar to one or more objects of interest in a query image. Such a fundamental computer vision task has many practical applications, as may include geographical landmark recognition. As mentioned, such a process can also be used for automatic mining of datasets at an object-level for fixing failure cases, such as false negatives or positives in production-level object detection deep neural networks (DNNs). These failure cases occur across different scenarios and conditions, and are often due to an under-representation of such data in the training dataset. An automatic dataset mining task for fixing autonomous vehicle object detection DNN failures, for example, can involve automatically finding the relevant data with objects that are semantically similar to the objects of interest in the failure cases from a large-scale pool of unlabeled data. FIG. **2** illustrates an example mining system **200** that can be utilized for such a task. In this example, a set of labeled training data **202** including identified objects of interest can be provided as training data to a deep neural network **204**. The output can be a set of labeled test data **206** with features and regions of interest identified. In at least one embodiment, a trained object detector can be used to extract feature maps at certain

layers. Some amount of processing may be performed on these feature maps, such as to reduce noise or remove excess data, and these maps can then be used as representations of the content of an image at a semantic level.

[0027] From this labeled dataset, a set of query images **208** can be selected with these identified regions of interest. The query images **208** can then be passed to an automatic mining task **212**, as may be implemented using a respective system, service, device, application, or process, which may also include or utilize at least one neural network. Features from the regions of interest can then be used during automatic mining to perform semantic matching against images in an unlabeled data source **210**, such as a repository or library of images, video, or other such content. Semantic features can also be extracted from the unlabeled data for semantic matching. To extract this embedding, individual frames can be processed using a forward pass through a pre-trained DNN, wherein an embedding or feature map is extracted that characterizes the content of that image at a semantic level. The mining task can identify images that have portions or feature maps that semantically match features of one or more regions of interest, or feature templates, such as with at least a minimum confidence or match score, and these semantically similar images **214** can then be added to the labeled training data set **202** for further training and testing of the neural network **204**.

[0028] As mentioned, such an automatic dataset mining task can be formulated as a semantic image retrieval problem which takes as input a small set of query images (e.g., a few tens of query images) with annotations, such as bounding box annotations, associated with one or more objects of interest in the scene. This task can then locate images from a large pool of unlabeled data that include representations of semantically similar objects. These annotations can form regions of interest (ROIs) in the query images. These ROIs can correspond to objects which a neural network, such as a production-level DNN for autonomous vehicles, systematically failed to detect. For such a DNN, this may include failures to detect motorcycles at night, bicycles mounted on cars, and so on. The ROI can be used as a template for searching functions, with deep features used to represent the template and image search space through a deep template matching (DTM) process.

[0029] In at least one embodiment, a DTM process can utilize a fast and robust template-matching algorithm in the DNN feature space that retrieves semantically similar images at the object-level from a large unlabeled pool of data. This can be solved by projecting the region(s) around the objects of interest in the query image to the DNN feature space for use as a template. In at least one embodiment, a linear time one shot similarity score can be computed in the deep feature space. Such a computation can be relatively inexpensive, even on large data sets, and can provide flexibility for retrieving multiple semantically-similar objects without increasing computational complexity. A DTM process can provide high accuracy, including an ability to provide high recall values for queries with one or more objects of interest, or templates, of any size and multiple semantic categories in real-world scenes that may include occlusions or heavy clutter. Such a process can also provide computational efficiency, such as quick mining time on a graphics processing unit (GPU), which can be important for fast experimental turnaround time in at least some production-level pipelines. In at least some embodiments, a DTM process can also precompute the image embeddings in DNN feature space offline, which can help to increase a speed of score determination. The computational complexity of DTM does not depend on the number or semantic category of the object(s) of interest in the query image. DTM can seamlessly locate multiple objects of one or more semantic categories co-occurring in a given sample image. An example DTM process can also provide for multi-template search in one shot. This can include, for example, mining using multiple failures and multiple objects of interest belonging to different semantic categories, which can be performed seamlessly, and in one shot, for the same computational complexity as a single object of interest.

[0030] In at least one embodiment, a DTM process can successfully locate or identify images with semantically similar objects, even when the objects of interest in the query image are quite small in size (e.g., occupy less than about 0.3% of area in an input 2MP image), as well as where there may be one or more occlusions or heavy scene clutter with multiple kinds of other objects. This might be the case, for example, with images of busy streets with many cars and pedestrians in the query and unlabeled pool of images. Conventional methods to solve such a problem are either computationally expensive, manually intensive, or require additional labeled training data. Alternatively, a DTM process can be computationally cheap, can work seamlessly for multiple co-occurring objects of the same or different semantic category, and does not require additional labeled training data.

[0031] FIG. **3** illustrates an example end-to-end architecture **300** that can be used for a DTM process in accordance with at least one embodiment. This example system can take, as input, a query image I_Q **302** with a bounding box around each of one or more objects of interest, where each bounding box can define a respective region of interest (ROI). The system **300** can also accept as input a set A of unlabeled sample images. In this example, I_Q can represent the ROI in the query image. A goal in at least one embodiment is to locate one or more images I_S from the set A of unlabeled images which have regions semantically similar to the region of interest I_Q. For simplicity, I_Q can be assumed to be a single query image **304** with a single ROI I_Q, with Is being a single sample image. From this input, features can be extracted including F_Q, $F_S \in R^{wxhxc}$ for I_Q and I_S respectively, using a pre-trained object detector DNN **306**. In this example, the dimensions are denoted as w: width, h: height and c: number of channels. I_Q can then be projected onto F_Q to obtain $F'_Q \in R^{wxhxc}$. In at least one embodiment, this can be accomplished by linearly projecting the ROI I'_Q onto F_Q and zeroing out features that do not have a one-to-one correspondence with I_Q. It can be noted that F_Q can be a final representation of the template that is used to compute similarity with all $F_S \in A$ (features of the unlabeled dataset). Before using these features for computing similarity, the features can be L2 normalized along the channel dimension c, which can have various benefits as discussed elsewhere herein.

[0032] The template **308** from the query image **302** can then be used with the feature map **310** of the sample image to generate a similarity matrix S **312**. This similarity matrix **312** can then be used to generate a similarity score **314** between the query template **308** and the sample image feature map **310**. FIG. **4** illustrates a view of a patch wise similarity score determination process **400** that can be used

for such purposes. Feature tensors F_Q and F_S can be considered, where each spatial location is denoted by $F'_Q[i, j]$ and $F_S[x, y]$ respectively, as illustrated in FIG. **4**, which are generated from a query image patch **402** and sample image patch **404**, respectively. These tensors can be defined to be tensors of depth c as a patch since they map to a certain region (e.g., patch) in the original image. Hence, both F'_Q and F_S have w*h patch wise feature vectors, each of length c. Patch wise cosine similarity scores **408** can then be calculated between F'_Q and F_S by, for example, computing the similarity between F'_Q [i, j] and $F_S[x, y]$ for all values of x,i∈[0,w−1] and y,j∈[0,h−1]. It can be noted that F'_Q [i, j], $F_S[x, y] \in R^{1xc}$. The similarity score between the zeroed patches in F_Q and F_S need not be computed as this does not affect the final score.

[0033] In at least one embodiment, a goal is to find the score of the best matching sample patch feature for each query patch feature F'_Q [i, j], at spatial location (i, j). To compute this score, a cosine similarity algorithm can be used due at least in part to its computational efficiency. In at least one embodiment, a score can be calculated between every patch in the query image and every patch in the sample image, and the cosine similarity computed along the channel dimension. This results in a four dimensional patch wise cosine similarity tensor $S \in R^{wxhwxh}$ which can be given by:

$$Sim(F_S, F_{Q'})[x, y, i, j] = \frac{F_S[x, y] \cdot F_{Q'}[i, j]}{|F_S[x, y]|_2 |F_{Q'}[i, j]|_2}$$

A larger $Sim(F_S, F_{Q'})$ [x, y, i, j] value indicates that sample patch feature $F_S[x, y]$ and query patch feature $F_Q[i, j]$ are more similar to each other. It can be noted that the tensor S[x, y,:,:] stores similarity scores between sample patch feature F_S [x, y] and all query patch features, and S[:,:, i, j] stores similarity scores between query patch feature $F_Q[i, j]$ and all sample patch features.

[0034] Computing S can be highly efficient for at least a couple different reasons. For example, both $F_{Q'}$ and F_S can be L2 normalized such that:

$$|F_S[x, y]|_2 \cdot |F_{Q'}[i, j]|_2 = 1$$

Hence, the cosine similarity can boil down to computing a dot product along the channel dimension, which can be highly parallelizable on the processor (e.g., GPU and/or CPU) using off the shelf operations, such as tf.tensordot or np.tensordot. Further, F'_Q in this example has all zeroes except the ROI which makes it sparse, thereby enabling advantages of sparse matric multiplications. It can also be noted that since F'_Q and F_S are L2 normalized, both Euclidean and cosine similarity can lead to same (or similar) ranking of the patch wise feature scores. In at least one embodiment, cosine similarity can be utilized due at least to its computation efficiency as explained above.

[0035] In at least one embodiment, score maps may be computed by averaging over these best matched cosine similarity scores. This can result in two score maps M_S and $M_{Q'}$ which can be computed as follows:

$$M_S = \max(S, \text{axis} = (2, 3))$$

$$M_{Q'} = \max(S, \text{axis} = (0, 1))$$

[0036] Each element of $M_S[x, y]$ indicates the best matching score found between the patch feature $F_S[x, y]$ and any patch feature in F'_Q. Similarly, each element of $M'_Q[i, j]$ indicates the best matching score found between the patch feature $F'_Q[i, j]$ and any patch feature in F_S. The final score between S and Q can be computed in at least three ways, as may be given by:

$$\text{Score}(S, Q) = \text{Mean}(M_{Q'})$$

$$\text{Score}(S, Q) = \text{Mean}(M_S)$$

$$\text{Score}(S, Q) = \frac{\text{Mean}(M_S) + \text{Mean}(M_{Q'})}{2}$$

Note that the final score will be biased towards larger ROI, especially for cases where the query image template has multiple objects of different sizes and semantic categories. To counter this, the final score map ROI regions corresponding to each of the queries can be further normalized by the area of the ROI in the feature map.

[0037] In order to compute the score of the best matching sample patch feature for each query patch feature, a max function can be used over the cosine similarity scores stored in S. This gives a score map $M'_Q \in R^{wxh}$ which may be given by:

$$M'_Q = \frac{\max_{axis=(0,1)} S(F_S, F'_Q)}{A'_Q}$$

where $A'_Q \in R^{wxh}$ is a normalization constant that is proportional to the area of the projected ROI(s) at each spatial location in the feature space F'_Q. M'_Q can be biased towards objects with larger ROIs in cases where the query image template has multiple ROIs with objects of different sizes occupying different ROI areas. This can be countered with the normalization constant A'_Q. Each element of M'_Q [i, j], where i∈[0, w−1] and j∈[0, h−1], indicates the best matching score found between the patch feature F'_Q [i, j] and any patch feature in F_S, normalized by the area of the ROI at spatial location (i, j), which is denoted by $A'_Q[i, j]$.

[0038] Using the score map M'_Q, a final score can be computed between query image I_Q and sample image I_S by averaging over the best patch wise similarity scores, as may be given in at least one embodiment by:

$$\text{Score}(I_Q, I_S) = \text{Mean}(M'_Q)$$

while other score definitions can be used as well as discussed and suggested elsewhere herein. It can be noted that in Score (I_Q, I_S), spatial relationships across features within the template are not exploited. Computing scores that exploit spatial relationships explicitly tend to have higher runtime complexity while not yielding significant retrieval recall

gains based on our empirical experimentation. Score map M'_Q can accurately match the semantics of the region of interest in the query image to the object in the sample image.

[0039] In one example, an internal research dataset was used with 465 k labeled images and another dataset with 2.2 M unlabeled night-time images. A small initial set of 36 representative query images was selected, where the ROI in each query image corresponds to a motorcycle. These query motorcycles are chosen to have diverse characteristics such as pose, size, orientation, lane location, and headlights (on/off). For fairness, disjoint driving sessions of the dataset and the query images was ensured. A one-stage object detector was used that is based on a UNet-backbone, pre-trained on a 900 k labeled dataset to detect the classes: 'car', 'truck', 'pedestrian', 'bicycle' and 'motorcycle'. The object detector is trained to generalize over diverse scenarios that vary in lighting (day and night), weather conditions, illumination, occlusion and camera distance, as non-limiting examples. In this example, an image is represented by extracting features $F \in R^{wxhxc}$ from the penultimate layer of this pre-trained object detector DNN. To reduce storage costs, the embedding was downsized by adding a maxpool layer. For comparison with a baseline approach, an image can be represented by flattening F using global average pooling such that $F \in R^{xC}$.

[0040] In this set of experiments an example DTM approach was evaluated and compared with other baseline methodologies. The task is to find semantically similar motorcycles in a labeled dataset with 465 k images that were a part of the training data for the object detection model. This dataset has 10.28% images with at least one motorcycle, which is used as an upper bound for random selection. The experiment evaluated both the methods using Top-N recall where a mined image is counted as a true positive if it has at least one motorcycle. In this example, DTM outperformed the baseline and random matching approaches by a significant margin, with good recall across the entire range of the query ROI area. The recall for the baseline approach degrades significantly for ≤5% ROI area. DTM avoids such degradation by performing a patch wise similarity only using the ROI area from the query image. The example DTM approach produces sharp and localized heatmaps denoting its ability to accurately mine semantically similar objects. Since the baseline method uses a globally averaged flat embedding it cannot focus on the ROI. Evaluations on unlabeled data provided similarly strong results.

[0041] As mentioned, such an approach can be extended to accommodate queries with multiple regions of interest at no extra computation cost. This can be done in at least one embodiment by projecting all the ROIs in the query image onto the query feature map as discussed above. The score maps can be normalized using the area of each object so that the retrieved images are not biased towards larger objects. For an autonomous vehicle application, the performance of DTM can be evaluated for retrieving semantically similar images with a motorcycle and a bicycle.

