Background/Summary

TECHNICAL FIELD

[0001] The present invention relates to a binding molecule having neutralizing activity against the coronavirus superfamily, and more specifically, to a binding molecule having excellent binding affinity and neutralizing efficacy against various coronavirus species that may infect humans, including not only wild type SARS-coronavirus-2 (SARS-CoV-2) and mutant viruses that may occur in the future, but also SARS-coronavirus-1 (SARS-CoV-1), Middle East respiratory syndrome coronavirus (MERS-CoV), etc., which infect humans, causing fatal diseases.

BACKGROUND ART

[0002] Coronaviruses refer to viruses belonging to the family Coronaviridae and are generally found not only in birds but also in various mammals including humans. It is known that there are various coronavirus species, and coronaviruses cause both respiratory and digestive infectious diseases depending on the characteristics of the virus and on the host. Coronaviruses are viruses that cause respiratory illnesses of varying severity from the common cold to fatal pneumonia. Viruses belonging to the family Coronaviridae generally have a single-stranded, infectious, positive sense RNA genome with a length of 27 to 32 kb, and contain a cap at the 5′ end of the genome and a poly A tail at the 3′ end. Coronaviruses have an envelope, and contain major outer membrane proteins such as spike (S) protein and envelope (E) protein. The spike protein is involved in viral infection and pathogenicity, such as neutralizing antibody induction, receptor binding, and membrane fusion, and the envelope (E) protein is involved in morphogenesis of viral particles and extracellular release of the virus after infection.

[0003] Seven types of coronavirus are known to cause disease in humans, and infection with three types among them may cause even more severe or fatal pneumonia in humans. The three types that are fatal to humans include SARS-coronavirus-1 (SARS-CoV-1), which was identified as the cause of the 2003 severe acute respiratory syndrome outbreak which was a worldwide problem, MERS-coronavirus (MERS-CoV), which was identified as the cause of the 2012 Middle East respiratory syndrome outbreak, and the new coronavirus severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), which was first found in Wuhan, China in late 2019 and identified as the cause of coronavirus infection 2019 (COVID-19).

[0004] Severe acute respiratory syndrome (SARS) coronavirus 1 (SARS-CoV-1) is surrounded by a spherical envelope, like other coronaviruses, and has crown-like spikes (spike protein, S protein) on its surface. Severe acute respiratory syndrome caused by SARS coronavirus was first identified in China, and resulted in more than 8,000 cases and more than 800 deaths worldwide by mid-2003. So far, there is no antiviral agent that can treat human SARS coronavirus infection. However, ribavirin is used in the early stage of the infection, and high-concentration steroids may be used to suppress immune-mediated damage to infected tissues.

[0005] Middle East respiratory syndrome (MERS) coronavirus (MERS-CoV) has a single positive-stranded RNA genome, and the genes thereof are arranged in the order of RNA polymerase gene, structural protein genes, envelope protein, membrane protein, and nucleocapsid protein. The virus that causes Middle East respiratory syndrome (MERS) is a coronavirus similar to the virus that causes severe acute respiratory syndrome (SARS). There is no specific treatment for MERS, and nonsteroidal anti-inflammatory drugs (NSAIDs) such as acetaminophen or ibuprofen are administered to relieve fever and muscle pain.

[0006] Severe acute respiratory syndrome (SARS) coronavirus 2 (SARS-CoV-2) is a positive-sense single-stranded RNA coronavirus when subjected to DNA sequencing. SARS-CoV-2 is contagious to humans and is the cause of coronavirus disease 2019 (COVID-19). The first outbreak of COVID-19 occurred in Wuhan, Hubei Province, China.

[0007] People infected with SARS-CoV-2 may exhibit mild to severe symptoms such as fever, cough, shortness of breath, and diarrhea. People with complications or illnesses and the elderly are more likely to die.

[0008] In particular, early detection and treatment are very important because people with underlying diseases such as heart disease and diabetes are more susceptible to infection and more likely to suffer from complications or organ damage. From Dec. 8, 2019 to Mar. 20, 2020, there were 245,550 patients, among whom 10,049 died, which is a mortality rate of 4.09% (WHO). The virus spread to 177 countries, including Korea, by 2020.

[0009] Currently, there is no therapeutic agent for coronavirus disease 2019 (COVID-19), and therapeutic effects are expected to be exhibited by administering existing therapeutic agents to patients. Ebola therapeutic agents or candidates, for example, antiviral drugs such as favipiravir, remdesivir, and galidesivir, and a hepatitis C drug such as ribavirin, are being used as therapeutic agents for COVID-19. In addition, the antimalarial drug chloroquine has also been shown to be effective against COVID-19, and thus is in open-label clinical trials. However, ribavirin, which is a hepatitis C therapeutic drug, may have severe side effects such as anemia, and interferon, which is an antiviral drug, is also recommended to be used with caution because of the various side effects thereof.

[0010] Although these drugs have been used in the treatment of COVID-19 patients and show therapeutic effects thereon, it has not yet been clearly proven on what mechanism they are effective. In China, it was announced that plasma therapy of injecting the plasma of patients who had recovered from COVID-19 was effective in the treatment of severely ill patients, but the therapeutic effect thereof is unclear and is highly uncertain.

[0011] In Korea, the COVID-19 Central Clinical Trial TF (Task Force) established a treatment principle for COVID-19 on Feb. 13, 2020, and announced that Kaletra, which is an AIDS therapeutic agent, and chloroquine and hydroxychloroquine, which are antimalarial drugs, are recommended as the first-line therapeutic agents, and ribavirin and interferon are not recommended as the first-line therapeutic agents due to side effects thereof. As for mild cases or young patients, and 10 days after the onset of the disease, it was judged that the symptoms would improve without administration of an antiviral drug, and it was agreed to administer antiviral drugs to the elderly, patients with underlying diseases, and severely ill patients.

[0012] The US CDC i) announced that COVID-19 could become endemic like MERS rather than a seasonal pandemic virus and cause infection, and ii) mentioned the need to strengthen surveillance so that data-based conclusions can be drawn although there is no evidence that the coronavirus is lurking in the real community due to the spread of the virus to the community at some point this year or next year (Feb. 13, 2020).

