### LIGHT-EMITTING DEVICE

#### Abstract

A light-emitting device includes: a base having an upper surface; one or more semiconductor laser elements disposed on the upper surface and configured to emit light in a first direction in a top view; one or more reflecting members spaced from the one or more semiconductor laser elements in the first direction in a top view; and a lens member having one or more lens sections through which light reflected by the one or more reflecting members passes, the lens member being fixed to the base and positioned above the one or more semiconductor laser elements and the one or more reflecting members. In a top view, at least a portion of a first of the one or more reflecting members and an emitting surface of a first of the one or more semiconductor laser elements is disposed in a region inward of an outer edge of a first of the one or more lens sections.

## Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS [0001] The present application is a continuation of U.S. patent application Ser. No. 18/394,233, filed on Dec. 22, 2023, which is a continuation of U.S. patent application Ser. No. 18/298,784, filed on Apr. 11, 2023 (now U.S. Pat. No. 11,892,155), which is a continuation of U.S. patent application Ser. No. 17/864,018, filed on Jul. 13, 2022 (now U.S. Pat. No. 11,655,958), which is a continuation of U.S. patent application Ser. No. 17/185,640, filed on Feb. 25, 2021 (now U.S. Pat. No. 11,428,382), which is a continuation of U.S. patent application Ser. No. 16/297,415, filed on Mar. 8, 2019 (now U.S. Pat. No. 11,149,917), which is a continuation of U.S. patent application Ser. No. 15/157,897, filed on May 18, 2016 (now U.S. Pat. No. 10,267,483), which claims priority to Japanese Patent Application No. 2015-103264, filed on May 20, 2015, and Japanese Patent Application No. 2016-051530, filed on Mar. 15, 2016. The entire disclosures of these applications are incorporated herein by reference.

## BACKGROUND

[0002] The present disclosure relates to a light-emitting device.

[0003] A light source device that collimates light emitted from a plurality of light sources with a collimator lens array is known (Japanese Patent Application Laid-open No. 2014-102367).

[0004] However, in the conventional light source device described above, respective lens elements constituting the collimator lens array have a plurality of curvatures in accordance with sectional shapes of laser beams incident to the respective lens elements. Therefore, when the collimator lens array is mounted even only slightly rotated from a prescribed direction, there is a risk that a significant deviation may occur in a positional relationship between the light sources and the lens

elements and, consequently, an intensity distribution of light emitted from the collimator lens array may change.

## SUMMARY

[0005] The problem described above can be solved by certain embodiments of the present invention. In one embodiment, a light-emitting device includes: a substrate; a lens array having a plurality of lens sections in a matrix pattern; and a plurality of semiconductor laser elements arranged on the substrate, wherein the plurality of semiconductor laser elements respectively emit a laser beam, each laser beam has a beam shape with a greater width in a column direction than in a row direction on a light incident surface of each of the plurality of lens sections, and the plurality of lens sections have an inter-vertex distance in the row direction that is smaller than both a maximum outer diameter of each of the lens sections and an inter-vertex distance in the column direction and have a same curvature in the row direction and the column direction.

[0006] According to the light-emitting device described above, a light-emitting device can be provided in which, even when the lens array is mounted slightly rotated from a prescribed direction, a significant deviation is less likely to occur in a positional relationship between a light sources and a lens element and intensity distribution of light emitted from the lens array is less susceptible to change.