[0042] FIG. **5** illustrates an example process **500** for performing deep template matching that can be utilized in accordance with various embodiments. It should be understood that for this and other processes presented herein that there can be additional, fewer, or alternative steps performed in similar or alternative orders, or at least partially in parallel, within the scope of the various embodiments unless otherwise specifically stated. Further, while image data is used as an example it should be understood that other types of data can be used with such a process as well, as discussed and suggested elsewhere herein. In this example, a query image is selected **502** from a set of labeled data, such as a set of training images to be used to train and test a neural network. The selected query image as labeled includes a representation of at least one object of interest, such as an object of an identified class (e.g., vehicle or person). A set of semantic features (or embedding vectors, etc.) can be extracted **504**, or otherwise determined, for the query image. This can include identifying semantic features in one or more regions of interest in the query image that include representations of one or more objects of interest. The features from each such region of interest can be used to generate a respective feature template. The regions of interest may represent a small portion of the overall image size, and there may be multiple regions of interest in a given query image. In some embodiments, a subset of these regions may be utilized for matching.

[0043] The feature template(s) can then be compared **506** against a plurality of images contained within a set of unlabeled data, which may include a very large collection of images. The template(s) can be compared against semantic features extracted from the plurality of images. As part of the comparison, patch wise similarity scores can be calculated **508** for individual images with respect to individual matching templates. As mentioned, these can be cosine or Euclidian similarity scores, among other such options. One or more of these unlabeled images can be selected **510** as including a representation of at least one object of interest, based at least in part upon these calculated similarity scores. There may be multiple similarity scores calculated for an unlabeled image with respect to various templates, and an image may be selected based upon a highest such similarity score. The selection may be based upon a number of highest scored images, images with a similarity score above a similarity threshold, or another such approach. Selected images having representations of one or more objects of interest can then be added **512** to the set of labeled data, such as for use in training and testing a neural network. This can help to identify objects that may be relatively small in an image or located in images with other objects, such as bikes on the backs or tops of vehicles in urban scenes.

[0044] As mentioned, such a process an provide for accurate semantic object retrieval in the wild by using deep features. This can be utilized in the context of automatic dataset mining at an object-level for fixing failures, such as false negatives and positives, in a DNN-based object detector. These failure cases typically have unusual characteristics in terms of scale, pose, occlusion and tend to be absent or under-represented in the DNN training dataset. Fixing these failure cases often involves mining for semantically similar objects from a large pool of unlabeled data. A method as presented in FIG. **5**, however, can focus on the semantics of the objects of interest by projecting them onto the DNN feature space, and can have high recall even when the object is small-sized, amid occlusion and heavy scene clutter. Such a method can also work seamlessly for multiple co-occurring objects in one or more semantic categories for object-level retrieval. Unlike other methods, it does not require extra labeled training data. Such a method can utilize a fast and robust dot-product based template matching procedure for automatic data mining.

[0045] As an example, FIG. **6** illustrates an example network configuration **600** that can be used to provide or generate content. In at least one embodiment, a client device **602** can generate content for a session using components of a content application **604** on client device **602** and data stored locally on that client device. In at least one embodiment, a content application **624** (e.g., an image generation or editing application) executing on content server **620** (e.g., a cloud server or edge server) may initiate a session associated with at least client device **602**, as may utilize a session manager and user data stored in a user database **634**, and can cause content **632** to be determined by a content manager **626** and rendered using a rendering engine, if needed for this type of content or platform, and transmitted to client device **602** using an appropriate transmission manager **622** to send by download, streaming, or another such transmission channel. The content server **620** can also include one or more training modules **630** for training a component, network, or pipeline. The server **620** may include a matching component **628** for identifying additional data to be used in training or testing that network. In at least one embodiment, client device **602** receiving this content can provide this content to a corresponding content application **604**, which provide at least some of this content for presentation via client device **602**, such as image or video content through a display **606** and audio, such as sounds and music, through at least one audio playback device **608**, such as speakers or headphones. For live video content captured by one or more cameras, for example, such a rendering engine may not be needed, unless used to augment that video content in some way.

[0046] In at least one embodiment, at least some of this content may already be stored on, rendered on, or accessible to client device **602** such that transmission over network **640** is not required for at least that portion of content, such as where that content may have been previously downloaded or stored locally on a hard drive or optical disk. In at least one embodiment, a transmission mechanism such as data streaming can be used to transfer this content from server **620**, or content database **634**, to client device **602**. In at least one embodiment, at least a portion of this content can be obtained or streamed from another source, such as a third party content service **660** that may also include a content application **662** for generating or providing content. In at least one embodiment, portions of this functionality can be performed using multiple computing devices, or multiple processors within one or more computing devices, such as may include a combination of CPUs and GPUs.

[0047] In at least one embodiment, content application **624** includes a content manager **626** that can determine or analyze content before this content is transmitted to client device **602**. In at least one embodiment, content manager **626** can also include, or work with, other components that are able to generate, modify, or enhance content to be provided. In at least one embodiment, this can include a rendering engine for rendering image or video content. In at least one embodiment, an image, video, or scene graph generation component **628** can be used to generate a scene graph, which can be used by the content application **624** on the server or the content application **604** on the client device to generate image, video, or other media content. In at least one embodiment, an enhancement component **630**, which can also include a neural network, can perform one or more enhancements on this content, as discussed and suggested herein. In at least one embodiment, content manager **626** can cause this content to be transmitted to client device **602**. In at least one embodiment, a content application **604** on client device **602** may also include components such as a template matching process **612**, or content generation module, such that any or all of this functionality can additionally, or alternatively, be performed on client device **602**. In at least one embodiment, a content application **662** on a third party content service system **660** can also include such functionality. In at least one embodiment, locations where at least some of this functionality is performed may be configurable, or may depend upon factors such as a type of client device **602** or availability of a network connection with appropriate bandwidth, among other such factors. In at least one embodiment, a system for content generation can include any appropriate combination of hardware and software in one or more locations. In at least one embodiment, generated image or video content of one or more resolutions can also be provided, or made available, to other client devices **650**, such as for download or streaming from a media source storing a copy of that image or video content. In at least one embodiment, this may include transmitting images of game content for a multiplayer game, where different client devices may display that content at different resolutions, including one or more super-resolutions.

[0048] In this example, these client devices can include any appropriate computing devices, as may include a desktop computer, notebook computer, set-top box, streaming device, gaming console, smartphone, tablet computer, VR headset, AR goggles, wearable computer, or a smart television. Each client device can submit a request across at least one wired or wireless network, as may include the Internet, an Ethernet, a local area network (LAN), or a cellular network, among other such options. In this example, these requests can be submitted to an address associated with a cloud provider, who may operate or control one or more electronic resources in a cloud provider environment, such as may include a data center or server farm. In at least one embodiment, the request may be received or processed by at least one edge server, that sits on a network edge and is outside at least one security layer associated with the cloud provider environment. In this way, latency can be reduced by enabling the client devices to interact with servers that are in closer proximity, while also improving security of resources in the cloud provider environment.

[0049] In at least one embodiment, such a system can be used for performing graphical rendering operations. In other embodiments, such a system can be used for other purposes, such as for providing image or video content to test or validate autonomous machine applications, or for performing deep learning operations. In at least one embodiment, such a system can be implemented using an edge device, or may incorporate one or more Virtual Machines (VMs). In at least one embodiment, such a system can be implemented at least partially in a data center or at least partially using cloud computing resources.

Inference and Training Logic

[0050] FIG. **7**A illustrates inference and/or training logic **715** used to perform inferencing and/or training operations associated with one or more embodiments. Details regarding inference and/or training logic **715** are provided below in conjunction with FIGS. **7**A and/or **7**B.

[0051] In at least one embodiment, inference and/or training logic **715** may include, without limitation, code and/or

data storage **701** to store forward and/or output weight and/or input/output data, and/or other parameters to configure neurons or layers of a neural network trained and/or used for inferencing in aspects of one or more embodiments. In at least one embodiment, training logic **715** may include, or be coupled to code and/or data storage **701** to store graph code or other software to control timing and/or order, in which weight and/or other parameter information is to be loaded to configure, logic, including integer and/or floating point units (collectively, arithmetic logic units (ALUs). In at least one embodiment, code, such as graph code, loads weight or other parameter information into processor ALUs based on an architecture of a neural network to which the code corresponds. In at least one embodiment, code and/or data storage **701** stores weight parameters and/or input/output data of each layer of a neural network trained or used in conjunction with one or more embodiments during forward propagation of input/output data and/or weight parameters during training and/or inferencing using aspects of one or more embodiments. In at least one embodiment, any portion of code and/or data storage **701** may be included with other on-chip or off-chip data storage, including a processor's L1, L2, or L3 cache or system memory.

[0052] In at least one embodiment, any portion of code and/or data storage **701** may be internal or external to one or more processors or other hardware logic devices or circuits. In at least one embodiment, code and/or code and/or data storage **701** may be cache memory, dynamic randomly addressable memory ("DRAM"), static randomly addressable memory ("SRAM"), non-volatile memory (e.g., Flash memory), or other storage. In at least one embodiment, choice of whether code and/or code and/or data storage **701** is internal or external to a processor, for example, or comprised of DRAM, SRAM, Flash or some other storage type may depend on available storage on-chip versus off-chip, latency requirements of training and/or inferencing functions being performed, batch size of data used in inferencing and/or training of a neural network, or some combination of these factors.

[0053] In at least one embodiment, inference and/or training logic **715** may include, without limitation, a code and/or data storage **705** to store backward and/or output weight and/or input/output data corresponding to neurons or layers of a neural network trained and/or used for inferencing in aspects of one or more embodiments. In at least one embodiment, code and/or data storage **705** stores weight parameters and/or input/output data of each layer of a neural network trained or used in conjunction with one or more embodiments during backward propagation of input/output data and/or weight parameters during training and/or inferencing using aspects of one or more embodiments. In at least one embodiment, training logic **715** may include, or be coupled to code and/or data storage **705** to store graph code or other software to control timing and/or order, in which weight and/or other parameter information is to be loaded to configure, logic, including integer and/or floating point units (collectively, arithmetic logic units (ALUs). In at least one embodiment, code, such as graph code, loads weight or other parameter information into processor ALUs based on an architecture of a neural network to which the code corresponds. In at least one embodiment, any portion of code and/or data storage **705** may be included with other on-chip or off-chip data storage, including a processor's L1, L2, or L3 cache or system memory. In at least one embodiment, any portion of code and/or data storage **705** may be internal or external to on one or more processors or other hardware logic devices or circuits. In at least one embodiment, code and/or data storage **705** may be cache memory, DRAM, SRAM, non-volatile memory (e.g., Flash memory), or other storage. In at least one embodiment, choice of whether code and/or data storage **705** is internal or external to a processor, for example, or comprised of DRAM, SRAM, Flash or some other storage type may depend on available storage on-chip versus off-chip, latency requirements of training and/or inferencing functions being performed, batch size of data used in inferencing and/or training of a neural network, or some combination of these factors.

[0054] In at least one embodiment, code and/or data storage **701** and code and/or data storage **705** may be separate storage structures. In at least one embodiment, code and/or data storage **701** and code and/or data storage **705** may be same storage structure. In at least one embodiment, code and/or data storage **701** and code and/or data storage **705** may be partially same storage structure and partially separate storage structures. In at least one embodiment, any portion of code and/or data storage **701**and code and/or data storage **705** may be included with other on-chip or off-chip data storage, including a processor's L1, L2, or L3 cache or system memory.

[0055] In at least one embodiment, inference and/or training logic **715** may include, without limitation, one or more arithmetic logic unit(s) ("ALU(s)") **710**, including integer and/or floating point units, to perform logical and/or mathematical operations based, at least in part on, or indicated by, training and/or inference code (e.g., graph code), a result of which may produce activations (e.g., output values from layers or neurons within a neural network) stored in an activation storage **720** that are functions of input/output and/or weight parameter data stored in code and/or data storage **701** and/or code and/or data storage **705**. In at least one embodiment, activations stored in activation storage **720** are generated according to linear algebraic and or matrix-based mathematics performed by ALU(s) **710** in response to performing instructions or other code, wherein weight values stored in code and/or data storage **705** and/or code and/or data storage **701** are used as operands along with other values, such as bias values, gradient information, momentum values, or other parameters or hyperparameters, any or all of which may be stored in code and/or data storage **705** or code and/or data storage **701** or another storage on or off-chip.

[0056] In at least one embodiment, ALU(s) **710** are included within one or more processors or other hardware logic devices or circuits, whereas in another embodiment, ALU(s) **710** may be external to a processor or other hardware logic device or circuit that uses them (e.g., a co-processor). In at least one embodiment, ALUs **710** may be included within a processor's execution units or otherwise within a bank of ALUs accessible by a processor's execution units either within same processor or distributed between different processors of different types (e.g., central processing units, graphics processing units, fixed function units, etc.). In at least one embodiment, code and/or data storage **701**, code and/or data storage **705**, and activation storage **720** may be on same processor or other hardware logic device or circuit, whereas in another embodiment, they may be in different processors or other hardware logic devices or circuits, or some combination of same and different proces-

sors or other hardware logic devices or circuits. In at least one embodiment, any portion of activation storage **720** may be included with other on-chip or off-chip data storage, including a processor's L1, L2, or L3 cache or system memory. Furthermore, inferencing and/or training code may be stored with other code accessible to a processor or other hardware logic or circuit and fetched and/or processed using a processor's fetch, decode, scheduling, execution, retirement and/or other logical circuits.

[0057] In at least one embodiment, activation storage **720** may be cache memory, DRAM, SRAM, non-volatile memory (e.g., Flash memory), or other storage. In at least one embodiment, activation storage **720** may be completely or partially within or external to one or more processors or other logical circuits. In at least one embodiment, choice of whether activation storage **720** is internal or external to a processor, for example, or comprised of DRAM, SRAM, Flash or some other storage type may depend on available storage on-chip versus off-chip, latency requirements of training and/or inferencing functions being performed, batch size of data used in inferencing and/or training of a neural network, or some combination of these factors. In at least one embodiment, inference and/or training logic **715** illustrated in FIG. **7***a* may be used in conjunction with an application-specific integrated circuit ("ASIC"), such as Tensorflow® Processing Unit from Google, an inference processing unit (IPU) from Graphcore™, or a Nervana® (e.g., "Lake Crest") processor from Intel Corp. In at least one embodiment, inference and/or training logic **715** illustrated in FIG. **7***a* may be used in conjunction with central processing unit ("CPU") hardware, graphics processing unit ("GPU") hardware or other hardware, such as field programmable gate arrays ("FPGAs").