[0013] The Korea Disease Control and Prevention Agency (formerly Korea Centers for Disease Control and Prevention) announced that i) COVID-19 could be a long-term epidemic like influenza and thus it should be included in monitoring programs such as that used for influenza, and ii) coronaviruses (4 types) that are prevalent among people are also prevalent from winter to spring, leaving the possibility that COVID-19 could also become endemic (Feb. 17, 2020).

[0014] Unlike SARS and MERS, there are concerns about the realization of the COVID-19 pandemic, but there is the possibility of a lull after spring (April), so there are many experts who take a careful approach depending on the progress thereof. Due to the lack of information on COVID-19, experts have different opinions on future developments, but few experts predict that it will be resolved in a short time. Although further progress of COVID-19 will be influenced by the accuracy of analysis of prevalence and characteristics of COVID-19 and by how long the crisis from COVID-19 will last, there are concerns about the possibility of endemic disease if it is spread worldwide through asymptomatic infected people. There is an urgent need to prepare countermeasures for the likelihood of recurrence of COVID-19 worldwide.

[0015] In addition, recently, there have been more than 50,000 confirmed cases of COVID-19 per day in the United States alone, and it is the opinion of the academic community that the occurrence of about 200,000 confirmed cases of COVID-19 per day around the world is due to mutation of the virus. Research results that coronaviruses mutate into a contagious form and that mutation occurs in the spike protein are amplifying concerns, and if mutation occurs in a part playing an important role in viral infection, such as the spike protein, it may also influence the development of vaccines and therapeutic agents. As various mutant SARS-CoV-2 viruses have been reported, it is urgent to provide a method capable of acting against not only wild-type viruses but also mutant viruses.

[0016] A rapid diagnostic test (RDT) is also referred to by various names such as “immunochromatographic analysis”, “rapid kit analysis”, and the like. A user can simply detect an analyte from a biological or chemical sample by the rapid diagnostic test. The rapid diagnostic test is a method capable of qualitatively and quantitatively testing analytes within a short time using the properties of biological or chemical materials that specifically adhere to each other.

[0017] The rapid diagnostic test is the most advanced assay kit among the detection methods developed until recently, in view of simplicity and quickness, and is usefully used to diagnose various disease-causing substances such as antibodies or antigens of infectious pathogens, cancer factors, heart disease markers, and the like.

[0018] There is no specific preventive agent, therapeutic agent, or diagnostic kit for coronaviruses including SARS-CoV-2, or SARS-CoV-1 and MERS-CoV which are likely to re-emerge. Accordingly, the present inventors have made efforts to develop a therapeutic antibody capable of acting against mutant viruses and coronaviruses that are likely to occur later.

[0019] Accordingly, the present applicant has conducted extensive studies, and as a result, developed an antibody capable of neutralizing not only wild-type COVID-19 and mutant COVID-19 viruses, but also viruses belonging to the family Coronaviridae, such as SARS or MERS, thereby completing the present invention.

[0056] Coronaviruses are RNA viruses belonging to the subfamily Coronavirinae of the family Coronaviridae, and are divided according to the host into four genera: alpha-, beta-, delta-, and gamma-coronaviruses. Not only human corona viruses but also mammalian coronaviruses found in cats, pigs, cattle, and bats mainly belong to the alpha- and beta-coronavirus genera, and most viruses infecting birds belong to the genus gamma-coronavirus. It is known that there are various coronavirus species, and coronaviruses cause both respiratory and digestive infectious diseases depending on the characteristics of the virus and on the host. Coronaviruses are viruses that cause respiratory illnesses of varying severity from the common cold to fatal pneumonia. Viruses belonging to the family Coronaviridae generally have a single-stranded, infectious, positive sense RNA genome with a length of 27 to 32 kb, and contain a cap at the 5′ end of the genome and a poly A tail at the 3′ end. Coronaviruses have an envelope, and contain major outer membrane proteins such as spike (S) protein and envelope (E) protein. The spike protein is involved in viral infection and pathogenicity, such as neutralizing antibody induction, receptor binding, and membrane fusion, and the envelope (E) protein is involved in morphogenesis of viral particles and extracellular release of the virus after infection.

[0057] Seven types of coronavirus are known to cause disease in humans, and infection with three types among them may cause even more severe or fatal pneumonia in humans. The three types that are fatal to humans include SARS-coronavirus-1 (SARS-CoV-1), which was identified as the cause of the 2002 severe acute respiratory syndrome outbreak which was a worldwide problem, MERS-coronavirus (MERS-CoV), which was identified as the cause of the 2012 Middle East respiratory syndrome outbreak, and the new coronavirus severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), which was first found in Wuhan, China in late 2019 and identified as the cause of coronavirus infection 2019 (COVID-19). Severe acute respiratory syndrome (SARS) coronavirus 2, SARS-CoV-2) is the cause of coronavirus infection 2019 (COVID-19), and is a novel coronavirus first found in Wuhan, China in late 2019.

[0058] SARS-coronavirus-1 (SARS-CoV-1) is a new infectious disease that has spread to countries worldwide, including Hong Kong, Singapore, and Canada, within a few months after its first outbreak in China in the winter of 2002, and the causative agent of SARS is SARS coronavirus-1. SARS-CoV-1 is presumed to have crossed the interspecies barrier from animals to infect humans by coronavirus variants that use animals as hosts. It is known that the main symptoms of SARS-CoV-1 are fever and cough, a sharp decrease in blood oxygen saturation, dyspnea, pneumonia, etc., and most of SARS-CoV-1 patients recover, but SARS-CoV-1 can be the cause of death in the elderly or children. Since there is no vaccine or therapeutic agent for prevention, it has been recommended to prescribe flu drugs, antiviral drugs, and the like.

[0059] MERS-coronavirus (MERS-CoV) was first detected in Jordan and Saudi Arabia in 2012, and most MERS-CoV infections occurred in Saudi Arabia, and occurred in people who traveled to the Middle East from other countries or worked in the Middle East. MERS-coronavirus is spread through close contact with MERS patients or through airborne droplets released by an infected person coughing or sneezing, and most people infected with MERS experience fever,

chills, muscle pain, and cough. So far, there is no MERS vaccine and therapeutic agent in Korea and other countries. For treatment of MERS-CoV, it is generally recommended to use drugs such as the immunomodulator interferon and the antiviral agent ribavirin or lopinavir. However, it has been reported that interferon and ribavirin cause side effects such as bone marrow function deterioration, anemia and viral mutations, and thus there are concerns about the safety thereof. In addition, co-administration of interferon and ribavirin showed a therapeutic effect against MERS in the monkey model, but it did not show a great effect on MERS patients in actual clinical practice, and thus there has been a need to develop a safer and more effective agent for treatment of MERS. In Korea, there has been no additional occurrence after the last occurrence of MERS-coronavirus infection, but MERS-coronavirus infection has continuously occurred in Middle Eastern countries, and thus it is necessary to prepare countermeasures against the re-introduction of MERS-coronavirus.