---

## Description

### BRIEF DESCRIPTION OF THE DRAWINGS

[0007] FIG. 1A is a schematic plan view of a light-emitting device according to a first embodiment;  
[0008] FIG. 1B is a sectional view taken along A-A in FIG. 1A;  
[0009] FIG. 1C is a sectional view taken along B-B in FIG. 1A;  
[0010] FIG. 1D is a sectional view taken along C-C in FIG. 1A;  
[0011] FIG. 2A is a schematic plan view of a substrate;  
[0012] FIG. 2B is a sectional view taken along D-D in FIG. 2A;  
[0013] FIG. 2C is a sectional view taken along E-E in FIG. 2A;  
[0014] FIG. 3A is a schematic plan view of a lens array;  
[0015] FIG. 3B is a sectional view taken along F-F in FIG. 3A;  
[0016] FIG. 3C is a sectional view taken along G-G in FIG. 3A;  
[0017] FIG. 3D is a sectional view taken along H-H in FIG. 3A;  
[0018] FIG. 4A is a schematic plan view of semiconductor laser elements arranged on a substrate;  
[0019] FIG. 4B is a sectional view taken along I-I in FIG. 4A;  
[0020] FIG. 4C is a sectional view taken along J-J in FIG. 4A;  
[0021] FIG. 4D is a diagram showing an enlargement of a portion enclosed by a dashed line in FIG. 4C;  
[0022] FIG. 5A is a schematic plan view of a sealing member;  
[0023] FIG. 5B is a sectional view taken along K-K in FIG. 5A;  
[0024] FIG. 5C is a sectional view taken along L-L in FIG. 5A;  
[0025] FIG. 6A is a schematic plan view of a light-emitting device according to a second embodiment;  
[0026] FIG. 6B is a sectional view taken along M-M in FIG. 6A;  
[0027] FIG. 6C is a sectional view taken along N-N in FIG. 6A;  
[0028] FIG. 6D is a sectional view taken along O-O in FIG. 6A;  
[0029] FIG. 7 is a schematic plan view of a light-emitting device according to a third embodiment;  
and  
[0030] FIG. 8 is a schematic plan view of a light-emitting device according to a fourth embodiment.

## DETAILED DESCRIPTION

### Light-Emitting Device According to First Embodiment

[0031] FIG. 1A is a schematic plan view of a light-emitting device according to a first embodiment. In addition, FIG. 1B is a sectional view taken along A-A in FIG. 1A, FIG. 1C is a sectional view taken along B-B in FIG. 1A, and FIG. 1D is a sectional view taken along C-C in FIG. 1A. In FIG. 1A, a semiconductor laser element **30** and the like that are arranged below a top left lens section are transparently shown in order to facilitate understanding. As shown in FIGS. 1A to 1D, a light-emitting device **1** according to the first embodiment is an light-emitting device including: a substrate **10**; a lens array **20** having a plurality of lens sections **22** in a matrix pattern; and a plurality of semiconductor laser elements **30** arranged on the substrate **10**, wherein the plurality of semiconductor laser elements **30** respectively emit a laser beam, each laser beam has a beam shape with a greater width in a column direction than in a row direction on a light incident surface LA of each of the plurality of lens sections **22**, and the plurality of lens sections **22** have an inter-vertex distance PX in the row direction that is smaller than both a maximum outer diameter E of each of the lens sections **22** and an inter-vertex distance PY in the column direction and has a same curvature in the row direction and the column direction. An orderly description will be given below.

#### Substrate **10**

[0032] FIG. 2A is a schematic plan view of a substrate. FIG. 2B is a sectional view taken along D-D in FIG. 2A. FIG. 2C is a sectional view taken along E-E in FIG. 2A. As shown in FIGS. 2A to 2C, for example, the substrate **10** includes a base **12**, a side wall **14** that protrudes from the base **12**, and a recess **10a** formed by the base **12** and the side wall **14**.

[0033] The base **12** has a protrusion **12a** and the protrusion **12a** is formed inside of the recess **10a**. Since the use of the base **12** having the protrusion **12a** described above enables warpage of the base **12** (this warpage is particularly likely to occur when the base **12** and the side wall **14** are made of different materials), which may occur due to the substrate **10** having the recess **10a** to be suppressed, the semiconductor laser elements **30** and the like can be easily mounted to the base **12**. In addition, since arranging members such as the semiconductor laser elements **30** on the protrusion **12a** enables the members to be brought closer to the lens array **20**, diffusion of laser beams on the light incident surfaces LA of the lens array **20** (the lens sections **22**) can also be suppressed. Shapes and thicknesses of the substrate **10**, the base **12**, and the side wall **14** are not particularly limited and, for example, in addition to a member having the recess **10a**, a flat plate-like member (for example, a member without the side wall **14** and solely constituted by the base **12**) can also be used as the substrate **10**.