[0058] FIG. **7***b* illustrates inference and/or training logic **715**, according to at least one or more embodiments. In at least one embodiment, inference and/or training logic **715** may include, without limitation, hardware logic in which computational resources are dedicated or otherwise exclusively used in conjunction with weight values or other information corresponding to one or more layers of neurons within a neural network. In at least one embodiment, inference and/or training logic **715** illustrated in FIG. **7***b* may be used in conjunction with an application-specific integrated circuit (ASIC), such as Tensorflow® Processing Unit from Google, an inference processing unit (IPU) from Graphcore™, or a Nervana® (e.g., "Lake Crest") processor from Intel Corp. In at least one embodiment, inference and/or training logic **715** illustrated in FIG. **7***b* may be used in conjunction with central processing unit (CPU) hardware, graphics processing unit (GPU) hardware or other hardware, such as field programmable gate arrays (FPGAs). In at least one embodiment, inference and/or training logic **715** includes, without limitation, code and/or data storage **701** and code and/or data storage **705**, which may be used to store code (e.g., graph code), weight values and/or other information, including bias values, gradient information, momentum values, and/or other parameter or hyperparameter information. In at least one embodiment illustrated in FIG. **7***b*, each of code and/or data storage **701** and code and/or data storage **705** is associated with a dedicated computational resource, such as computational hardware **702** and computational hardware **706**, respectively. In at least one embodiment, each of computational hardware **702** and computational hardware **706** comprises one or more ALUs that perform mathematical functions, such as linear algebraic functions, only on information stored in code and/or data storage **701** and code and/or data storage **705**, respectively, result of which is stored in activation storage **720**.

[0059] In at least one embodiment, each of code and/or data storage **701** and **705** and corresponding computational hardware **702** and **706**, respectively, correspond to different layers of a neural network, such that resulting activation from one "storage/computational pair **701**/**702**" of code and/or data storage **701** and computational hardware **702** is provided as an input to "storage/computational pair **705**/**706**" of code and/or data storage **705** and computational hardware **706**, in order to mirror conceptual organization of a neural network. In at least one embodiment, each of storage/computational pairs **701**/**702** and **705**/**706** may correspond to more than one neural network layer. In at least one embodiment, additional storage/computation pairs (not shown) subsequent to or in parallel with storage computation pairs **701**/**702** and **705**/**706** may be included in inference and/or training logic **715**.

Data Center

[0060] FIG. **8** illustrates an example data center **800**, in which at least one embodiment may be used. In at least one embodiment, data center **800** includes a data center infrastructure layer **810**, a framework layer **820**, a software layer **830**, and an application layer **840**.

[0061] In at least one embodiment, as shown in FIG. **8**, data center infrastructure layer **810** may include a resource orchestrator **812**, grouped computing resources **814**, and node computing resources ("node C.R.s") **816**(**1**)-**816**(N), where "N" represents any whole, positive integer. In at least one embodiment, node C.R.s **816**(**1**)-**816**(N) may include, but are not limited to, any number of central processing units ("CPUs") or other processors (including accelerators, field programmable gate arrays (FPGAs), graphics processors, etc.), memory devices (e.g., dynamic read-only memory), storage devices (e.g., solid state or disk drives), network input/output ("NW I/O") devices, network switches, virtual machines ("VMs"), power modules, and cooling modules, etc. In at least one embodiment, one or more node C.R.s from among node C.R.s **816**(**1**)-**816**(N) may be a server having one or more of above-mentioned computing resources.

[0062] In at least one embodiment, grouped computing resources **814** may include separate groupings of node C.R.s housed within one or more racks (not shown), or many racks housed in data centers at various geographical locations (also not shown). Separate groupings of node C.R.s within grouped computing resources **814** may include grouped compute, network, memory or storage resources that may be configured or allocated to support one or more workloads. In at least one embodiment, several node C.R.s including CPUs or processors may grouped within one or more racks to provide compute resources to support one or more workloads. In at least one embodiment, one or more racks may also include any number of power modules, cooling modules, and network switches, in any combination.

[0063] In at least one embodiment, resource orchestrator **812** may configure or otherwise control one or more node C.R.s **816**(**1**)-**816**(N) and/or grouped computing resources **814**. In at least one embodiment, resource orchestrator **812** may include a software design infrastructure ("SDI") man-

agement entity for data center **800**. In at least one embodiment, resource orchestrator may include hardware, software or some combination thereof.

[0064] In at least one embodiment, as shown in FIG. **8**, framework layer **820** includes a job scheduler **822**, a configuration manager **824**, a resource manager **826** and a distributed file system **828**. In at least one embodiment, framework layer **820** may include a framework to support software **832** of software layer **830** and/or one or more application(s) **842** of application layer **840**. In at least one embodiment, software **832** or application(s) **842** may respectively include web-based service software or applications, such as those provided by Amazon Web Services, Google Cloud and Microsoft Azure. In at least one embodiment, framework layer **820** may be, but is not limited to, a type of free and open-source software web application framework such as Apache Spark™ (hereinafter "Spark") that may utilize distributed file system **828** for large-scale data processing (e.g., "big data"). In at least one embodiment, job scheduler **822** may include a Spark driver to facilitate scheduling of workloads supported by various layers of data center **800**. In at least one embodiment, configuration manager **824** may be capable of configuring different layers such as software layer **830** and framework layer **820** including Spark and distributed file system **828** for supporting large-scale data processing. In at least one embodiment, resource manager **826** may be capable of managing clustered or grouped computing resources mapped to or allocated for support of distributed file system **828** and job scheduler **822**. In at least one embodiment, clustered or grouped computing resources may include grouped computing resource **814** at data center infrastructure layer **810**. In at least one embodiment, resource manager **826** may coordinate with resource orchestrator **812** to manage these mapped or allocated computing resources.

[0065] In at least one embodiment, software **832** included in software layer **830** may include software used by at least portions of node C.R.s **816**(**1**)-**816**(N), grouped computing resources **814**, and/or distributed file system **828** of framework layer **820**. The one or more types of software may include, but are not limited to, Internet web page search software, e-mail virus scan software, database software, and streaming video content software.

[0066] In at least one embodiment, application(s) **842** included in application layer **840** may include one or more types of applications used by at least portions of node C.R.s **816**(**1**)-**816**(N), grouped computing resources **814**, and/or distributed file system **828** of framework layer **820**. One or more types of applications may include, but are not limited to, any number of a genomics application, a cognitive compute, and a machine learning application, including training or inferencing software, machine learning framework software (e.g., PyTorch, TensorFlow, Caffe, etc.) or other machine learning applications used in conjunction with one or more embodiments.

[0067] In at least one embodiment, any of configuration manager **824**, resource manager **826**, and resource orchestrator **812** may implement any number and type of self-modifying actions based on any amount and type of data acquired in any technically feasible fashion. In at least one embodiment, self-modifying actions may relieve a data center operator of data center **800** from making possibly bad configuration decisions and possibly avoiding underutilized and/or poor performing portions of a data center.

[0068] In at least one embodiment, data center **800** may include tools, services, software or other resources to train one or more machine learning models or predict or infer information using one or more machine learning models according to one or more embodiments described herein. For example, in at least one embodiment, a machine learning model may be trained by calculating weight parameters according to a neural network architecture using software and computing resources described above with respect to data center **800**. In at least one embodiment, trained machine learning models corresponding to one or more neural networks may be used to infer or predict information using resources described above with respect to data center **800** by using weight parameters calculated through one or more training techniques described herein.

[0069] In at least one embodiment, data center may use CPUs, application-specific integrated circuits (ASICs), GPUs, FPGAs, or other hardware to perform training and/or inferencing using above-described resources. Moreover, one or more software and/or hardware resources described above may be configured as a service to allow users to train or performing inferencing of information, such as image recognition, speech recognition, or other artificial intelligence services.

[0070] Inference and/or training logic **715** are used to perform inferencing and/or training operations associated with one or more embodiments. Details regarding inference and/or training logic **715** are provided below in conjunction with FIGS. **7**A and/or **7**B. In at least one embodiment, inference and/or training logic **715** may be used in system FIG. **8** for inferencing or predicting operations based, at least in part, on weight parameters calculated using neural network training operations, neural network functions and/or architectures, or neural network use cases described herein.

[0071] Such components can be used to identify unlabeled images that include representations of objects of interest using a semantic matching process.

Computer Systems

[0072] FIG. **9** is a block diagram illustrating an exemplary computer system, which may be a system with interconnected devices and components, a system-on-a-chip (SOC) or some combination thereof **900** formed with a processor that may include execution units to execute an instruction, according to at least one embodiment. In at least one embodiment, computer system **900** may include, without limitation, a component, such as a processor **902** to employ execution units including logic to perform algorithms for process data, in accordance with present disclosure, such as in embodiment described herein. In at least one embodiment, computer system **900** may include processors, such as PENTIUM® Processor family, Xeon™, Itanium®, XScale™ and/or StrongARM™, Intel® Core™, or Intel® Nervana™ microprocessors available from Intel Corporation of Santa Clara, California, although other systems (including PCs having other microprocessors, engineering workstations, set-top boxes and like) may also be used. In at least one embodiment, computer system **900** may execute a version of WINDOWS' operating system available from Microsoft Corporation of Redmond, Wash., although other operating systems (UNIX and Linux for example), embedded software, and/or graphical user interfaces, may also be used.

[0073] Embodiments may be used in other devices such as handheld devices and embedded applications. Some examples of handheld devices include cellular phones, Internet Protocol devices, digital cameras, personal digital assistants ("PDAs"), and handheld PCs. In at least one embodiment, embedded applications may include a microcontroller, a digital signal processor ("DSP"), system on a chip, network computers ("NetPCs"), set-top boxes, network hubs, wide area network ("WAN") switches, or any other system that may perform one or more instructions in accordance with at least one embodiment.

[0074] In at least one embodiment, computer system **900** may include, without limitation, processor **902** that may include, without limitation, one or more execution units **908** to perform machine learning model training and/or inferencing according to techniques described herein. In at least one embodiment, computer system **900** is a single processor desktop or server system, but in another embodiment computer system **900** may be a multiprocessor system. In at least one embodiment, processor **902** may include, without limitation, a complex instruction set computer ("CISC") microprocessor, a reduced instruction set computing ("RISC") microprocessor, a very long instruction word ("VLIW") microprocessor, a processor implementing a combination of instruction sets, or any other processor device, such as a digital signal processor, for example. In at least one embodiment, processor **902** may be coupled to a processor bus **910** that may transmit data signals between processor **902** and other components in computer system **900**.

[0075] In at least one embodiment, processor **902** may include, without limitation, a Level 1 ("L1") internal cache memory ("cache") **904**. In at least one embodiment, processor **902** may have a single internal cache or multiple levels of internal cache. In at least one embodiment, cache memory may reside external to processor **902**. Other embodiments may also include a combination of both internal and external caches depending on particular implementation and needs. In at least one embodiment, register file **906** may store different types of data in various registers including, without limitation, integer registers, floating point registers, status registers, and instruction pointer register.

[0076] In at least one embodiment, execution unit **908**, including, without limitation, logic to perform integer and floating point operations, also resides in processor **902**. In at least one embodiment, processor **902** may also include a microcode ("ucode") read only memory ("ROM") that stores microcode for certain macro instructions. In at least one embodiment, execution unit **908** may include logic to handle a packed instruction set **909**. In at least one embodiment, by including packed instruction set **909** in an instruction set of a general-purpose processor **902**, along with associated circuitry to execute instructions, operations used by many multimedia applications may be performed using packed data in a general-purpose processor **902**. In one or more embodiments, many multimedia applications may be accelerated and executed more efficiently by using full width of a processor's data bus for performing operations on packed data, which may eliminate need to transfer smaller units of data across processor's data bus to perform one or more operations one data element at a time.

[0077] In at least one embodiment, execution unit **908** may also be used in microcontrollers, embedded processors, graphics devices, DSPs, and other types of logic circuits. In at least one embodiment, computer system **900** may include, without limitation, a memory **920**. In at least one embodiment, memory **920** may be implemented as a Dynamic Random Access Memory ("DRAM") device, a Static Random Access Memory ("SRAM") device, flash memory device, or other memory device. In at least one embodiment, memory **920** may store instruction(s) **919** and/or data **921** represented by data signals that may be executed by processor **902**.

[0078] In at least one embodiment, system logic chip may be coupled to processor bus **910** and memory **920**. In at least one embodiment, system logic chip may include, without limitation, a memory controller hub ("MCH") **916**, and processor **902** may communicate with MCH **916** via processor bus **910**. In at least one embodiment, MCH **916** may provide a high bandwidth memory path **918** to memory **920** for instruction and data storage and for storage of graphics commands, data and textures. In at least one embodiment, MCH **916** may direct data signals between processor **902**, memory **920**, and other components in computer system **900** and to bridge data signals between processor bus **910**, memory **920**, and a system I/O **922**. In at least one embodiment, system logic chip may provide a graphics port for coupling to a graphics controller. In at least one embodiment, MCH **916** may be coupled to memory **920** through a high bandwidth memory path **918** and graphics/video card **912** may be coupled to MCH **916** through an Accelerated Graphics Port ("AGP") interconnect **914**.

[0079] In at least one embodiment, computer system **900** may use system I/O **922** that is a proprietary hub interface bus to couple MCH **916** to I/O controller hub ("ICH") **930**. In at least one embodiment, ICH **930** may provide direct connections to some I/O devices via a local I/O bus. In at least one embodiment, local I/O bus may include, without limitation, a high-speed I/O bus for connecting peripherals to memory **920**, chipset, and processor **902**. Examples may include, without limitation, an audio controller **929**, a firmware hub ("flash BIOS") **928**, a wireless transceiver **926**, a data storage **924**, a legacy I/O controller **923** containing user input and keyboard interfaces **925**, a serial expansion port **927**, such as Universal Serial Bus ("USB"), and a network controller **934**. Data storage **924** may comprise a hard disk drive, a floppy disk drive, a CD-ROM device, a flash memory device, or other mass storage device.