[0060] The World Health Organization (WHO) classifies SARS-coronavirus-2 (SARS-CoV-2) into six types based on amino acid changes due to differences in the gene sequence. SARS-CoV-2 was first classified into S and L types, and was then further divided into L, V, and G types, and G was subdivided into GH and GR, resulting in a total of six types: S, L, V, G, GH, and GR. At the beginning of the outbreak of COVID-19, S and V types were prevalent in Asian regions including Wuhan, China, and then different types were discovered in each continent, and the SARS-coronavirus-2 of the present invention includes these types. Among these, it has been reported that the GH type is likely to have high transmissibility. In Korea, based on the results of classifying genes collected from patients with coronavirus infection, most of them were found to be GH type, which is a variant of the G type prevalent in Europe and the United States, and this type is known to be highly transmissible. In particular, the G-type virus, in which the amino acid at position 614 of the spike protein, which plays an important role in the intracellular invasion of the virus, changed from aspartic acid (D) to glycine (G), has increased rapidly in Europe and the United States since March, and now appears in almost all regions, and the SARS-coronavirus-2 of the present invention includes the same. A recent report showed that more than 70 coronavirus variants occurred, among which 8 variants (D614G, etc.) having increased transmissibility, 10 variants (A841V, etc.) avoiding neutralizing antibodies, and 17 variants (I472V, etc.) on which plasma treatment effects are low, were identified, and the SARS-coronavirus-2 of the present invention includes these variants.

[0061] In one embodiment, the neutralizing binding molecule of the present invention may exhibit neutralizing activity against strains such as an S type (the amino acid at position 614 of the S protein is D), L type, V type, G type (the amino acid at position 614 of the S protein is G), GH type, or GR type, based on the amino acid mutation in SARS-coronavirus-2 (SARS-CoV-2), without being limited thereto. Examples of the SARS-CoV-2 virus S-type include, but are not limited to, a BetaCoV/Korea/KCDC03/2020 strain. Examples of the SARS-CoV-2 virus G-type include, but are not limited to, hCoV-19/South Korea/KUMC17/2020 strain. In one embodiment, the neutralizing binding molecule of the present invention may also exhibit neutralizing activity against a mutant virus having D614G mutation at amino acid position 614 of the spike protein of SARS-coronavirus-2 (SARS-CoV-2).

[0062] In one embodiment of the present invention, the neutralizing binding molecule of the present invention may have neutralizing activity against any one or more mutant viruses selected from the group consisting of the following mutant viruses 1) to 39), without being limited thereto. [0145] Coronaviruses can cause not only the common cold in humans, but also direct viral bronchitis or secondary bacterial bronchitis. Seven types of human coronavirus have been reported, such as human coronavirus 299E (HCoV-229E), human coronavirus OC43 (HCoV-OC43), human coronavirus NL63 (HCoV-NL63), human coronavirus HKU1 (HCoV-HKU1), Middle East respiratory syndrome coronavirus (MERS-CoV), severe acute respiratory syndrome coronavirus 1 (SARS-CoV-1), and SARS-coronavirus-2 (SARS-CoV-2). Infection with four types (HCoV-229E, HCoV-OC43, HCoV-NL63, and HCoV-HKU1) results in mild upper respiratory tract disease causing symptoms of the common cold, but three types (SARS-CoV-1, MERS-CoV, and SARS-CoV-2) can cause severe and fatal pneumonia. The human coronavirus that first occurred in China in the winter of 2002 is severe acute respiratory syndrome coronavirus 1 (SARS-CoV-1), which causes severe acute respiratory syndrome, and the main symptoms thereof are fever, malaise, muscle pain, headache, chills, etc., and cough and shortness of breath may appear. SARS-CoV-1 causes upper and lower respiratory tract infections. Currently, there is no fundamental treatment method for SARS-CoV-1, and an antibacterial agent against the causative agent of common pneumonia is administered. The main clinical symptoms of Middle East respiratory syndrome coronavirus (MERS-CoV) found in 2012 are fever, cough, and shortness of breath. Most MERS-CoV patients have severe acute respiratory tract disease (pneumonia), but some patients have mild acute upper respiratory tract disease or are asymptomatic. In particular, MERS-Cov has a high infection rate and poor prognosis in people with underlying diseases (diabetes, renal failure, chronic lung disease, or immunodeficiency disease). As of 2020, MERS-CoV outbreaks have been reported in about 27 countries. Currently, a vaccine for preventing MERS-CoV infection has not been developed worldwide, and a therapeutic agent for MERS-CoV has not been developed due to limited information on the disease.

[0146] In one embodiment of the present invention, the present invention is directed to binding molecules that are able to bind to and neutralize the coronavirus superfamily against which a preventive or therapeutic agent has not yet been developed, and the binding molecules of the present invention may also have binding affinity and/or neutralizing activity

against coronaviruses, including wild-type and mutant SARS-CoV-2, and/or SARS-CoV-1, and/or MERS-CoV.

[0157] In the present invention, CDRs of variable regions were determined through a conventional method using a system devised by Kabat et al. (see Kabat et al., Sequences of Proteins of Immunological Interest (5.sup.th), National Institutes of Health, Bethesda, MD. (1991)). The CDR numbering used in the present invention is determined using the Kabat method, but the present invention also encompasses binding molecules comprising CDRs determined through other methods such as an IMGT method, Chothia method, AbM method, or the like. For example, as shown in Table 2 below, as binding molecules comprising three light-chain CDR regions (LC CDR1, LC CDR2, and LC CDR3) contained in the light-chain (LC) variable region and three heavy-chain CDR regions (HC CDR1, HC CDR2, and HC CDR3) contained in the heavy-chain (HC) variable region, binding molecules comprising CDRs determined through a Kabat method, an IMGT method, a Chothia method and/or an AbM method are included within the scope of the present invention.