[0034] For example, a metal material such as iron, iron alloy, and copper, a ceramic material such as AlN, SiC, and SiN, or a material combining these materials can be used as the substrate **10** (the base **12** and the side wall **14**).

[0035] The substrate **10** is provided with wirings **90** (for example, leads) for electrically connecting the light-emitting device **1** to the outside. While the wirings **90** may be provided anywhere on an outer edge of the light-emitting device **1**, the wirings **90** are preferably provided on an upper surface or a side surface of the substrate **10**. In other words, the wirings **90** are preferably not provided on a lower surface of the substrate **10**. Accordingly, since an entire lower surface of the substrate **10** can be used as a mounting surface, even in a case where a plurality of semiconductor laser elements **30** that are heat sources are arranged on one substrate **10** as in the present disclosure, a light-emitting device with satisfactory heat dissipation can be provided. When providing the wirings **90** on the side wall **14** of the substrate **10**, since a height of the side wall **14** must be at a certain height or higher, the semiconductor laser elements **30** and the like arranged on the base **12** are to be arranged further away from the lens array **20** as compared to a case where the wirings **90** are not provided on the side wall **14**. However, even in such a case, the use of the base **12** having the protrusion **12a** described above enables the semiconductor laser elements **30**, a mirror **50**, and

the like to be arranged closer to the lens array **20** (the lens sections **22**).

## Lens Array **20**

[0036] FIG. **3A** is a schematic plan view of a lens array. FIG. **3B** is a sectional view taken along F-F in FIG. **3A**. FIG. **3C** is a sectional view taken along G-G in FIG. **3A**. FIG. **3D** is a sectional view taken along H-H in FIG. **3A**. As shown in FIGS. **3A** to **3D**, the lens array **20** has a plurality of lens sections **22** and a connecting section **24**. Each lens section **22** has a light incident surface LA and a light-emitting surface LB, and each laser beam incident to the light incident surface LA of each lens section **22** is refracted and emitted from the light-emitting surface LB of each lens section **22**. The connecting section **24** connects lens sections **22** adjacent to each other in a column direction (a Y direction in FIG. **3A**). Alternatively, the lens array **20** can be solely constituted by the lens sections **22**. In this case, for example, the lens sections **22** are directly connected to each other without involving the connecting section **24**. The lens array **20** (the lens sections **22** and the connecting section **24**) can be formed using a transmissive material such as glass or synthetic quartz.

## Plurality of Lens Sections **22**

[0037] The plurality of lens sections **22** are provided in an m-row, n-column ( $m \geq 2$ ,  $n \geq 1$ ) matrix pattern. The plurality of lens sections **22** have an inter-vertex distance PX in the row direction (an X direction in FIG. **3A**) that is smaller than both a maximum outer diameter E of each of the lens sections **22** and an inter-vertex distance PY in the column direction (the Y direction in FIG. **3A**). Accordingly, since the respective lens sections **22** are consecutively formed in the row direction (the X direction in FIG. **3A**), a waste in space where a laser beam is not emitted in the row direction (the X direction in FIG. **3A**) can be reduced and downsizing of the lens array **20** (and, by extension, downsizing of the light-emitting device **1**) can be achieved. An “inter-vertex distance in the column direction” refers to an inter-vertex distance between adjacent lens sections in the column direction. In addition, an “inter-vertex distance in the row direction” refers to an inter-vertex distance between adjacent lens sections in the row direction. A “vertex” refers to a center of a lens section in a plan view and a “maximum outer diameter” refers to a maximum diameter among diameters of the lens section in a plan view.