[0080] In at least one embodiment, FIG. **9** illustrates a system, which includes interconnected hardware devices or "chips", whereas in other embodiments, FIG. **9** may illustrate an exemplary System on a Chip ("SoC"). In at least one embodiment, devices may be interconnected with proprietary interconnects, standardized interconnects (e.g., PCIe) or some combination thereof. In at least one embodiment, one or more components of computer system **900** are interconnected using compute express link (CXL) interconnects.

[0081] Inference and/or training logic **715** are used to perform inferencing and/or training operations associated with one or more embodiments. Details regarding inference and/or training logic **715** are provided below in conjunction with FIGS. **7**A and/or **7**B. In at least one embodiment, inference and/or training logic **715** may be used in system FIG. **9** for inferencing or predicting operations based, at least in part, on weight parameters calculated using neural network training operations, neural network functions and/or architectures, or neural network use cases described herein.

[0082] Such components can be used to identify unlabeled images that include representations of objects of interest using a semantic matching process.

[0083] FIG. **10** is a block diagram illustrating an electronic device **1000** for utilizing a processor **1010**, according to at least one embodiment. In at least one embodiment, electronic device **1000** may be, for example and without limitation, a notebook, a tower server, a rack server, a blade server, a laptop, a desktop, a tablet, a mobile device, a phone, an embedded computer, or any other suitable electronic device.

[0084] In at least one embodiment, system **1000** may include, without limitation, processor **1010** communicatively coupled to any suitable number or kind of components, peripherals, modules, or devices. In at least one embodiment, processor **1010** coupled using a bus or interface, such as a 1° C. bus, a System Management Bus ("SMBus"), a Low Pin Count (LPC) bus, a Serial Peripheral Interface ("SPI"), a High Definition Audio ("HDA") bus, a Serial Advance Technology Attachment ("SATA") bus, a Universal Serial Bus ("USB") (versions **1**, **2**, **3**), or a Universal Asynchronous Receiver/Transmitter ("UART") bus. In at least one embodiment, FIG. **10** illustrates a system, which includes interconnected hardware devices or "chips", whereas in other embodiments, FIG. **10** may illustrate an exemplary System on a Chip ("SoC"). In at least one embodiment, devices illustrated in FIG. **10** may be interconnected with proprietary interconnects, standardized interconnects (e.g., PCIe) or some combination thereof. In at least one embodiment, one or more components of FIG. **10** are interconnected using compute express link (CXL) interconnects.

[0085] In at least one embodiment, FIG. **10** may include a display **1024**, a touch screen **1025**, a touch pad **1030**, a Near Field Communications unit ("NFC") **1045**, a sensor hub **1040**, a thermal sensor **1046**, an Express Chipset ("EC") **1035**, a Trusted Platform Module ("TPM") **1038**, BIOS/firmware/flash memory ("BIOS, FW Flash") **1022**, a DSP **1060**, a drive **1020** such as a Solid State Disk ("SSD") or a Hard Disk Drive ("HDD"), a wireless local area network unit ("WLAN") **1050**, a Bluetooth unit **1052**, a Wireless Wide Area Network unit ("WWAN") **1056**, a Global Positioning System (GPS) **1055**, a camera ("USB 3.0 camera") **1054** such as a USB 3.0 camera, and/or a Low Power Double Data Rate ("LPDDR") memory unit ("LPDDR3") **1015** implemented in, for example, LPDDR3 standard. These components may each be implemented in any suitable manner.

[0086] In at least one embodiment, other components may be communicatively coupled to processor **1010** through components discussed above. In at least one embodiment, an accelerometer **1041**, Ambient Light Sensor ("ALS") **1042**, compass **1043**, and a gyroscope **1044** may be communicatively coupled to sensor hub **1040**. In at least one embodiment, thermal sensor **1039**, a fan **1037**, a keyboard **1046**, and a touch pad **1030** may be communicatively coupled to EC **1035**. In at least one embodiment, speaker **1063**, headphones **1064**, and microphone ("mic") **1065** may be communicatively coupled to an audio unit ("audio codec and class d amp") **1062**, which may in turn be communicatively coupled to DSP **1060**. In at least one embodiment, audio unit **1064** may include, for example and without limitation, an audio coder/decoder ("codec") and a class D amplifier. In at least one embodiment, SIM card ("SIM") **1057** may be communicatively coupled to WWAN unit **1056**. In at least one embodiment, components such as WLAN unit **1050** and Bluetooth unit **1052**, as well as WWAN unit **1056** may be implemented in a Next Generation Form Factor ("NGFF").

[0087] Inference and/or training logic **715** are used to perform inferencing and/or training operations associated with one or more embodiments. Details regarding inference and/or training logic **715** are provided below in conjunction with FIGS. **7***a* and/or **7***b*. In at least one embodiment, inference and/or training logic **715** may be used in system FIG. **10** for inferencing or predicting operations based, at least in part, on weight parameters calculated using neural network training operations, neural network functions and/or architectures, or neural network use cases described herein.

[0088] Such components can be used to identify unlabeled images that include representations of objects of interest using a semantic matching process.

[0089] FIG. **11** is a block diagram of a processing system, according to at least one embodiment. In at least one embodiment, system **1100** includes one or more processors **1102** and one or more graphics processors **1108**, and may be a single processor desktop system, a multiprocessor workstation system, or a server system having a large number of processors **1102** or processor cores **1107**. In at least one embodiment, system **1100** is a processing platform incorporated within a system-on-a-chip (SoC) integrated circuit for use in mobile, handheld, or embedded devices.

[0090] In at least one embodiment, system **1100** can include, or be incorporated within a server-based gaming platform, a game console, including a game and media console, a mobile gaming console, a handheld game console, or an online game console. In at least one embodiment, system **1100** is a mobile phone, smart phone, tablet computing device or mobile Internet device. In at least one embodiment, processing system **1100** can also include, couple with, or be integrated within a wearable device, such as a smart watch wearable device, smart eyewear device, augmented reality device, or virtual reality device. In at least one embodiment, processing system **1100** is a television or set top box device having one or more processors **1102** and a graphical interface generated by one or more graphics processors **1108**.

[0091] In at least one embodiment, one or more processors **1102** each include one or more processor cores **1107** to process instructions which, when executed, perform operations for system and user software. In at least one embodiment, each of one or more processor cores **1107** is configured to process a specific instruction set **1109**. In at least one embodiment, instruction set **1109** may facilitate Complex Instruction Set Computing (CISC), Reduced Instruction Set Computing (RISC), or computing via a Very Long Instruction Word (VLIW). In at least one embodiment, processor cores **1107** may each process a different instruction set **1109**, which may include instructions to facilitate emulation of other instruction sets. In at least one embodiment, processor core **1107** may also include other processing devices, such a Digital Signal Processor (DSP).

[0092] In at least one embodiment, processor **1102** includes cache memory **1104**. In at least one embodiment, processor **1102** can have a single internal cache or multiple levels of internal cache. In at least one embodiment, cache memory is shared among various components of processor **1102**. In at least one embodiment, processor **1102** also uses

an external cache (e.g., a Level-3 (L3) cache or Last Level Cache (LLC)) (not shown), which may be shared among processor cores **1107** using known cache coherency techniques. In at least one embodiment, register file **1106** is additionally included in processor **1102** which may include different types of registers for storing different types of data (e.g., integer registers, floating point registers, status registers, and an instruction pointer register). In at least one embodiment, register file **1106** may include general-purpose registers or other registers.

[0093] In at least one embodiment, one or more processor(s) **1102** are coupled with one or more interface bus(es) **1110** to transmit communication signals such as address, data, or control signals between processor **1102** and other components in system **1100**. In at least one embodiment, interface bus **1110**, in one embodiment, can be a processor bus, such as a version of a Direct Media Interface (DMI) bus. In at least one embodiment, interface **1110** is not limited to a DMI bus, and may include one or more Peripheral Component Interconnect buses (e.g., PCI, PCI Express), memory busses, or other types of interface busses. In at least one embodiment processor(s) **1102** include an integrated memory controller **1116** and a platform controller hub **1130**. In at least one embodiment, memory controller **1116** facilitates communication between a memory device and other components of system **1100**, while platform controller hub (PCH) **1130** provides connections to I/O devices via a local I/O bus.

[0094] In at least one embodiment, memory device **1120** can be a dynamic random access memory (DRAM) device, a static random access memory (SRAM) device, flash memory device, phase-change memory device, or some other memory device having suitable performance to serve as process memory. In at least one embodiment memory device **1120** can operate as system memory for system **1100**, to store data **1122** and instructions **1121** for use when one or more processors **1102** executes an application or process. In at least one embodiment, memory controller **1116** also couples with an optional external graphics processor **1112**, which may communicate with one or more graphics processors **1108** in processors **1102** to perform graphics and media operations. In at least one embodiment, a display device **1111** can connect to processor(s) **1102**. In at least one embodiment display device **1111** can include one or more of an internal display device, as in a mobile electronic device or a laptop device or an external display device attached via a display interface (e.g., DisplayPort, etc.). In at least one embodiment, display device **1111** can include a head mounted display (HMD) such as a stereoscopic display device for use in virtual reality (VR) applications or augmented reality (AR) applications.

[0095] In at least one embodiment, platform controller hub **1130** enables peripherals to connect to memory device **1120** and processor **1102** via a high-speed I/O bus. In at least one embodiment, I/O peripherals include, but are not limited to, an audio controller **1146**, a network controller **1134**, a firmware interface **1128**, a wireless transceiver **1126**, touch sensors **1125**, a data storage device **1124** (e.g., hard disk drive, flash memory, etc.). In at least one embodiment, data storage device **1124** can connect via a storage interface (e.g., SATA) or via a peripheral bus, such as a Peripheral Component Interconnect bus (e.g., PCI, PCI Express). In at least one embodiment, touch sensors **1125** can include touch screen sensors, pressure sensors, or fingerprint sensors. In at least one embodiment, wireless transceiver **1126** can be a Wi-Fi transceiver, a Bluetooth transceiver, or a mobile network transceiver such as a 3G, 4G, or Long Term Evolution (LTE) transceiver. In at least one embodiment, firmware interface **1128** enables communication with system firmware, and can be, for example, a unified extensible firmware interface (UEFI). In at least one embodiment, network controller **1134** can enable a network connection to a wired network. In at least one embodiment, a high-performance network controller (not shown) couples with interface bus **1110**. In at least one embodiment, audio controller **1146** is a multi-channel high definition audio controller. In at least one embodiment, system **1100** includes an optional legacy I/O controller **1140** for coupling legacy (e.g., Personal System 2 (PS/2)) devices to system. In at least one embodiment, platform controller hub **1130** can also connect to one or more Universal Serial Bus (USB) controllers **1142** connect input devices, such as keyboard and mouse **1143** combinations, a camera **1144**, or other USB input devices.

[0096] In at least one embodiment, an instance of memory controller **1116** and platform controller hub **1130** may be integrated into a discreet external graphics processor, such as external graphics processor **1112**. In at least one embodiment, platform controller hub **1130** and/or memory controller **1116** may be external to one or more processor(s) **1102**. For example, in at least one embodiment, system **1100** can include an external memory controller **1116** and platform controller hub **1130**, which may be configured as a memory controller hub and peripheral controller hub within a system chipset that is in communication with processor(s) **1102**.

[0097] Inference and/or training logic **715** are used to perform inferencing and/or training operations associated with one or more embodiments. Details regarding inference and/or training logic **715** are provided below in conjunction with FIGS. **7**A and/or **7**B. In at least one embodiment portions or all of inference and/or training logic **715** may be incorporated into graphics processor **1500**. For example, in at least one embodiment, training and/or inferencing techniques described herein may use one or more of ALUs embodied in a graphics processor. Moreover, in at least one embodiment, inferencing and/or training operations described herein may be done using logic other than logic illustrated in FIG. **7**A or **7**B. In at least one embodiment, weight parameters may be stored in on-chip or off-chip memory and/or registers (shown or not shown) that configure ALUs of a graphics processor to perform one or more machine learning algorithms, neural network architectures, use cases, or training techniques described herein.

[0098] Such components can be used to identify unlabeled images that include representations of objects of interest using a semantic matching process.

[0099] FIG. **12** is a block diagram of a processor **1200** having one or more processor cores **1202**A-**1202**N, an integrated memory controller **1214**, and an integrated graphics processor **1208**, according to at least one embodiment. In at least one embodiment, processor **1200** can include additional cores up to and including additional core **1202**N represented by dashed lined boxes. In at least one embodiment, each of processor cores **1202**A-**1202**N includes one or more internal cache units **1204**A-**1204**N. In at least one embodiment, each processor core also has access to one or more shared cached units **1206**.

[0100] In at least one embodiment, internal cache units **1204**A-**1204**N and shared cache units **1206** represent a

cache memory hierarchy within processor **1200**. In at least one embodiment, cache memory units **1204**A-**1204**N may include at least one level of instruction and data cache within each processor core and one or more levels of shared mid-level cache, such as a Level 2 (L2), Level 3 (L3), Level 4 (L4), or other levels of cache, where a highest level of cache before external memory is classified as an LLC. In at least one embodiment, cache coherency logic maintains coherency between various cache units **1206** and **1204**A-**1204**N.

[0101] In at least one embodiment, processor **1200** may also include a set of one or more bus controller units **1216** and a system agent core **1210**. In at least one embodiment, one or more bus controller units **1216** manage a set of peripheral buses, such as one or more PCI or PCI express busses. In at least one embodiment, system agent core **1210** provides management functionality for various processor components. In at least one embodiment, system agent core **1210** includes one or more integrated memory controllers **1214** to manage access to various external memory devices (not shown).

[0102] In at least one embodiment, one or more of processor cores **1202**A-**1202**N include support for simultaneous multi-threading. In at least one embodiment, system agent core **1210** includes components for coordinating and operating cores **1202**A-**1202**N during multi-threaded processing. In at least one embodiment, system agent core **1210** may additionally include a power control unit (PCU), which includes logic and components to regulate one or more power states of processor cores **1202**A-**1202**N and graphics processor **1208**.