[0158] In one embodiment of the present invention, the binding molecule comprises any one binding molecule selected from the group consisting of binding molecules Nos. 1 to 190 shown in Table 2 below, or comprises a binding molecule derived therefrom. In Table 2 below, No. represents each binding molecule number.

[0159] In another embodiment of the present invention, the binding molecule may be any one selected from the group consisting of binding molecule Nos. 2, 3, 12, 15, 16, 18, 19, 20, 22, 23, 24, 26, 31, 32, 33, 34, 37, 43, 45, 48, 50, 51, 53, 54, 55, 56, 59, 60, 61, 66, 69, 74, 75, 76, 81, 82, 83, 85, 86, 87, 93, 94, 95, 96, 98, 102, 103, 104 and 108 among the binding molecules shown in Table 2 below, or may be a binding molecule comprising a sequence derived therefrom.

[0160] In another embodiment of the present invention, the binding molecule may be any one selected from the group consisting of binding molecule Nos. 2, 32, 59, 95, 102 and 103 among the binding molecules shown in Table 2 below, or may be a binding molecule comprising a sequence derived therefrom.

[0161] In another embodiment of the present invention, the binding molecule may be any one selected from the group consisting of binding molecule Nos. 32, 33, 34, 37, 45, 48, 53, 54, 59, 61 and 81 among the binding molecules shown in Table 2 below, or may be a binding molecule comprising a sequence derived therefrom.

[0162] In another embodiment of the present invention, the binding molecule may be any one selected from the group consisting of binding molecule Nos. 32, 34, 37, 45 and 54 among the binding molecules shown in Table 2 below, or may be a binding molecule comprising a sequence derived therefrom.

[0163] In another embodiment of the present invention, the binding molecule may be any one selected from the group consisting of binding molecule Nos. 32 and 54 among the binding molecules shown in Table 2 below, or may be a binding molecule comprising the same.

[0164] In another embodiment of the present invention, the binding molecule may be the binding molecule of binding molecule No. 32 among the binding molecules shown in Table 2 below.

The antibody may be a monoclonal antibody, preferably a chimeric antibody, a humanized antibody, or a human antibody, without being limited thereto. The antigen-binding fragment may be Fab, F(ab′), F(ab′)2, Fv, dAb, Fd, a single-chain antibody fragment (scFv), scFv-Fc, a complementarity-determining region

(CDR) fragment, a bivalent single-chain antibody fragment, a single-chain phage antibody fragment, a diabody, a triabody, or a tetrabody, without being limited thereto. [1061] An embodiment of the present invention provides scFv-Fc that binds to the S protein of SARS-CoV-2. Another embodiment of the present invention provides a fully human antibody (full IgG) that binds to the S protein of SARS-CoV-2.
[1062] An embodiment of the present invention provides scFv-Fc that binds to the S protein of SARS-CoV-1. Another embodiment of the present invention provides a fully human antibody (full IgG) that binds to the S protein of SARS-CoV-1.
[1063] An embodiment of the present invention provides scFv-Fc that binds to the S protein of MERS-CoV. Another embodiment of the present invention provides a fully human antibody (full IgG) that binds to the S protein of MERS-CoV.
[1064] In the present invention, the binding molecules include those that exist in the human body and those that are not present in the human body but are wholly or partially artificially produced. In particular, the binding molecule of the present invention may be one that is wholly or partially artificially produced. Wholly or partially artificially produced examples include, but are not limited to, those produced in vitro or isolated, those produced by mammalian cell culture, those artificially produced by transformed cells, or those artificially produced through shuffling recombination of genetic information of light-chain and/or heavy-chain variable regions of the antibody.
[1065] As used herein, the term “antibody” is used in the broadest sense, and particularly includes an intact monoclonal antibody, a polyclonal antibody, a multispecific antibody (e.g., a bispecific antibody) formed from two or more intact antibodies, and an antibody fragment that shows a desired biological activity. The antibody is a protein that is produced by an immune system capable of recognizing and binding to a specific antigen. Structurally, the antibody generally has a Y-shaped protein comprising four amino acid chains (two heavy chains and two light chains). Each antibody generally has two regions (a variable region and a constant region). The variable region, which is located at the ends of the arms of the Y, binds to and interacts with a target antigen. The variable region includes a complementarity-determining region (CDR) that recognizes and binds to a specific binding site on a specific antigen. The constant region, which is located at the tail of the Y, is recognized by the immune system and interacts therewith. The target antigen generally has a plurality of binding sites called epitopes, which are recognized by CDRs on antibodies. Respective antibodies that specifically bind to different epitopes have different structures. Therefore, a single antigen may have at least one antibody corresponding thereto.
[1066] Moreover, the present invention includes functional variants of the binding molecule. Binding molecules are considered to be functional variants of the binding molecule of the present invention so long as the variants are capable of competing with the binding molecule of the present invention in order to specifically bind to coronavirus or to an S protein thereof and also have neutralizing activity against coronavirus. Such functional variants include, but are not limited to, derivatives that are substantially similar in primary structural sequence, and examples thereof include in-vitro or in-vivo modifications, chemicals and/or biochemicals, that are not found in the parental monoclonal antibody of the present invention. Such modifications include, for example, acetylation, acylation, covalent attachment of a nucleotide or nucleotide derivative, covalent attachment of a lipid or lipid derivative, cross-linking, disulfide bond formation, glycosylation, hydroxylation, methylation, oxidation, pegylation, proteolytic processing, phosphorylation, and the like. Alternatively, the functional variants may be antibodies comprising an amino acid sequence containing one or more substitutions, insertions, deletions or combinations thereof of one or more amino acids compared to the amino acid sequence of the parental antibody. Furthermore, the functional variants may comprise truncated forms of the amino acid sequence at either or both the amino or carboxyl termini. The functional variants of the present invention may have the same or different, either higher or lower, binding affinities compared to the parental antibody of the present invention but are still capable of binding to coronavirus or an S protein thereof. For instance, the amino acid sequences of the variable regions, including, but not limited to, framework regions, hypervariable regions, in particular, the light-chain or heavy-chain complementarity-determining regions (CDRs), may be modified. Generally, the light chain or heavy chain variable regions comprise three hypervariable regions, comprising three CDRs, and more conserved regions, the so-called framework regions (FRs). The hypervariable regions comprise amino acid residues from CDRs and amino acid residues from hypervariable loops. Functional variants falling within the scope of the present invention may have about 50% to 99%, about 60% to 99%, about 80% to 99%, about 90% to 99%, about 95% to 99%, or about 97% to 99% amino acid sequence identity with the parental antibody defined herein. Computer algorithms such as Gap or Bestfit known to a person skilled in the art may be used to optimally align amino acid sequences to be compared and to define similar or identical amino acid residues. The functional variants may be obtained by altering the parental antibodies or parts thereof by general molecular biology methods known in the art, including PCR, oligonucleotide-directed mutagenesis, and site-directed mutagenesis, or by organic synthesis processes, without being limited thereto.
[1067] The present invention also provides an immunoconjugate in which at least one tag is additionally conjugated to the binding molecule. In one embodiment, a drug may be additionally conjugated to the binding molecule. Specifically, the binding molecule according to the present invention may be used in the form of antibody-drug conjugates comprising a drug conjugated thereto. The use of antibody-drug conjugates (ADCs), i.e. immunoconjugates, for the local delivery of drugs, allows targeted delivery of the drug moiety to infected cells, because administration of unconjugated drug agents may result in unacceptable levels of toxicity to normal cells. The maximal efficacy and minimal toxicity of ADC can be achieved by increasing the selectivity of polyclonal and monoclonal antibodies (mAbs) as well as drug-linking and drug-releasing properties.
[1068] Conventional means of attaching, i.e., linking through covalent bonds, a drug moiety to an antibody generally leads to a heterogeneous mixture of molecules where the drug moieties are attached at a number of sites on the antibody. For