[0038] The inter-vertex distance PY in the column direction (the Y direction in FIG. **3A**) can be set preferably in a range of 1 mm or more and 12 mm or less, and more preferably in a range of 3 mm or more and 9 mm or less. The inter-vertex distance PX in the row direction (the X direction in FIG. **3A**) can be set preferably in a range of 0.5 mm or more and 9 mm or less, and more preferably in a range of 2 mm or more and 6 mm or less. By setting the inter-vertex distance PX and the inter-vertex distance PY to these lower limit values or more, mutual interference between laser beams from adjacent semiconductor laser elements **30** can be suppressed. By setting the inter-vertex distance PX and the inter-vertex distance PY to these upper limit values or less, a smaller light-emitting device can be provided.

[0039] The maximum outer diameter E of each lens sections **22** can be set preferably in a range of 1 time or more and 2 times or less, and more preferably in a range of 1.25 times or more and 1.75 times or less of the inter-vertex distance PX. By setting the maximum outer diameter E to these lower limit values or more, mutual interference between laser beams from adjacent semiconductor laser elements **30** can be suppressed. By setting the maximum outer diameter E to these upper limit values or less, a smaller light-emitting device can be provided.

[0040] Each of the lens sections **22** has a same curvature in the row direction (the X direction in FIG. **3A**) and in the column direction (the Y direction in FIG. **3A**). In other words, each of the lens sections **22** has a curved line with a curvature RX in a cross section in the row direction (the X direction in FIG. **3A**) that passes through the vertex of the lens section **22** and a curved line with a curvature RY that is equal to the curvature RX (curvature RX=curvature RY) in a cross section in the column direction (the Y direction in FIG. **3A**) that passes through the vertex of the lens section **22**. Accordingly, even when the lens array **20** is mounted slightly rotated from a prescribed

direction, a significant deviation is less likely to occur in a positional relationship between a light source (the semiconductor laser element **30** or, when the mirror **50** is provided, the mirror **50**: hereinafter, the same description will apply) and the lens section **22**. Preferably, each of the lens sections **22** has a same curvature not only in the row direction (the X direction in FIG. **3A**) and in the column direction (the Y direction in FIG. **3A**) but in all directions passing through the vertex of each lens section **22**. In other words, each of the lens sections **22** has curved lines with a same curvature in all cross section that pass through the vertex of each lens section **22**. Accordingly, a significant deviation is more unlikely to occur in a positional relationship between the light source and the lens section **22**.

[0041] While not particularly limited, each of the plurality of lens sections **22** preferably has a shape capable of parallelizing (collimating) laser beam incident from each of the semiconductor laser elements **30**. For example, preferably, at least a part of each of the plurality of lens sections **22** has an aspherical curved surface (for example, the light incident surface LA is a flat surface and the light-emitting surface LB is an aspherical curved surface). Accordingly, laser beams from the semiconductor laser elements **30** can be parallelized without changing light intensity distribution.

[0042] Preferably, at least a part of outer edge of each of the plurality of lens sections **22** has an arc shape in a plan view. Accordingly, compared to a case where the outer edge of each of the plurality of lens sections **22** is constituted by other shapes in a plan view, since a larger number of aspherical curved surfaces can be provided in the lens sections **22**, laser beams from the semiconductor laser elements **30** can be emitted from the lens sections **22** in an efficient manner.

[0043] The lens array **20** can be fixed to the substrate **10** (when a sealing member **80** is provided between the substrate **10** and the lens array **20**, the sealing member **80**) by known methods. For example, when directly fixing the lens array **20** to the substrate **10**, the lens array **20** and the substrate **10** can be fixed to each other by methods such as adhesion fixing, laser welding, resistance welding, or the like. When the lens array **20** is fixed by laser welding, resistance welding or the like, at least a part of the lens array **20** to be subjected to a welding process is constituted by a metal material. When the sealing member **80** is provided between the substrate **10** and the lens array **20**, the lens array **20** and the sealing member **80** can be adhesively fixed to each other using an adhesive such as a UV curable adhesive.