[0103] In at least one embodiment, processor **1200** additionally includes graphics processor **1208** to execute graphics processing operations. In at least one embodiment, graphics processor **1208** couples with shared cache units **1206**, and system agent core **1210**, including one or more integrated memory controllers **1214**. In at least one embodiment, system agent core **1210** also includes a display controller **1211** to drive graphics processor output to one or more coupled displays. In at least one embodiment, display controller **1211** may also be a separate module coupled with graphics processor **1208** via at least one interconnect, or may be integrated within graphics processor **1208**.

[0104] In at least one embodiment, a ring based interconnect unit **1212** is used to couple internal components of processor **1200**. In at least one embodiment, an alternative interconnect unit may be used, such as a point-to-point interconnect, a switched interconnect, or other techniques. In at least one embodiment, graphics processor **1208** couples with ring interconnect **1212** via an I/O link **1213**.

[0105] In at least one embodiment, I/O link **1213** represents at least one of multiple varieties of I/O interconnects, including an on package I/O interconnect which facilitates communication between various processor components and a high-performance embedded memory module **1218**, such as an eDRAM module. In at least one embodiment, each of processor cores **1202**A-**1202**N and graphics processor **1208** use embedded memory modules **1218** as a shared Last Level Cache.

[0106] In at least one embodiment, processor cores **1202**A-**1202**N are homogenous cores executing a common instruction set architecture. In at least one embodiment, processor cores **1202**A-**1202**N are heterogeneous in terms of instruction set architecture (ISA), where one or more of processor cores **1202**A-**1202**N execute a common instruction set, while one or more other cores of processor cores **1202**A-**1202**N executes a subset of a common instruction set or a different instruction set. In at least one embodiment, processor cores **1202**A-**1202**N are heterogeneous in terms of microarchitecture, where one or more cores having a relatively higher power consumption couple with one or more power cores having a lower power consumption. In at least one embodiment, processor **1200** can be implemented on one or more chips or as an SoC integrated circuit.

[0107] Inference and/or training logic **715** are used to perform inferencing and/or training operations associated with one or more embodiments. Details regarding inference and/or training logic **715** are provided below in conjunction with FIGS. **7***a* and/or **7***b*. In at least one embodiment portions or all of inference and/or training logic **715** may be incorporated into processor **1200**. For example, in at least one embodiment, training and/or inferencing techniques described herein may use one or more of ALUs embodied in graphics processor **1512**, graphics core(s) **1202**A-**1202**N, or other components in FIG. **12**. Moreover, in at least one embodiment, inferencing and/or training operations described herein may be done using logic other than logic illustrated in FIG. **7**A or **7**B. In at least one embodiment, weight parameters may be stored in on-chip or off-chip memory and/or registers (shown or not shown) that configure ALUs of graphics processor **1200** to perform one or more machine learning algorithms, neural network architectures, use cases, or training techniques described herein.

[0108] Such components can be used to identify unlabeled images that include representations of objects of interest using a semantic matching process.

Virtualized Computing Platform

[0109] FIG. **13** is an example data flow diagram for a process **1300** of generating and deploying an image processing and inferencing pipeline, in accordance with at least one embodiment. In at least one embodiment, process **1300** may be deployed for use with imaging devices, processing devices, and/or other device types at one or more facilities **1302**. Process **1300** may be executed within a training system **1304** and/or a deployment system **1306**. In at least one embodiment, training system **1304** may be used to perform training, deployment, and implementation of machine learning models (e.g., neural networks, object detection algorithms, computer vision algorithms, etc.) for use in deployment system **1306**. In at least one embodiment, deployment system **1306** may be configured to offload processing and compute resources among a distributed computing environment to reduce infrastructure requirements at facility **1302**. In at least one embodiment, one or more applications in a pipeline may use or call upon services (e.g., inference, visualization, compute, AI, etc.) of deployment system **1306** during execution of applications.

[0110] In at least one embodiment, some of applications used in advanced processing and inferencing pipelines may use machine learning models or other AI to perform one or more processing steps. In at least one embodiment, machine learning models may be trained at facility **1302** using data **1308** (such as imaging data) generated at facility **1302** (and stored on one or more picture archiving and communication system (PACS) servers at facility **1302**), may be trained using imaging or sequencing data **1308** from another facility (ies), or a combination thereof. In at least one embodiment,

training system **1304** may be used to provide applications, services, and/or other resources for generating working, deployable machine learning models for deployment system **1306**.

[0111] In at least one embodiment, model registry **1324** may be backed by object storage that may support versioning and object metadata. In at least one embodiment, object storage may be accessible through, for example, a cloud storage (e.g., cloud **1426** of FIG. **14**) compatible application programming interface (API) from within a cloud platform. In at least one embodiment, machine learning models within model registry **1324** may uploaded, listed, modified, or deleted by developers or partners of a system interacting with an API. In at least one embodiment, an API may provide access to methods that allow users with appropriate credentials to associate models with applications, such that models may be executed as part of execution of containerized instantiations of applications.

[0112] In at least one embodiment, training pipeline **1404** (FIG. **14**) may include a scenario where facility **1302** is training their own machine learning model, or has an existing machine learning model that needs to be optimized or updated. In at least one embodiment, imaging data **1308** generated by imaging device(s), sequencing devices, and/or other device types may be received. In at least one embodiment, once imaging data **1308** is received, AI-assisted annotation **1310** may be used to aid in generating annotations corresponding to imaging data **1308** to be used as ground truth data for a machine learning model. In at least one embodiment, AI-assisted annotation **1310** may include one or more machine learning models (e.g., convolutional neural networks (CNNs)) that may be trained to generate annotations corresponding to certain types of imaging data **1308** (e.g., from certain devices). In at least one embodiment, AI-assisted annotations **1310** may then be used directly, or may be adjusted or fine-tuned using an annotation tool to generate ground truth data. In at least one embodiment, AI-assisted annotations **1310**, labeled clinic data **1312**, or a combination thereof may be used as ground truth data for training a machine learning model. In at least one embodiment, a trained machine learning model may be referred to as output model **1316**, and may be used by deployment system **1306**, as described herein.

[0113] In at least one embodiment, training pipeline **1404** (FIG. **14**) may include a scenario where facility **1302** needs a machine learning model for use in performing one or more processing tasks for one or more applications in deployment system **1306**, but facility **1302** may not currently have such a machine learning model (or may not have a model that is optimized, efficient, or effective for such purposes). In at least one embodiment, an existing machine learning model may be selected from a model registry **1324**. In at least one embodiment, model registry **1324** may include machine learning models trained to perform a variety of different inference tasks on imaging data. In at least one embodiment, machine learning models in model registry **1324** may have been trained on imaging data from different facilities than facility **1302** (e.g., facilities remotely located). In at least one embodiment, machine learning models may have been trained on imaging data from one location, two locations, or any number of locations. In at least one embodiment, when being trained on imaging data from a specific location, training may take place at that location, or at least in a manner that protects confidentiality of imaging data or restricts imaging data from being transferred off-premises. In at least one embodiment, once a model is trained—or partially trained—at one location, a machine learning model may be added to model registry **1324**. In at least one embodiment, a machine learning model may then be retrained, or updated, at any number of other facilities, and a retrained or updated model may be made available in model registry **1324**. In at least one embodiment, a machine learning model may then be selected from model registry **1324**—and referred to as output model **1316**—and may be used in deployment system **1306** to perform one or more processing tasks for one or more applications of a deployment system.

[0114] In at least one embodiment, training pipeline **1404** (FIG. **14**), a scenario may include facility **1302** requiring a machine learning model for use in performing one or more processing tasks for one or more applications in deployment system **1306**, but facility **1302** may not currently have such a machine learning model (or may not have a model that is optimized, efficient, or effective for such purposes). In at least one embodiment, a machine learning model selected from model registry **1324** may not be fine-tuned or optimized for imaging data **1308** generated at facility **1302** because of differences in populations, robustness of training data used to train a machine learning model, diversity in anomalies of training data, and/or other issues with training data. In at least one embodiment, AI-assisted annotation **1310** may be used to aid in generating annotations corresponding to imaging data **1308** to be used as ground truth data for retraining or updating a machine learning model. In at least one embodiment, labeled data **1312** may be used as ground truth data for training a machine learning model. In at least one embodiment, retraining or updating a machine learning model may be referred to as model training **1314**. In at least one embodiment, model training **1314**—e.g., AI-assisted annotations **1310**, labeled clinic data **1312**, or a combination thereof—may be used as ground truth data for retraining or updating a machine learning model. In at least one embodiment, a trained machine learning model may be referred to as output model **1316**, and may be used by deployment system **1306**, as described herein.

[0115] In at least one embodiment, deployment system **1306** may include software **1318**, services **1320**, hardware **1322**, and/or other components, features, and functionality. In at least one embodiment, deployment system **1306** may include a software "stack," such that software **1318** may be built on top of services **1320** and may use services **1320** to perform some or all of processing tasks, and services **1320** and software **1318** may be built on top of hardware **1322** and use hardware **1322** to execute processing, storage, and/or other compute tasks of deployment system **1306**. In at least one embodiment, software **1318** may include any number of different containers, where each container may execute an instantiation of an application. In at least one embodiment, each application may perform one or more processing tasks in an advanced processing and inferencing pipeline (e.g., inferencing, object detection, feature detection, segmentation, image enhancement, calibration, etc.). In at least one embodiment, an advanced processing and inferencing pipeline may be defined based on selections of different containers that are desired or required for processing imaging data **1308**, in addition to containers that receive and configure imaging data for use by each container and/or for use by facility **1302** after processing through a pipeline (e.g., to

convert outputs back to a usable data type). In at least one embodiment, a combination of containers within software **1318** (e.g., that make up a pipeline) may be referred to as a virtual instrument (as described in more detail herein), and a virtual instrument may leverage services **1320** and hardware **1322** to execute some or all processing tasks of applications instantiated in containers.

[0116] In at least one embodiment, a data processing pipeline may receive input data (e.g., imaging data **1308**) in a specific format in response to an inference request (e.g., a request from a user of deployment system **1306**). In at least one embodiment, input data may be representative of one or more images, video, and/or other data representations generated by one or more imaging devices. In at least one embodiment, data may undergo pre-processing as part of data processing pipeline to prepare data for processing by one or more applications. In at least one embodiment, post-processing may be performed on an output of one or more inferencing tasks or other processing tasks of a pipeline to prepare an output data for a next application and/or to prepare output data for transmission and/or use by a user (e.g., as a response to an inference request). In at least one embodiment, inferencing tasks may be performed by one or more machine learning models, such as trained or deployed neural networks, which may include output models **1316** of training system **1304**.

[0117] In at least one embodiment, tasks of data processing pipeline may be encapsulated in a container(s) that each represents a discrete, fully functional instantiation of an application and virtualized computing environment that is able to reference machine learning models. In at least one embodiment, containers or applications may be published into a private (e.g., limited access) area of a container registry (described in more detail herein), and trained or deployed models may be stored in model registry **1324** and associated with one or more applications. In at least one embodiment, images of applications (e.g., container images) may be available in a container registry, and once selected by a user from a container registry for deployment in a pipeline, an image may be used to generate a container for an instantiation of an application for use by a user's system.

[0118] In at least one embodiment, developers (e.g., software developers, clinicians, doctors, etc.) may develop, publish, and store applications (e.g., as containers) for performing image processing and/or inferencing on supplied data. In at least one embodiment, development, publishing, and/or storing may be performed using a software development kit (SDK) associated with a system (e.g., to ensure that an application and/or container developed is compliant with or compatible with a system). In at least one embodiment, an application that is developed may be tested locally (e.g., at a first facility, on data from a first facility) with an SDK which may support at least some of services **1320** as a system (e.g., system **1400** of FIG. **14**). In at least one embodiment, because DICOM objects may contain anywhere from one to hundreds of images or other data types, and due to a variation in data, a developer may be responsible for managing (e.g., setting constructs for, building pre-processing into an application, etc.) extraction and preparation of incoming data. In at least one embodiment, once validated by system **1400** (e.g., for accuracy), an application may be available in a container registry for selection and/or implementation by a user to perform one or more processing tasks with respect to data at a facility (e.g., a second facility) of a user.

[0119] In at least one embodiment, developers may then share applications or containers through a network for access and use by users of a system (e.g., system **1400** of FIG. **14**). In at least one embodiment, completed and validated applications or containers may be stored in a container registry and associated machine learning models may be stored in model registry **1324**. In at least one embodiment, a requesting entity-who provides an inference or image processing request—may browse a container registry and/or model registry **1324** for an application, container, dataset, machine learning model, etc., select a desired combination of elements for inclusion in data processing pipeline, and submit an imaging processing request. In at least one embodiment, a request may include input data (and associated patient data, in some examples) that is necessary to perform a request, and/or may include a selection of application(s) and/or machine learning models to be executed in processing a request. In at least one embodiment, a request may then be passed to one or more components of deployment system **1306** (e.g., a cloud) to perform processing of data processing pipeline. In at least one embodiment, processing by deployment system **1306** may include referencing selected elements (e.g., applications, containers, models, etc.) from a container registry and/or model registry **1324**. In at least one embodiment, once results are generated by a pipeline, results may be returned to a user for reference (e.g., for viewing in a viewing application suite executing on a local, on-premises workstation or terminal).

[0120] In at least one embodiment, to aid in processing or execution of applications or containers in pipelines, services **1320** may be leveraged. In at least one embodiment, services **1320** may include compute services, artificial intelligence (AI) services, visualization services, and/or other service types. In at least one embodiment, services **1320** may provide functionality that is common to one or more applications in software **1318**, so functionality may be abstracted to a service that may be called upon or leveraged by applications. In at least one embodiment, functionality provided by services **1320** may run dynamically and more efficiently, while also scaling well by allowing applications to process data in parallel (e.g., using a parallel computing platform **1430** (FIG. **14**)). In at least one embodiment, rather than each application that shares a same functionality offered by a service **1320** being required to have a respective instance of service **1320**, service **1320** may be shared between and among various applications. In at least one embodiment, services may include an inference server or engine that may be used for executing detection or segmentation tasks, as non-limiting examples. In at least one embodiment, a model training service may be included that may provide machine learning model training and/or retraining capabilities. In at least one embodiment, a data augmentation service may further be included that may provide GPU accelerated data (e.g., DICOM, RIS, CIS, REST compliant, RPC, raw, etc.) extraction, resizing, scaling, and/or other augmentation. In at least one embodiment, a visualization service may be used that may add image rendering effects-such as ray-tracing, rasterization, denoising, sharpening, etc.—to add realism to two-dimensional (2D) and/or three-dimensional (3D) models. In at least one embodiment, virtual instrument services may be included

that provide for beam-forming, segmentation, inferencing, imaging, and/or support for other applications within pipelines of virtual instruments.