example, cytotoxic drugs have typically been conjugated to antibodies through the often-numerous lysine residues of an antibody, thereby generating a heterogeneous antibody-drug conjugate mixture. Depending on reaction conditions, the heterogeneous mixture typically contains a distribution of antibodies with from 0 to about 8 or more, attached to drug moieties. In addition, each subgroup of conjugates with a particular integer ratio of drug moieties to antibody is a potentially heterogeneous mixture where the drug moiety is attached at various sites on the antibody. Antibodies are large, complex and structurally diverse biomolecules, often with many reactive functional groups. Their reactivities with linker reagents and drug-linker intermediates are dependent on factors such as pH, concentration, salt concentration, and co-solvents.

[1069] Another embodiment of the present invention provides a nucleic acid molecule encoding the binding molecule.

[1070] The nucleic acid molecule of the present invention includes any nucleic acid molecule in which the amino acid sequence of the antibody provided in the present invention is translated into a polynucleotide sequence as known to those skilled in the art. Thus, various polynucleotide sequences may be produced using an ORF (open reading frame), and may also be included within the range of the nucleic acid molecule of the present invention.

[1072] The expression vector may be any one expression vector selected from the group consisting of a MarEx vector (see Korean Patent No. 10-1076602), which is an expression vector available from Celltrion, and a commercially widely useful pCDNA vector, F, R1, RP1, Col, pBR322, ToL, and Ti vector; a cosmid; phages, such as lambda, lambdoid, M13, Mu, p1 P22, Qμ, T-even, T2, T3, T7, etc.; and plant viruses, without being limited thereto. Any expression vector known to those skilled in the art may be used in the present invention, and the expression vector may be selected depending on the properties of the host cell of interest. The introduction of the vector into the host cell may be performed by calcium phosphate transfection, viral infection, DEAE-dextran-mediated transfection, lipofectamine transfection, or electroporation, without being limited thereto, and those skilled in the art may adopt an introduction process suitable for the expression vector used and the host cell. For example, the expression vector may contain at least one selection marker, without being limited thereto, and even when a vector not containing a selection marker is used, selection is possible depending on whether or not the product is capable of being obtained. Choosing the selection marker depends on the host cell of interest, and is performed using any method known to those skilled in the art, and thus is not critical to the present invention.

[1073] In order to facilitate the purification of the binding molecule of the present invention, a tag sequence may be inserted into the expression vector and thus fused therewith. Examples of the tag include, but are not limited to, a hexa-histidine tag, a hemagglutinin tag, a myc tag or a flag tag, and any tag known to those in the art, which facilitates purification, may be used in the present invention.

[1112] Hereinafter, the terms used in the present invention will be defined as follows.

[1113] As used herein, the term “binding molecule” refers to intact immunoglobulins, including monoclonal antibodies, such as chimeric, humanized or human monoclonal antibodies, or antigen-binding fragments, which are immunoglobulins that bind to antigens. For example, the term indicates a variable domain, enzyme, receptor or protein comprising an immunoglobulin fragment that competes with the intact immunoglobulin in order to bind to a spike protein on SARS-CoV-2. Regardless of the structure, an antigen-binding fragment binds to the same antigen that is recognized by the intact immunoglobulin. The antigen-binding fragment may comprise a peptide or polypeptide comprising an antibody amino acid sequence comprising 2 or more contiguous amino acid residues, 20 or more contiguous amino acid residues, 25 or more contiguous amino acid residues, 30 or more contiguous amino acid residues, 35 or more contiguous amino acid residues, 40 or more contiguous amino acid residues, 50 or more contiguous amino acid residues, 60 or more contiguous amino acid residues, 70 or more contiguous amino acid residues, 80 or more contiguous amino acid residues, 90 or more contiguous amino acid residues, 100 or more contiguous amino acid residues, 125 or more contiguous amino acid residues, 150 or more contiguous amino acid residues, 175 or more contiguous amino acid residues, 200 or more contiguous amino acid residues, or 250 or more contiguous amino acid residues.

[1114] As used herein, the term “antigen-binding fragment” includes Fab, F(ab′), F(ab′)2, Fv, dAb, Fd, a complementarity-determining region (CDR) fragment, a single-chain antibody fragment (scFv), a bivalent single-chain antibody fragment, a single-chain phage antibody fragment, a diabody, a triabody, a tetrabody, a polypeptide that contains at least one fragment of an immunoglobulin that is sufficient to confer specific antigen binding to the polypeptide, etc. The above fragment may be produced synthetically or by enzymatic or chemical cleavage of intact immunoglobulins, or may be produced using a genetic engineering method by a recombinant DNA technique. Such production methods are well known in the art.