[0044] In order to make a space in which the semiconductor laser elements **30** are arranged a sealed space, preferably, the substrate **10** and a member that covers the substrate **10** are fixed by welding. However, welding is likely to cause displacement. Therefore, when the lens array is directly fixed to the substrate by welding and the substrate is directly covered by the lens array, there is a risk that the lens array may become displaced and incapable of causing incidence of light from the semiconductor laser elements in a prescribed mode (for example, a prescribed beam divergence angle or a prescribed positional relationship). In consideration thereof, in the present embodiment, the sealing member **80** that is a separate member from the lens array **20** is provided and the substrate **10** is to be covered by the sealing member **80**. Accordingly, the lens array **20** can be fixed to the sealing member **80** by a UV curable adhesive while fixing the sealing member **80** to the substrate **10** by welding. Thus, displacement of the lens array **20** can be suppressed while making a sealed space where the semiconductor laser elements **30** are arranged by the sealing member **80**.

#### Plurality of Semiconductor Laser Elements **30**

[0045] FIG. **4A** is a schematic plan view of semiconductor laser elements arranged on the substrate. FIG. **4B** is a sectional view taken along I-I in FIG. **4A**. FIG. **4C** is a sectional view taken along J-J in FIG. **4A**. FIG. **4D** is a diagram showing an enlargement of a portion enclosed by a dashed line in FIG. **4C**. As shown in FIGS. **4A** to **4D**, the plurality of semiconductor laser elements **30** are arranged on the substrate **10**. Specifically, the plurality of semiconductor laser elements **30** are arranged in the row direction (the X direction in FIG. **4A**) and in the column direction (the Y direction in FIG. **4A**). For example, each of the semiconductor laser elements **30** can be directly arranged on a bottom surface of the recess **10a** (when using the base **12** having the protrusion **12a**,

on the protrusion **12a**) of the substrate **10** or can be arranged via a mounting body **40** or the like. By arranging each of the semiconductor laser elements **30** via the mounting body **40**, heat generated by each of the semiconductor laser elements **30** can be efficiently dissipated via the mounting body **40**. [0046] The plurality of semiconductor laser elements **30** emit respective laser beams, and each laser beam is incident to the light incident surface LA of each lens section **22** either directly or reflected by the mirror **50** or the like. Each laser beam has a beam shape with a greater width in the column direction (the Y direction in FIG. 4A) than in the row direction (the X direction in FIG. 4A) on the light incident surface LA of each of the plurality of lens sections **22** (beam width in the column direction WY>beam width in the row direction WX). Semiconductor laser element using nitride semiconductor or the like can be used as the semiconductor laser element **30**.

[0047] The plurality of semiconductor laser elements **30** can be electrically connected to each other by wires **60** or the like. As the wires **60**, gold, silver, copper, aluminum, or the like can be used. While a mode of connection is not particularly limited, for example, the plurality of semiconductor laser elements **30** provided in the row direction (the X direction in FIG. 4A) can be serially connected to one another using the wires **60**.

[0048] In FIG. 4A, the plurality of semiconductor laser elements **30** are arranged on a straight line in each row and a relay member **70** is provided between adjacent semiconductor laser elements **30**. In addition, adjacent semiconductor laser elements **30** are electrically connected to each other by the wires **60** via the relay member **70**. Accordingly, since a length of each wire **60** can be relatively shortened, an increase in electric resistance can be suppressed. Furthermore, since a distance between adjacent semiconductor laser elements **30** can be made long in each row, thermal interference between adjacent semiconductor laser elements **30** can be reduced. As the relay member **70**, a metal material such as iron, iron alloy, or copper or an insulating material such as AlN, SiC, or SiN having electric wiring formed on an upper surface thereof can be used. The semiconductor laser element **30** is not arranged on the relay member **70**.

[0049] Preferably, an upper surface of the relay member **70** is positioned at a substantially same height as an upper surface of the mounting body **40** or an upper surface of the semiconductor laser element **30**. Accordingly, the wires **60** can be mounted more easily. When the semiconductor laser element **30** is provided on the mounting body **40**, the upper surface of the relay member **70** is positioned at a substantially same height as the upper surface of the mounting body **40**.