[0121] In at least one embodiment, where a service **1320** includes an AI service (e.g., an inference service), one or more machine learning models may be executed by calling upon (e.g., as an API call) an inference service (e.g., an inference server) to execute machine learning model(s), or processing thereof, as part of application execution. In at least one embodiment, where another application includes one or more machine learning models for segmentation tasks, an application may call upon an inference service to execute machine learning models for performing one or more of processing operations associated with segmentation tasks. In at least one embodiment, software **1318** implementing advanced processing and inferencing pipeline that includes segmentation application and anomaly detection application may be streamlined because each application may call upon a same inference service to perform one or more inferencing tasks.

[0122] In at least one embodiment, hardware **1322** may include GPUs, CPUs, graphics cards, an AI/deep learning system (e.g., an AI supercomputer, such as NVIDIA's DGX), a cloud platform, or a combination thereof. In at least one embodiment, different types of hardware **1322** may be used to provide efficient, purpose-built support for software **1318** and services **1320** in deployment system **1306**. In at least one embodiment, use of GPU processing may be implemented for processing locally (e.g., at facility **1302**), within an AI/deep learning system, in a cloud system, and/or in other processing components of deployment system **1306** to improve efficiency, accuracy, and efficacy of image processing and generation. In at least one embodiment, software **1318** and/or services **1320** may be optimized for GPU processing with respect to deep learning, machine learning, and/or high-performance computing, as non-limiting examples. In at least one embodiment, at least some of computing environment of deployment system **1306** and/or training system **1304** may be executed in a datacenter one or more supercomputers or high performance computing systems, with GPU optimized software (e.g., hardware and software combination of NVIDIA's DGX System). In at least one embodiment, hardware **1322** may include any number of GPUs that may be called upon to perform processing of data in parallel, as described herein. In at least one embodiment, cloud platform may further include GPU processing for GPU-optimized execution of deep learning tasks, machine learning tasks, or other computing tasks. In at least one embodiment, cloud platform (e.g., NVIDIA's NGC) may be executed using an AI/deep learning supercomputer(s) and/or GPU-optimized software (e.g., as provided on NVIDIA's DGX Systems) as a hardware abstraction and scaling platform. In at least one embodiment, cloud platform may integrate an application container clustering system or orchestration system (e.g., KUBERNETES) on multiple GPUs to enable seamless scaling and load balancing.

[0123] FIG. **14** is a system diagram for an example system **1400** for generating and deploying an imaging deployment pipeline, in accordance with at least one embodiment. In at least one embodiment, system **1400** may be used to implement process **1300** of FIG. **13** and/or other processes including advanced processing and inferencing pipelines. In at least one embodiment, system **1400** may include training system **1304** and deployment system **1306**. In at least one embodiment, training system **1304** and deployment system **1306** may be implemented using software **1318**, services **1320**, and/or hardware **1322**, as described herein.

[0124] In at least one embodiment, system **1400** (e.g., training system **1304** and/or deployment system **1306**) may implemented in a cloud computing environment (e.g., using cloud **1426**). In at least one embodiment, system **1400** may be implemented locally with respect to a healthcare services facility, or as a combination of both cloud and local computing resources. In at least one embodiment, access to APIs in cloud **1426** may be restricted to authorized users through enacted security measures or protocols. In at least one embodiment, a security protocol may include web tokens that may be signed by an authentication (e.g., AuthN, AuthZ, Gluecon, etc.) service and may carry appropriate authorization. In at least one embodiment, APIs of virtual instruments (described herein), or other instantiations of system **1400**, may be restricted to a set of public IPs that have been vetted or authorized for interaction.

[0125] In at least one embodiment, various components of system **1400** may communicate between and among one another using any of a variety of different network types, including but not limited to local area networks (LANs) and/or wide area networks (WANs) via wired and/or wireless communication protocols. In at least one embodiment, communication between facilities and components of system **1400** (e.g., for transmitting inference requests, for receiving results of inference requests, etc.) may be communicated over data bus (ses), wireless data protocols (Wi-Fi), wired data protocols (e.g., Ethernet), etc.

[0126] In at least one embodiment, training system **1304** may execute training pipelines **1404**, similar to those described herein with respect to FIG. **13**. In at least one embodiment, where one or more machine learning models are to be used in deployment pipelines **1410** by deployment system **1306**, training pipelines **1404** may be used to train or retrain one or more (e.g. pre-trained) models, and/or implement one or more of pre-trained models **1406** (e.g., without a need for retraining or updating). In at least one embodiment, as a result of training pipelines **1404**, output model(s) **1316** may be generated. In at least one embodiment, training pipelines **1404** may include any number of processing steps, such as but not limited to imaging data (or other input data) conversion or adaption In at least one embodiment, for different machine learning models used by deployment system **1306**, different training pipelines **1404** may be used. In at least one embodiment, training pipeline **1404** similar to a first example described with respect to FIG. **13** may be used for a first machine learning model, training pipeline **1404** similar to a second example described with respect to FIG. **13** may be used for a second machine learning model, and training pipeline **1404** similar to a third example described with respect to FIG. **13** may be used for a third machine learning model. In at least one embodiment, any combination of tasks within training system **1304** may be used depending on what is required for each respective machine learning model. In at least one embodiment, one or more of machine learning models may already be trained and ready for deployment so machine learning models may not undergo any processing by training system **1304**, and may be implemented by deployment system **1306**.

[0127] In at least one embodiment, output model(s) **1316** and/or pre-trained model(s) **1406** may include any types of

machine learning models depending on implementation or embodiment. In at least one embodiment, and without limitation, machine learning models used by system **1400** may include machine learning model(s) using linear regression, logistic regression, decision trees, support vector machines (SVM), Naïve Bayes, k-nearest neighbor (Knn), K means clustering, random forest, dimensionality reduction algorithms, gradient boosting algorithms, neural networks (e.g., auto-encoders, convolutional, recurrent, perceptrons, Long/Short Term Memory (LSTM), Hopfield, Boltzmann, deep belief, deconvolutional, generative adversarial, liquid state machine, etc.), and/or other types of machine learning models.

[0128] In at least one embodiment, training pipelines **1404** may include AI-assisted annotation, as described in more detail herein with respect to at least FIG. **15**B. In at least one embodiment, labeled data **1312** (e.g., traditional annotation) may be generated by any number of techniques. In at least one embodiment, labels or other annotations may be generated within a drawing program (e.g., an annotation program), a computer aided design (CAD) program, a labeling program, another type of program suitable for generating annotations or labels for ground truth, and/or may be hand drawn, in some examples. In at least one embodiment, ground truth data may be synthetically produced (e.g., generated from computer models or renderings), real produced (e.g., designed and produced from real-world data), machine-automated (e.g., using feature analysis and learning to extract features from data and then generate labels), human annotated (e.g., labeler, or annotation expert, defines location of labels), and/or a combination thereof. In at least one embodiment, for each instance of imaging data **1308** (or other data type used by machine learning models), there may be corresponding ground truth data generated by training system **1304**. In at least one embodiment, AI-assisted annotation may be performed as part of deployment pipelines **1410**; either in addition to, or in lieu of AI-assisted annotation included in training pipelines **1404**. In at least one embodiment, system **1400** may include a multi-layer platform that may include a software layer (e.g., software **1318**) of diagnostic applications (or other application types) that may perform one or more medical imaging and diagnostic functions. In at least one embodiment, system **1400** may be communicatively coupled to (e.g., via encrypted links) PACS server networks of one or more facilities. In at least one embodiment, system **1400** may be configured to access and referenced data from PACS servers to perform operations, such as training machine learning models, deploying machine learning models, image processing, inferencing, and/or other operations.

[0129] In at least one embodiment, a software layer may be implemented as a secure, encrypted, and/or authenticated API through which applications or containers may be invoked (e.g., called) from an external environment(s) (e.g., facility **1302**). In at least one embodiment, applications may then call or execute one or more services **1320** for performing compute, AI, or visualization tasks associated with respective applications, and software **1318** and/or services **1320** may leverage hardware **1322** to perform processing tasks in an effective and efficient manner.

[0130] In at least one embodiment, deployment system **1306** may execute deployment pipelines **1410**. In at least one embodiment, deployment pipelines **1410** may include any number of applications that may be sequentially, non-sequentially, or otherwise applied to imaging data (and/or other data types) generated by imaging devices, sequencing devices, genomics devices, etc.—including AI-assisted annotation, as described above. In at least one embodiment, as described herein, a deployment pipeline **1410** for an individual device may be referred to as a virtual instrument for a device (e.g., a virtual ultrasound instrument, a virtual CT scan instrument, a virtual sequencing instrument, etc.). In at least one embodiment, for a single device, there may be more than one deployment pipeline **1410** depending on information desired from data generated by a device. In at least one embodiment, where detections of anomalies are desired from an MRI machine, there may be a first deployment pipeline **1410**, and where image enhancement is desired from output of an MRI machine, there may be a second deployment pipeline **1410**.

[0131] In at least one embodiment, an image generation application may include a processing task that includes use of a machine learning model. In at least one embodiment, a user may desire to use their own machine learning model, or to select a machine learning model from model registry **1324**. In at least one embodiment, a user may implement their own machine learning model or select a machine learning model for inclusion in an application for performing a processing task. In at least one embodiment, applications may be selectable and customizable, and by defining constructs of applications, deployment and implementation of applications for a particular user are presented as a more seamless user experience. In at least one embodiment, by leveraging other features of system **1400**—such as services **1320** and hardware **1322**—deployment pipelines **1410** may be even more user friendly, provide for easier integration, and produce more accurate, efficient, and timely results.

[0132] In at least one embodiment, deployment system **1306** may include a user interface **1414** (e.g., a graphical user interface, a web interface, etc.) that may be used to select applications for inclusion in deployment pipeline(s) **1410**, arrange applications, modify or change applications or parameters or constructs thereof, use and interact with deployment pipeline(s) **1410** during set-up and/or deployment, and/or to otherwise interact with deployment system **1306**. In at least one embodiment, although not illustrated with respect to training system **1304**, user interface **1414** (or a different user interface) may be used for selecting models for use in deployment system **1306**, for selecting models for training, or retraining, in training system **1304**, and/or for otherwise interacting with training system **1304**.

[0133] In at least one embodiment, pipeline manager **1412** may be used, in addition to an application orchestration system **1428**, to manage interaction between applications or containers of deployment pipeline(s) **1410** and services **1320** and/or hardware **1322**. In at least one embodiment, pipeline manager **1412** may be configured to facilitate interactions from application to application, from application to service **1320**, and/or from application or service to hardware **1322**. In at least one embodiment, although illustrated as included in software **1318**, this is not intended to be limiting, and in some examples (e.g., as illustrated in FIG. **12***cc*) pipeline manager **1412** may be included in services **1320**. In at least one embodiment, application orchestration system **1428** (e.g., Kubernetes, DOCKER, etc.) may include a container orchestration system that may group applications into containers as logical units for coordination, management, scaling, and deployment. In at least one embodiment, by asso-

ciating applications from deployment pipeline(s) **1410** (e.g., a reconstruction application, a segmentation application, etc.) with individual containers, each application may execute in a self-contained environment (e.g., at a kernel level) to increase speed and efficiency.

[0134] In at least one embodiment, each application and/or container (or image thereof) may be individually developed, modified, and deployed (e.g., a first user or developer may develop, modify, and deploy a first application and a second user or developer may develop, modify, and deploy a second application separate from a first user or developer), which may allow for focus on, and attention to, a task of a single application and/or container(s) without being hindered by tasks of another application(s) or container(s). In at least one embodiment, communication, and cooperation between different containers or applications may be aided by pipeline manager **1412** and application orchestration system **1428**. In at least one embodiment, so long as an expected input and/or output of each container or application is known by a system (e.g., based on constructs of applications or containers), application orchestration system **1428** and/or pipeline manager **1412** may facilitate communication among and between, and sharing of resources among and between, each of applications or containers. In at least one embodiment, because one or more of applications or containers in deployment pipeline(s) **1410** may share same services and resources, application orchestration system **1428** may orchestrate, load balance, and determine sharing of services or resources between and among various applications or containers. In at least one embodiment, a scheduler may be used to track resource requirements of applications or containers, current usage or planned usage of these resources, and resource availability. In at least one embodiment, a scheduler may thus allocate resources to different applications and distribute resources between and among applications in view of requirements and availability of a system. In some examples, a scheduler (and/or other component of application orchestration system **1428**) may determine resource availability and distribution based on constraints imposed on a system (e.g., user constraints), such as quality of service (QoS), urgency of need for data outputs (e.g., to determine whether to execute real-time processing or delayed processing), etc.