[1115] As used herein, the term “pharmaceutically acceptable excipient” refers to any inert substance that is combined with an active molecule such as a drug, agent, or antibody for preparing an agreeable or convenient dosage form. The pharmaceutically acceptable excipient is an excipient that is non-toxic, or at least of which the toxicity is acceptable for its intended use, to recipients at the dosages and concentrations employed and is compatible with other ingredients of the formulation comprising the drug, agent or binding molecule.

[1116] As used herein, the term “therapeutically effective amount” refers to an amount of the binding molecule of the present invention that is effective for prevention or treatment before or after exposure to coronavirus. In one embodiment of the present invention, the therapeutically effective amount may be, for example, 0.1 to 300 mg/kg.

[1117] As used herein, the term “culturing” means the in vitro maintenance, differentiation, growth, proliferation and/or reproduction of cells in a medium under suitable conditions.

[1118] As used herein, the term “comprises”, “comprising”, “includes” or “including” means that it may further comprise other components in addition to the corresponding component, and is different from the term “consisting of” that excludes further comprising other additional components.

[1119] The features described herein may be used in combination, and the fact that the features are set forth in different dependent claims of the claims does not indicate that they cannot be used in combination.

MODE FOR INVENTION

[1120] Hereinafter, the present invention will be described in detail with reference to examples. However, the following examples are merely illustrative of the content of the present invention, and the scope of the invention is not limited by the examples. Documents cited herein are incorporated herein by reference.

Example 1: Isolation of PBMCs from Blood of Patients Who Recovered from SARS-CoV-2

[1121] Blood donors were people (Korean adults) who were confirmed to have been infected with SARS-CoV-2 in 2020 and no longer exhibited viruses as a result of treatment, and the donor selection and blood collection processes were performed under the approval of the Institutional Review Board (IRB). After donor selection, about 30 ml of whole blood was collected, and PBMCs (peripheral blood mononuclear cells) were isolated using a Ficoll-Paque™ PLUS (GE Healthcare) method. The isolated PBMCs were washed twice with a phosphate buffer solution and then adjusted to a concentration of 1×10.sup.7 cells/ml in a freezing medium (RPMI:FBS:DMSO=5:4:1) and stored in a liquid nitrogen tank.

Example 2: Production of Antibody-Displayed Phage Library

[1122] Total RNA was extracted from the PBMCs (isolated in Example 1) using a TRIzol reagent (Invitrogen), and then cDNA was synthesized therefrom using a SuperScript™ III First-Strand cDNA synthesis system (Invitrogen, USA).

[1123] Production of the antibody library from the synthesized cDNA was performed with reference to the related literature (Barbas C. et. al. Phage Display: A Laboratory Manual. 2001. CSHL Press). Briefly, light-chain and heavy-chain variable regions of the antibody were amplified from the synthesized cDNA by a PCR (polymerase chain reaction) method using high-fidelity Taq polymerase (Roche) and a degenerative primer set (IDT). The isolated light-chain and heavy-chain variable-region fragments were made into an scFv gene by an overlap PCR method so as to be connected as one sequence in random combination, and the scFv gene was amplified, cleaved with restriction enzymes, and then isolated using 1% agarose gel electrophoresis and a gel extraction kit (Qiagen). A phage vector was cleaved with the same restriction enzymes, isolated, and mixed with the scFv gene, and T4 DNA ligase (New England Biolabs) was added thereto. The resulting mixture was allowed to react at 16° C. for 12 hours or more. The resulting reaction solution was mixed with ER2738 competent cells, and then transformed into the cells by an electroporation process. The transformed ER2738 cells were subjected to shaking culture, and then a VCSM13 helper phage (Agilent Technologies) was added thereto, followed by culturing for 12 hours or more.

Example 3: Selection Using Phage Enzyme Immunoassay

[1124] The phage library culture prepared in Example 2 was centrifuged to remove the host cells, and then 4% PEG and 0.5 M NaCl were added thereto. The phage was precipitated by centrifugation and the supernatant was removed. The precipitated phage was diluted with 1% BSA/TBS to afford a phage library, and then panning was independently performed through association to and dissociation from various SARS-CoV-2 spike proteins (S1, S2, S1+S2), SARS-CoV-1 spike proteins or MERS-CoV spike proteins, thereby isolating an scFv-phage having ability to bind to SARS-CoV-2, SARS-CoV-1 or MERS-CoV spike proteins. For example, the phage library was added to an ELISA plate to which an S2 domain (residues S686 to P1213 on S protein), which is a portion of the SARS-CoV-2 S protein, was attached, followed by reaction at room temperature for 2 hours. The reaction solution was removed, and then the ELISA plate was washed with PBS containing 0.05% Tween 20. Next, the scFv-phage bound to the antigen was detached by adding 60 μl of 0.1 M glycine-HCl (pH 2.2), and neutralized using 2M Tris (pH 9.1). The neutralized scFv-phage was infected into ER2738 cells, and then incubated with helper phage, and used for subsequent panning. A portion of the infected ER2738 was spread on an LB plate before the addition of the helper phage, and a colony was obtained the next day.

[1125] The colonies, formed in each panning round, were shake-cultured in a culture medium in a 96-well deep well plate (Axygen), and when the OD.sub.600 reached 0.7 or more, helper phage was added thereto, followed by shaking culture at 37° C. for 12 hours or more. The culture was centrifuged, the host cells were removed, and the supernatant containing the scFv-phage was collected.

[1126] The collected scFv-phage supernatant was diluted at 1:1 with 6% BSA/PBS, and then added to each well of a 96-well microtiter plate, which has been adsorbed with SARS-CoV-2 S proteins and then blocked, and each well was incubated at 37° C. for 2 hours. Each well was washed three times with PBS containing 0.05% Tween 20, and then incubated with an anti-M13 antibody labeled with HRP (horseradish peroxidase) 37° C. for 1 hour. Each well was washed three times with PBS containing 0.05% Tween 20, and then ABTS (2,2′-azinobis[3-ethylbenzothiazoline-6-sulfonic acid]-diammonium salt) was added thereto, and the absorbance at 405 nm was measured, thereby selecting scFv-phages having ability to bind to SARS-CoV-2 S antigen proteins.

Example 4: Evaluation of Neutralizing Activity of scFv-Fc Antibody Fragment Against SARS-CoV-2

[1127] For the scFv-phages selected in Example 3, DNA was obtained through shaking culture of colonies, and then sequences for antibody variable regions were analyzed. Among them, scFv-phages, selected by excluding clones with overlapping amino acid sequences, were cloned into vectors in the form of an scFv antibody fragment (scFv-Fc) in order to evaluate the expression levels of candidate antibodies in animal cell lines. The scFv-phages were transfected into CHO cells using a transfection reagent and expressed therein, and using the culture of the cells, the 190 scFv-Fc antibody fragments were evaluated against the Korean isolate SARS-CoV-2 virus S type (betaCoV/Korea/KCDC03/2020; NCCP43326) by CPE (cytopathic effect) assay. The 190 selected antibody fractions are shown in Tables 1 and 2.

[1128] For CPE assay, each antibody sample was diluted, mixed with an equal volume of 100TCID50 virus, incubated at 37° C. for 30 minutes, and infected into the VERO.E6 cell line, and viable cells were analyzed. After 4 days of incubation in an incubator at 37° C. under 5% CO.sub.2, the neutralizing activity of each antibody fragment was evaluated by analyzing viable cells. Two wells at one concentration were independently analyzed, and the neutralizing activity (%) of the antibody was expressed as 100% when the cells in the two wells were variable. 50% indicates a case in which the cells in only one well were viable, and 0% indicates a case in which the cells in the two wells were not viable.

[1129] As a result of the analysis, as shown in Table 3 below, antibody fragments having neutralizing activity were identified. No. in Table 3 below refers to the same binding molecule as the No. of each binding molecule shown in Tables 1 and 2 above. The positive control antibody in Table 3 below is Celltrion's CT-P59 COVID-19 neutralizing antibody (antibody No. 139 disclosed in Korean Patent No. 10-2205028).

Example 5: Evaluation of Binding Affinity of Antibody after Conversion into Fully Human Antibody (Full IgG)

[1130] The selected antibody fragments (scFv-Fc) confirmed to have neutralizing activity in Example 4 above were converted into fully human antibodies (full IgG), and antibody-containing cultures were prepared according to the method of Example 4. The binding affinity (equilibrium dissociation constant, K.sub.D) of each fully human antibody to SARS-CoV-2 RBD was evaluated by biolayer interference (BLI) assay using Octet. As a result of analysis, it was confirmed that 11 fully human antibodies had excellent binding affinity to the SARS-CoV-2 virus surface protein (RBD) as shown in Table 4 below. No. in Table 4 below refers to the same binding molecule as the No. of each binding molecule shown in Tables 1 and 2 above.

Example 6: Evaluation of Neutralizing Activity of Fully Human Antibody (Full IgG)

6-1. Evaluation (1) of Neutralizing Activity of Fully Human Antibody (Full IgG)

[1131] The 11 fully human antibodies (full IgGs) selected based on their binding affinity to the SARS-CoV-2 S (RBD) protein and their expression level in Example 5 were evaluated for neutralizing activity against the Korean isolate SARS-CoV-2 virus GR type (hCoV-19/South Korea/KUMC17/2020) using a PRNT (plaque reduction neutralization test) method.

[1132] For PRNT, each antibody sample was diluted (10 concentrations, obtained through 1/4 serial dilution from 1 ng/ml, and 11 concentrations, obtained through 1/2 serial dilution from 0.5 ng/1l), mixed with an equal volume of a virus (0.05 MOI), incubated at 37° C. for 2 hours, and then infected into VERO.E6 cells, followed by plaque assay. After incubation in a 5% CO.sub.2 incubator at 37° C. for 60 hours, the neutralizing activity of each antibody sample was evaluated by staining with crystal violet and comparatively analyzing the number of formed plaques. The neutralizing activity (ng/ml) of each antibody is an average value obtained from the results of the neutralizing activity evaluation performed in duplicate, and was expressed as the IC.sub.50 value of the antibody-treated group. Here, the IC.sub.50 value is the antibody concentration at which the antibody exhibits 50% of the neutralizing activity against the virus. In Table 5 below, a lower value indicates the better neutralizing activity.

[1133] As a result of analysis, as shown in Table 5 below, fully human antibodies (full IgG) having excellent neutralizing activity were confirmed. In Table 5 below, No. refers to the same binding molecule as the No. of each binding molecule shown in Tables 1 and 2.

[1134] 6 fully human antibodies (full IgGs), selected based on antibody characteristics such as antibody expression levels, were additionally evaluated for neutralizing activity against the SARS-CoV-2 GR type virus using a PRNT (plaque reduction neutralization test) method.

[1135] As a result of analysis, it was confirmed that the antibodies had neutralizing activity as shown in Table 6 below. In Table 6 below, No. refers to the same binding molecule as the No. of each binding molecule shown in Tables 1 and 2. The positive control antibody in Table 6 below is Celltrion's CT-P59 COVID-19 neutralizing antibody.

[1139] As a result of analysis, it was confirmed that the antibodies had neutralizing activity as shown in Table 8 below. In Table 8 below, No. refers to the same binding molecule as the No. of each binding molecule shown in Tables 1 and 2 above. In Table 8 below, the positive control antibody against SARS-CoV-1 is CR3022 (Xiaolong Tian et al., Emerg Microbes Infect. 2020 Feb. 17; 9(1):382-385), and the positive control antibody against MERS-CoV is Celltrion's CT-P38 MERS neutralizing antibody (antibody 5 disclosed in Table 7 of Korean Patent Application Publication No. 10-2019-0093114).

6-7. Evaluation of Neutralizing Activity of Antibody No. 32

[1144] Antibody No. 32 (corresponding to No. 32 in Tables 1 and 2), which is a fully human antibody (full IgG) selected based on its binding affinity to the SARS-CoV-2 S (RBD) protein and expression level and its neutralizing activity against the wild-type SARS-CoV-2 virus, was evaluated for neutralizing activity against the mutant virus strain from South Africa (hCoV-19/South Korea/KDCA0463/2020) by a PRNT (plaque reduction neutralization test) method.