[0135] In at least one embodiment, services **1320** leveraged by and shared by applications or containers in deployment system **1306** may include compute services **1416**, AI services **1418**, visualization services **1420**, and/or other service types. In at least one embodiment, applications may call (e.g., execute) one or more of services **1320** to perform processing operations for an application. In at least one embodiment, compute services **1416** may be leveraged by applications to perform super-computing or other high-performance computing (HPC) tasks. In at least one embodiment, compute service(s) **1416** may be leveraged to perform parallel processing (e.g., using a parallel computing platform **1430**) for processing data through one or more of applications and/or one or more tasks of a single application, substantially simultaneously. In at least one embodiment, parallel computing platform **1430** (e.g., NVIDIA's CUDA) may enable general purpose computing on GPUs (GPGPU) (e.g., GPUs **1422**). In at least one embodiment, a software layer of parallel computing platform **1430** may provide access to virtual instruction sets and parallel computational elements of GPUs, for execution of compute kernels. In at least one embodiment, parallel computing platform **1430** may include memory and, in some embodiments, a memory may be shared between and among multiple containers, and/or between and among different processing tasks within a single container. In at least one embodiment, inter-process communication (IPC) calls may be generated for multiple containers and/or for multiple processes within a container to use same data from a shared segment of memory of parallel computing platform **1430** (e.g., where multiple different stages of an application or multiple applications are processing same information). In at least one embodiment, rather than making a copy of data and moving data to different locations in memory (e.g., a read/write operation), same data in same location of a memory may be used for any number of processing tasks (e.g., at a same time, at different times, etc.). In at least one embodiment, as data is used to generate new data as a result of processing, this information of a new location of data may be stored and shared between various applications. In at least one embodiment, location of data and a location of updated or modified data may be part of a definition of how a payload is understood within containers.

[0136] In at least one embodiment, AI services **1418** may be leveraged to perform inferencing services for executing machine learning model(s) associated with applications (e.g., tasked with performing one or more processing tasks of an application). In at least one embodiment, AI services **1418** may leverage AI system **1424** to execute machine learning model(s) (e.g., neural networks, such as CNNs) for segmentation, reconstruction, object detection, feature detection, classification, and/or other inferencing tasks. In at least one embodiment, applications of deployment pipeline(s) **1410** may use one or more of output models **1316** from training system **1304** and/or other models of applications to perform inference on imaging data. In at least one embodiment, two or more examples of inferencing using application orchestration system **1428** (e.g., a scheduler) may be available. In at least one embodiment, a first category may include a high priority/low latency path that may achieve higher service level agreements, such as for performing inference on urgent requests during an emergency, or for a radiologist during diagnosis. In at least one embodiment, a second category may include a standard priority path that may be used for requests that may be non-urgent or where analysis may be performed at a later time. In at least one embodiment, application orchestration system **1428** may distribute resources (e.g., services **1320** and/or hardware **1322**) based on priority paths for different inferencing tasks of AI services **1418**.

[0137] In at least one embodiment, shared storage may be mounted to AI services **1418** within system **1400**. In at least one embodiment, shared storage may operate as a cache (or other storage device type) and may be used to process inference requests from applications. In at least one embodiment, when an inference request is submitted, a request may be received by a set of API instances of deployment system **1306**, and one or more instances may be selected (e.g., for best fit, for load balancing, etc.) to process a request. In at least one embodiment, to process a request, a request may be entered into a database, a machine learning model may be located from model registry **1324** if not already in a cache, a validation step may ensure appropriate machine learning model is loaded into a cache (e.g., shared storage), and/or a copy of a model may be saved to a cache. In at least one

embodiment, a scheduler (e.g., of pipeline manager **1412**) may be used to launch an application that is referenced in a request if an application is not already running or if there are not enough instances of an application. In at least one embodiment, if an inference server is not already launched to execute a model, an inference server may be launched. Any number of inference servers may be launched per model. In at least one embodiment, in a pull model, in which inference servers are clustered, models may be cached whenever load balancing is advantageous. In at least one embodiment, inference servers may be statically loaded in corresponding, distributed servers.

[0138] In at least one embodiment, inferencing may be performed using an inference server that runs in a container. In at least one embodiment, an instance of an inference server may be associated with a model (and optionally a plurality of versions of a model). In at least one embodiment, if an instance of an inference server does not exist when a request to perform inference on a model is received, a new instance may be loaded. In at least one embodiment, when starting an inference server, a model may be passed to an inference server such that a same container may be used to serve different models so long as inference server is running as a different instance.

[0139] In at least one embodiment, during application execution, an inference request for a given application may be received, and a container (e.g., hosting an instance of an inference server) may be loaded (if not already), and a start procedure may be called. In at least one embodiment, pre-processing logic in a container may load, decode, and/or perform any additional pre-processing on incoming data (e.g., using a CPU(s) and/or GPU(s)). In at least one embodiment, once data is prepared for inference, a container may perform inference as necessary on data. In at least one embodiment, this may include a single inference call on one image (e.g., a hand X-ray), or may require inference on hundreds of images (e.g., a chest CT). In at least one embodiment, an application may summarize results before completing, which may include, without limitation, a single confidence score, pixel level-segmentation, voxel-level segmentation, generating a visualization, or generating text to summarize findings. In at least one embodiment, different models or applications may be assigned different priorities. For example, some models may have a real-time (TAT<1 min) priority while others may have lower priority (e.g., TAT<10 min). In at least one embodiment, model execution times may be measured from requesting institution or entity and may include partner network traversal time, as well as execution on an inference service.

[0140] In at least one embodiment, transfer of requests between services **1320** and inference applications may be hidden behind a software development kit (SDK), and robust transport may be provide through a queue. In at least one embodiment, a request will be placed in a queue via an API for an individual application/tenant ID combination and an SDK will pull a request from a queue and give a request to an application. In at least one embodiment, a name of a queue may be provided in an environment from where an SDK will pick it up. In at least one embodiment, asynchronous communication through a queue may be useful as it may allow any instance of an application to pick up work as it becomes available. Results may be transferred back through a queue, to ensure no data is lost. In at least one embodiment, queues may also provide an ability to segment work, as highest priority work may go to a queue with most instances of an application connected to it, while lowest priority work may go to a queue with a single instance connected to it that processes tasks in an order received. In at least one embodiment, an application may run on a GPU-accelerated instance generated in cloud **1426**, and an inference service may perform inferencing on a GPU.

[0141] In at least one embodiment, visualization services **1420** may be leveraged to generate visualizations for viewing outputs of applications and/or deployment pipeline(s) **1410**. In at least one embodiment, GPUs **1422** may be leveraged by visualization services **1420** to generate visualizations. In at least one embodiment, rendering effects, such as ray-tracing, may be implemented by visualization services **1420** to generate higher quality visualizations. In at least one embodiment, visualizations may include, without limitation, 2D image renderings, 3D volume renderings, 3D volume reconstruction, 2D tomographic slices, virtual reality displays, augmented reality displays, etc. In at least one embodiment, virtualized environments may be used to generate a virtual interactive display or environment (e.g., a virtual environment) for interaction by users of a system (e.g., doctors, nurses, radiologists, etc.). In at least one embodiment, visualization services **1420** may include an internal visualizer, cinematics, and/or other rendering or image processing capabilities or functionality (e.g., ray tracing, rasterization, internal optics, etc.).

[0142] In at least one embodiment, hardware **1322** may include GPUs **1422**, AI system **1424**, cloud **1426**, and/or any other hardware used for executing training system **1304** and/or deployment system **1306**. In at least one embodiment, GPUs **1422** (e.g., NVIDIA's TESLA and/or QUADRO GPUs) may include any number of GPUs that may be used for executing processing tasks of compute services **1416**, AI services **1418**, visualization services **1420**, other services, and/or any of features or functionality of software **1318**. For example, with respect to AI services **1418**, GPUs **1422** may be used to perform pre-processing on imaging data (or other data types used by machine learning models), post-processing on outputs of machine learning models, and/or to perform inferencing (e.g., to execute machine learning models). In at least one embodiment, cloud **1426**, AI system **1424**, and/or other components of system **1400** may use GPUs **1422**. In at least one embodiment, cloud **1426** may include a GPU-optimized platform for deep learning tasks. In at least one embodiment, AI system **1424** may use GPUs, and cloud **1426**—or at least a portion tasked with deep learning or inferencing—may be executed using one or more AI systems **1424**. As such, although hardware **1322** is illustrated as discrete components, this is not intended to be limiting, and any components of hardware **1322** may be combined with, or leveraged by, any other components of hardware **1322**.

[0143] In at least one embodiment, AI system **1424** may include a purpose-built computing system (e.g., a supercomputer or an HPC) configured for inferencing, deep learning, machine learning, and/or other artificial intelligence tasks. In at least one embodiment, AI system **1424** (e.g., NVIDIA's DGX) may include GPU-optimized software (e.g., a software stack) that may be executed using a plurality of GPUs **1422**, in addition to CPUs, RAM, storage, and/or other components, features, or functionality. In at least one embodiment, one or more AI systems **1424** may be

implemented in cloud **1426** (e.g., in a data center) for performing some or all of AI-based processing tasks of system **1400**.

[0144] In at least one embodiment, cloud **1426** may include a GPU-accelerated infrastructure (e.g., NVIDIA's NGC) that may provide a GPU-optimized platform for executing processing tasks of system **1400**. In at least one embodiment, cloud **1426** may include an AI system(s) **1424** for performing one or more of AI-based tasks of system **1400** (e.g., as a hardware abstraction and scaling platform). In at least one embodiment, cloud **1426** may integrate with application orchestration system **1428** leveraging multiple GPUs to enable seamless scaling and load balancing between and among applications and services **1320**. In at least one embodiment, cloud **1426** may tasked with executing at least some of services **1320** of system **1400**, including compute services **1416**, AI services **1418**, and/or visualization services **1420**, as described herein. In at least one embodiment, cloud **1426** may perform small and large batch inference (e.g., executing NVIDIA's TENSOR RT), provide an accelerated parallel computing API and platform **1430** (e.g., NVIDIA's CUDA), execute application orchestration system **1428** (e.g., KUBERNETES), provide a graphics rendering API and platform (e.g., for ray-tracing, 2D graphics, 3D graphics, and/or other rendering techniques to produce higher quality cinematics), and/or may provide other functionality for system **1400**.

[0145] FIG. **15**A illustrates a data flow diagram for a process **1500** to train, retrain, or update a machine learning model, in accordance with at least one embodiment. In at least one embodiment, process **1500** may be executed using, as a non-limiting example, system **1400** of FIG. **14**. In at least one embodiment, process **1500** may leverage services **1320** and/or hardware **1322** of system **1400**, as described herein. In at least one embodiment, refined models **1512** generated by process **1500** may be executed by deployment system **1306** for one or more containerized applications in deployment pipelines **1410**.

[0146] In at least one embodiment, model training **1314** may include retraining or updating an initial model **1504** (e.g., a pre-trained model) using new training data (e.g., new input data, such as customer dataset **1506**, and/or new ground truth data associated with input data). In at least one embodiment, to retrain, or update, initial model **1504**, output or loss layer(s) of initial model **1504** may be reset, or deleted, and/or replaced with an updated or new output or loss layer(s). In at least one embodiment, initial model **1504** may have previously fine-tuned parameters (e.g., weights and/or biases) that remain from prior training, so training or retraining **1314** may not take as long or require as much processing as training a model from scratch. In at least one embodiment, during model training **1314**, by having reset or replaced output or loss layer(s) of initial model **1504**, parameters may be updated and re-tuned for a new data set based on loss calculations associated with accuracy of output or loss layer(s) at generating predictions on new, customer dataset **1506** (e.g., image data **1308** of FIG. **13**).

[0147] In at least one embodiment, pre-trained models **1406** may be stored in a data store, or registry (e.g., model registry **1324** of FIG. **13**). In at least one embodiment, pre-trained models **1406** may have been trained, at least in part, at one or more facilities other than a facility executing process **1500**. In at least one embodiment, to protect privacy and rights of patients, subjects, or clients of different facilities, pre-trained models **1406** may have been trained, on-premise, using customer or patient data generated on-premise. In at least one embodiment, pre-trained models **1406** may be trained using cloud **1426** and/or other hardware **1322**, but confidential, privacy protected patient data may not be transferred to, used by, or accessible to any components of cloud **1426** (or other off premise hardware). In at least one embodiment, where a pre-trained model **1406** is trained at using patient data from more than one facility, pre-trained model **1406** may have been individually trained for each facility prior to being trained on patient or customer data from another facility. In at least one embodiment, such as where a customer or patient data has been released of privacy concerns (e.g., by waiver, for experimental use, etc.), or where a customer or patient data is included in a public data set, a customer or patient data from any number of facilities may be used to train pre-trained model **1406** on-premise and/or off premise, such as in a datacenter or other cloud computing infrastructure.

[0148] In at least one embodiment, when selecting applications for use in deployment pipelines **1410**, a user may also select machine learning models to be used for specific applications. In at least one embodiment, a user may not have a model for use, so a user may select a pre-trained model **1406** to use with an application. In at least one embodiment, pre-trained model **1406** may not be optimized for generating accurate results on customer dataset **1506** of a facility of a user (e.g., based on patient diversity, demographics, types of medical imaging devices used, etc.). In at least one embodiment, prior to deploying pre-trained model **1406** into deployment pipeline **1410** for use with an application(s), pre-trained model **1406** may be updated, retrained, and/or fine-tuned for use at a respective facility.

[0149] In at least one embodiment, a user may select pre-trained model **1406** that is to be updated, retrained, and/or fine-tuned, and pre-trained model **1406** may be referred to as initial model **1504** for training system **1304** within process **1500**. In at least one embodiment, customer dataset **1506** (e.g., imaging data, genomics data, sequencing data, or other data types generated by devices at a facility) may be used to perform model training **1314** (which may include, without limitation, transfer learning) on initial model **1504** to generate refined model **1512**. In at least one embodiment, ground truth data corresponding to customer dataset **1506** may be generated by training system **1304**. In at least one embodiment, ground truth data may be generated, at least in part, by clinicians, scientists, doctors, practitioners, at a facility (e.g., as labeled clinic data **1312** of FIG. **13**).

[0150] In at least one embodiment, AI-assisted annotation **1310** may be used in some examples to generate ground truth data. In at least one embodiment, AI-assisted annotation **1310** (e.g., implemented using an AI-assisted annotation SDK) may leverage machine learning models (e.g., neural networks) to generate suggested or predicted ground truth data for a customer dataset. In at least one embodiment, user **1510** may use annotation tools within a user interface (a graphical user interface (GUI)) on computing device **1508**.

[0151] In at least one embodiment, user **1510** may interact with a GUI via computing device **1508** to edit or fine-tune (auto) annotations. In at least one embodiment, a polygon editing feature may be used to move vertices of a polygon to more accurate or fine-tuned locations.

[0152] In at least one embodiment, once customer dataset **1506** has associated ground truth data, ground truth data (e.g., from AI-assisted annotation, manual labeling, etc.) may be used by during model training **1314** to generate refined model **1512**. In at least one embodiment, customer dataset **1506** may be applied to initial model **1504** any number of times, and ground truth data may be used to update parameters of initial model **1504** until an acceptable level of accuracy is attained for refined model **1512**. In at least one embodiment, once refined model **1512** is generated, refined model **1512** may be deployed within one or more deployment pipelines **1410** at a facility for performing one or more processing tasks with respect to medical imaging data.

[0153] In at least one embodiment, refined model **1512** may be uploaded to pre-trained models **1406** in model registry **1324** to be selected by another facility. In at least one embodiment, his process may be completed at any number of facilities such that refined model **1512** may be further refined on new datasets any number of times to generate a more universal model.

[0154] FIG. **15**B is an example illustration of a client-server architecture **1532** to enhance annotation tools with pre-trained annotation models, in accordance with at least one embodiment. In at least one embodiment, AI-assisted annotation tools **1536** may be instantiated based on a client-server architecture **1532**. In at least one embodiment, annotation tools **1536** in imaging applications may aid radiologists, for example, identify organs and abnormalities. In at least one embodiment, imaging applications may include software tools that help user **1510** to identify, as a non-limiting example, a few extreme points on a particular organ of interest in raw images **1534** (e.g., in a 3D MRI or CT scan) and receive auto-annotated results for all 2D slices of a particular organ. In at least one embodiment, results may be stored in a data store as training data **1538** and used as (for example and without limitation) ground truth data for training. In at least one embodiment, when computing device **1508** sends extreme points for AI-assisted annotation **1310**, a deep learning model, for example, may receive this data as input and return inference results of a segmented organ or abnormality. In at least one embodiment, pre-instantiated annotation tools, such as AI-Assisted Annotation Tool **1536**B in FIG. **15**B, may be enhanced by making API calls (e.g., API Call **1544**) to a server, such as an Annotation Assistant Server **1540** that may include a set of pre-trained models **1542** stored in an annotation model registry, for example. In at least one embodiment, an annotation model registry may store pre-trained models **1542** (e.g., machine learning models, such as deep learning models) that are pre-trained to perform AI-assisted annotation on a particular organ or abnormality. These models may be further updated by using training pipelines **1404**. In at least one embodiment, pre-installed annotation tools may be improved over time as new labeled clinic data **1312** is added.

[0155] Such components can be used to identify unlabeled images that include representations of objects of interest using a semantic matching process.

[0156] Other variations are within spirit of present disclosure. Thus, while disclosed techniques are susceptible to various modifications and alternative constructions, certain illustrated embodiments thereof are shown in drawings and have been described above in detail. It should be understood, however, that there is no intention to limit disclosure to specific form or forms disclosed, but on contrary, intention is to cover all modifications, alternative constructions, and equivalents falling within spirit and scope of disclosure, as defined in appended claims.

[0157] Use of terms "a" and "an" and "the" and similar referents in context of describing disclosed embodiments (especially in context of following claims) are to be construed to cover both singular and plural, unless otherwise indicated herein or clearly contradicted by context, and not as a definition of a term. Terms "comprising," "having," "including," and "containing" are to be construed as open-ended terms (meaning "including, but not limited to,") unless otherwise noted. Term "connected," when unmodified and referring to physical connections, is to be construed as partly or wholly contained within, attached to, or joined together, even if there is something intervening. Recitation of ranges of values herein are merely intended to serve as a shorthand method of referring individually to each separate value falling within range, unless otherwise indicated herein and each separate value is incorporated into specification as if it were individually recited herein. Use of term "set" (e.g., "a set of items") or "subset," unless otherwise noted or contradicted by context, is to be construed as a nonempty collection comprising one or more members. Further, unless otherwise noted or contradicted by context, term "subset" of a corresponding set does not necessarily denote a proper subset of corresponding set, but subset and corresponding set may be equal.

[0158] Conjunctive language, such as phrases of form "at least one of A, B, and C," or "at least one of A, B and C," unless specifically stated otherwise or otherwise clearly contradicted by context, is otherwise understood with context as used in general to present that an item, term, etc., may be either A or B or C, or any nonempty subset of set of A and B and C. For instance, in illustrative example of a set having three members, conjunctive phrases "at least one of A, B, and C" and "at least one of A, B and C" refer to any of following sets: {A}, {B}, {C}, {A, B}, {A, C}, {B, C}, {A, B, C}. Thus, such conjunctive language is not generally intended to imply that certain embodiments require at least one of A, at least one of B, and at least one of C each to be present. In addition, unless otherwise noted or contradicted by context, term "plurality" indicates a state of being plural (e.g., "a plurality of items" indicates multiple items). A plurality is at least two items, but can be more when so indicated either explicitly or by context. Further, unless stated otherwise or otherwise clear from context, phrase "based on" means "based at least in part on" and not "based solely on."

[0159] Operations of processes described herein can be performed in any suitable order unless otherwise indicated herein or otherwise clearly contradicted by context. In at least one embodiment, a process such as those processes described herein (or variations and/or combinations thereof) is performed under control of one or more computer systems configured with executable instructions and is implemented as code (e.g., executable instructions, one or more computer programs or one or more applications) executing collectively on one or more processors, by hardware or combinations thereof. In at least one embodiment, code is stored on a computer-readable storage medium, for example, in form of a computer program comprising a plurality of instructions executable by one or more processors. In at least one embodiment, a computer-readable storage medium is a

non-transitory computer-readable storage medium that excludes transitory signals (e.g., a propagating transient electric or electromagnetic transmission) but includes non-transitory data storage circuitry (e.g., buffers, cache, and queues) within transceivers of transitory signals. In at least one embodiment, code (e.g., executable code or source code) is stored on a set of one or more non-transitory computer-readable storage media having stored thereon executable instructions (or other memory to store executable instructions) that, when executed (i.e., as a result of being executed) by one or more processors of a computer system, cause computer system to perform operations described herein. A set of non-transitory computer-readable storage media, in at least one embodiment, comprises multiple non-transitory computer-readable storage media and one or more of individual non-transitory storage media of multiple non-transitory computer-readable storage media lack all of code while multiple non-transitory computer-readable storage media collectively store all of code. In at least one embodiment, executable instructions are executed such that different instructions are executed by different processors—for example, a non-transitory computer-readable storage medium store instructions and a main central processing unit ("CPU") executes some of instructions while a graphics processing unit ("GPU") executes other instructions. In at least one embodiment, different components of a computer system have separate processors and different processors execute different subsets of instructions.

[0160] Accordingly, in at least one embodiment, computer systems are configured to implement one or more services that singly or collectively perform operations of processes described herein and such computer systems are configured with applicable hardware and/or software that enable performance of operations. Further, a computer system that implements at least one embodiment of present disclosure is a single device and, in another embodiment, is a distributed computer system comprising multiple devices that operate differently such that distributed computer system performs operations described herein and such that a single device does not perform all operations.

[0161] Use of any and all examples, or exemplary language (e.g., "such as") provided herein, is intended merely to better illuminate embodiments of disclosure and does not pose a limitation on scope of disclosure unless otherwise claimed. No language in specification should be construed as indicating any non-claimed element as essential to practice of disclosure.

[0162] All references, including publications, patent applications, and patents, cited herein are hereby incorporated by reference to same extent as if each reference were individually and specifically indicated to be incorporated by reference and were set forth in its entirety herein.

[0163] In description and claims, terms "coupled" and "connected," along with their derivatives, may be used. It should be understood that these terms may be not intended as synonyms for each other. Rather, in particular examples, "connected" or "coupled" may be used to indicate that two or more elements are in direct or indirect physical or electrical contact with each other. "Coupled" may also mean that two or more elements are not in direct contact with each other, but yet still co-operate or interact with each other.

[0164] Unless specifically stated otherwise, it may be appreciated that throughout specification terms such as "processing," "computing," "calculating," "determining," or like, refer to action and/or processes of a computer or computing system, or similar electronic computing device, that manipulate and/or transform data represented as physical, such as electronic, quantities within computing system's registers and/or memories into other data similarly represented as physical quantities within computing system's memories, registers or other such information storage, transmission or display devices.

[0165] In a similar manner, term "processor" may refer to any device or portion of a device that processes electronic data from registers and/or memory and transform that electronic data into other electronic data that may be stored in registers and/or memory. As non-limiting examples, "processor" may be a CPU or a GPU. A "computing platform" may comprise one or more processors. As used herein, "software" processes may include, for example, software and/or hardware entities that perform work over time, such as tasks, threads, and intelligent agents. Also, each process may refer to multiple processes, for carrying out instructions in sequence or in parallel, continuously or intermittently. Terms "system" and "method" are used herein interchangeably insofar as system may embody one or more methods and methods may be considered a system.

[0166] In present document, references may be made to obtaining, acquiring, receiving, or inputting analog or digital data into a subsystem, computer system, or computer-implemented machine. Obtaining, acquiring, receiving, or inputting analog and digital data can be accomplished in a variety of ways such as by receiving data as a parameter of a function call or a call to an application programming interface. In some implementations, process of obtaining, acquiring, receiving, or inputting analog or digital data can be accomplished by transferring data via a serial or parallel interface. In another implementation, process of obtaining, acquiring, receiving, or inputting analog or digital data can be accomplished by transferring data via a computer network from providing entity to acquiring entity. References may also be made to providing, outputting, transmitting, sending, or presenting analog or digital data. In various examples, process of providing, outputting, transmitting, sending, or presenting analog or digital data can be accomplished by transferring data as an input or output parameter of a function call, a parameter of an application programming interface or interprocess communication mechanism.

[0167] Although discussion above sets forth example implementations of described techniques, other architectures may be used to implement described functionality, and are intended to be within scope of this disclosure. Furthermore, although specific distributions of responsibilities are defined above for purposes of discussion, various functions and responsibilities might be distributed and divided in different ways, depending on circumstances.

[0168] Furthermore, although subject matter has been described in language specific to structural features and/or methodological acts, it is to be understood that subject matter claimed in appended claims is not necessarily limited to specific features or acts described. Rather, specific features and acts are disclosed as exemplary forms of implementing the claims.

1. (canceled)

2. A computer-implemented method, comprising:

identifying, in a first image, one or more image regions corresponding to one or more first objects;

extracting one or more first semantic features corresponding to the one or more image regions;

determining similarity values between the one or more first semantic features and one or more second semantic features of a plurality of unlabeled images;

selecting, based at least on the similarity values, one or more unlabeled images from the plurality of unlabeled images based at least on the one or more unlabeled images including one or more second objects that are semantically similar to the one or more first objects; and

using the selected one or more unlabeled images as training or validation data for updating one or more parameters of one or more machine learning models.

3. The computer-implemented method of claim **2**, further comprising:

processing the first image using one or more second machine learning models to identify the one or more objects of interest.

4. The computer-implemented method of claim **2**, wherein the one or more unlabeled images are selected based on at least one of: the unlabeled images including highest similarity values; or the one or more unlabeled images including similarity values above a selection threshold.

5. The computer-implemented method of claim **2**, wherein the similarity values are determined using, at least in part, a template matching algorithm.

6. The computer-implemented method of claim **5**, wherein the template matching algorithm uses one or more similarity tensors.

7. The computer-implemented method of claim **2**, wherein the extracting the one or more first semantic features includes processing at least the one or more image regions using one or more second machine learning models.

8. The computer-implemented method of claim **2**, wherein the determining the similarity values includes performing at least one of: one or more cosine similarity evaluations for the one or more first semantic features with respect to the plurality of unlabeled images; or one or more Euclidian distance determinations for the one or more semantic feature templates with respect to the plurality of unlabeled images.

9. The computer-implemented method of claim **2**, further comprising:

identifying one or more bounding areas defining the one or more image regions, wherein the one or more first semantic features correspond to pixels within the one or more bounding areas.

10. The computer-implemented method of claim **2**, wherein the first image includes a plurality of objects of interest of one or more object classes.

11. At least one processor, comprising:

one or more circuits to:

generate one or more feature templates corresponding to an object of interest in a first image;

compare the one or more feature templates to one or more features of a plurality of second images;

select, based at least on the comparing, a second image from the plurality of second images; and

perform one or more operations with respect to the selected second image.

12. The at least one processor of claim **11**, wherein the one or more circuits are further to:

identify one or more bounding areas defining one or more regions of interest corresponding to the object of interest within the first image, further wherein the one or more feature templates correspond to the one or more regions of interest.

13. The at least one processor of claim **11**, wherein the one or more operations include at least one of: storing the selected second image as part of a training data set; or using the selected second image as training or validation data to update one or more parameters of a machine learning model.

14. The at least one processor of claim **11**, wherein the comparing includes performing at least one of: one or more cosine similarity evaluations for the one or more feature templates with respect to the plurality of second images; or one or more Euclidian distance determinations for the one or more feature templates with respect to the plurality of second images.

15. The at least one processor of claim **11**, wherein the comparing includes using, at least in part, a template matching algorithm.

16. The at least one processor of claim **11**, wherein the one or more circuits are comprised in at least one of:

a system for performing graphical rendering operations;

a system for performing simulation operations;

a system for performing simulation operations to test or validate autonomous machine applications;

a system for performing deep learning operations;

a system implemented using an edge device;

a system incorporating one or more Virtual Machines (VMs);

a system implemented at least partially in a data center; or

a system implemented at least partially using cloud computing resources.

17. A system comprising:

one or more processors to update one or more parameters of one or more neural networks using one or more training images of a training data set, the one or more training images selected from a plurality of images based at least on a comparison between one or more feature templates corresponding to an object of interest and one or more features of the plurality of images, the one or more feature templates generated using features extracted from one or more image regions of one or more images depicting the object of interest.

18. The system of claim **17**, wherein the updating of the one or more parameters of the one or more neural networks corresponds to training the one or more neural networks to perform object detection or classification with respect to the object of interest.

19. The system of claim **17**, wherein the comparison uses cosine similarity values.

20. The system of claim **17**, wherein the one or more processors are further to identify one or more bounding areas defining the one or more image regions.

21. The system of claim **17**, wherein the comparison includes using, at least in part, a template matching algorithm.