[1145] For PRNT, the antibody sample was diluted (11 concentrations obtained through 1/2 serial dilution from 1 ng/μl), mixed with an equal volume of a virus (0.05 MOI), incubated at 37° C. for 2 hours, and then infected into VERO.E6 cells, followed by plaque assay. After incubation in a 5% CO.sub.2 incubator at 37° C. for 60 hours, the neutralizing activity of the antibody sample was evaluated by staining with crystal violet and comparatively analyzing the number of formed plaques. The neutralizing activity (ng/ml) of the antibody is an average value obtained from the results of the neutralizing activity evaluation performed in duplicate, and was expressed as the IC.sub.50 value and IC.sub.90 value of the antibody-treated group. Here, the IC.sub.50 value is the antibody concentration at which the antibody exhibits 50% of the neutralizing activity against the virus, and the IC.sub.90 value is the antibody concentration at which the antibody exhibits 90% of the neutralizing activity against the virus. In Table 11 below, a lower value indicates the better neutralizing activity.

[1146] As a result of analysis, it was confirmed that antibody No. 32 had neutralizing activity against the mutant virus strain from South Africa as shown in Table 11 below.

6-8. Evaluation of Neutralizing Activity of Antibody No. 32 Against SARS-CoV-2 Mutant Pseudoviruses

[1147] A test was conducted to evaluate the neutralizing activities of antibody No. 32 against SARS-CoV-2 spike D614 and 50 prepared SARS-CoV-2 spike mutant pseudoviruses. The SARS-CoV-2 spike mutant pseudoviruses were prepared with reference to a portion of the epitope of the CT-P59 (Regdanvimab) antibody and the mutant viruses published in papers (A. Baum et al., Science, 2020 Aug. 21; 369(6506):1014-1018., Korber et al., 2020, Cell 182, 812-827., and Wang et al., 2021, doi: 10.1038/s41586-021-03398-2.). The amount of each mutant pseudovirus was fixed at 1.73×10.sup.7 copies, and the antibody was diluted in 10 steps of 3-fold dilutions to the highest concentration of 100 ng/mL. As a result of conducting a neutralization activity test using each mutant pseudovirus and each antibody dilution, it was confirmed that the antibody had neutralizing activity as shown in Table 12 below.

[1148] In Table 12 below, each mutation position was numbered from the N-terminus of the coronavirus spike protein (NCBI accession number: YP_009724390.1, SEQ ID NO: 1,521). In addition, the position of each mutation in UK mutant

Example 7. Evaluation of Binding Affinity and Mechanism of Action of Fully Human Antibody (Full IgG)

[1153] The binding affinity (antibody No. 32 and No. 54) and mechanism of action (antibody No. 32) of the antibodies (full IgG), selected in Examples 5 and 6, to SARS-CoV-2 RBD mutant proteins, were evaluated by performing Octet analysis.

[1154] SARS-CoV-2 virus can initiate infection of human cells by binding of the surface protein (RBD) thereof to the human receptor (ACE2). Thus, the mechanism of action of antibody No. 32 (full IgG) was evaluated by performing biolayer interference (BLI) assay using Octet. As a result of analysis, it was confirmed that the antibodies had excellent binding affinity even to mutant proteins of the SARS-CoV-2 virus surface protein (RBD) as shown in Table 17 below, and

that the binding of the SARS-CoV-2 virus surface protein (RBD) to the human receptor (ACE2) was completely inhibited by antibody No. 32 (full IgG) as shown in FIG. **1**.

Example 8. Evaluation of Neutralizing Activity of Fully Human Antibody (Full IgG) Against SARS-CoV-2 Virus Through Animal Experiment

8-1. Experiment for Evaluation of Preventive Efficacy in Mice

[1155] Using TG mice (B6.Cg-Tg(K18-ACE2)2Prlmn/J [Stock No: 034860 K18-hACE2] from The Jackson Laboratory) as an animal model that is naturally infected with SARS-CoV-2 virus and shows clinical symptoms and lesions similar to those in humans, an experiment was conducted as follows in order to evaluate the in-vivo preventive efficacy of antibody No. 32 and No. 54.

[1156] Mice were divided into a total of 10 groups, including a non-infected group, an infected group, and administered groups (1 mg/kg or 10 mg/kg CT-P59, 1 mg/kg or 10 mg/kg antibody No. 32, 1 mg/kg or 10 mg/kg antibody No. 54, and 1 mg/kg or 10 mg/kg antibody No. 32+antibody No. 54 cocktail). The non-infected group consisted of 3 mice, and the infected group and the administered groups consisted of 6 mice per group. 24 hours after administration of DPBS or 1 mg/kg or 10 mg/kg of each antibody to each group, 1×10.sup.5 PFU/50 μL of SARS-CoV-2 virus (NMC-nCoV02) was inoculated into the nasal cavity, and observation was performed for a maximum of 6 days. Additionally, the body weight of each mouse in each group was evaluated before viral inoculation and daily for 6 days after viral inoculation. In order to measure the virus titer in the tissue, the mice were sacrificed on days 3 and 6 after viral inoculation, and the lung tissue and nasal lavage fluid were obtained therefrom. The virus titer of each tissue was measured through plaque assay using Vero cells.

[1157] As a result, antibody No. 32 (1 and 10 mg/kg) and antibody No. 54 (10 mg/kg) showed non-inferiority in terms of body weight change compared to CT-P59. A low dose (1 mg/kg) of antibody No. 54 showed significantly lower results in terms of body weight change compared to CT-P59 and antibody No. 32 (FIG. **2***a*).

[1158] The results of measuring the virus titer in the lungs by plaque assay are as follows. A high dose (10 mg/kg) of antibody No. 32 antibody and a high dose (10 mg/kg) of the cocktail of antibody No. 32 and antibody No. 54 showed the best preventive efficacy because the virus was not detected from day 3. On day 6, all of the antibody-administered groups showed preventive efficacy (FIG. **2***b*).

[1159] In addition, the results of measuring the viral titer in the nasal lavage fluid by plaque assay are as follows. On day 3, there was no difference in preventive efficacy between the low-dose (1 mg/kg) groups. Only the antibody No. 32+antibody No. 54 cocktail group showed the best preventive efficacy in comparison between the low-dose (1 mg/kg) groups because the virus was not detected on day 6. The high dose (10 mg/kg) showed preventive efficacy on day 6 in all of the administered groups (FIG. **2***c*).