Accordingly, compared to a case where the upper surface of the relay member **70** is positioned at a substantially same height as the upper surfaces of the semiconductor laser elements **30**, a thickness of the relay member **70** in a height direction can be made small and member cost can be reduced.

[0050] Each of the semiconductor laser elements **30** is arranged in m-row×n-column ( $m \geq 2$ ,  $n \geq 1$ ) in correspondence with each lens section. In this case, preferably, the number of the semiconductor laser elements **30** in the row direction is larger than the number of the semiconductor laser elements **30** in the column direction. In addition each of the semiconductor laser elements **30** is preferably disposed such that a distribution of light from the plurality of semiconductor laser elements **30** (light as the light-emitting device **1**) forms a square. Accordingly, when the light-emitting device **1** is used as a part of a projector, a distribution of light intensity can be more easily made uniform.

#### Mirror **50**

[0051] As shown in FIGS. 4A to 4D, the light-emitting device **1** may include, on the substrate **10**, a mirror **50** that reflects emission light of the semiconductor laser element **30** toward the lens section **22**. The mirror **50** is arranged so that a light-emitting surface (a surface that emits a laser beam: hereinafter, the same description will apply) of the semiconductor laser element **30** and the mirror **50** are opposed to each other. Accordingly, a travel distance of a laser beam from the light-emitting surface of the semiconductor laser element **30** to the light-emitting surface of the lens section **22** (hereinafter, referred to as an “optical path length”) can be increased. Thus, optical density on the light-emitting surface of the lens array **20** can be reduced and optical dust collection on the surface of the lens sections **22** can be suppressed more easily. In addition, by increasing the optical path

length, a change in an intensity distribution of light emitted from the lens sections **22** can be reduced as compared to cases where the optical path length is shorter (for example, a case where the mirror is not arranged and light is directly irradiated from the semiconductor laser element to the lens section). This is because, by increasing the optical path length, even if light from the semiconductor laser elements **30** is incident to the light incident surfaces of the lens sections **22** in a direction other than perpendicular due to a displacement of the semiconductor laser elements **30**, an inclination of the light after passing the lens sections **22** can be reduced.

[0052] The number, a shape, and the like of the mirror **50** are not particularly limited. For example, a plurality of mirrors that are elongated in the row direction (the X direction in FIG. **4A**) may be arranged in a plurality in the column direction or a plurality of mirrors **50** may be arranged in a pattern of a matrix of m-rows×n-columns ( $m \geq 2$ ,  $n \geq 1$ ) in correspondence with the plurality of lens sections **22**. When arranging the mirrors **50** in a matrix pattern, since one mirror **50** is provided corresponding to each of the plurality of lens sections **22**, even if a deviation occurs in a positional relationship between a given semiconductor laser element **30** and a given mirror **50**, positional relationships between the other semiconductor laser elements **30** and the other mirrors **50** are not affected by the deviation. Therefore, an influence due to deviation in mounting of one mirror **50** can be minimized.

[0053] Glass, synthetic quartz, sapphire, aluminum, or the like can be used for the mirror **50**. The mirror **50** has a reflecting surface that reflects emission light of the semiconductor laser element **30** (a laser beam emitted from the semiconductor laser elements **30**: hereinafter, the same description will apply). For example, a reflective film such as a dielectric multilayer film is provided on the reflecting surface. When causing each emission light of the plurality of semiconductor laser elements **30** to be incident as-is to the lens array **20** without using the mirror **50**, for example, the plurality of semiconductor laser elements **30** are arranged instead of mirrors **50** on the substrate **10** in a pattern of a matrix of m-row×n-columns ( $m \geq 2$ ,  $n \geq 1$ ).

[0054] Although not particularly limited, preferably, the mirror **50** is positioned directly below the vertex of the lens section **22**. Particularly preferably, a reflecting part of the mirror **50** is positioned directly below the vertex of the lens section **22**. Accordingly, since emission light of the semiconductor laser element **30** can be reflected by the mirror **50** toward the vertex of the lens section **22**, an intensity distribution of light emitted from the lens array **20** (the lens sections **22**) is less susceptible to change. In this case, a reflecting part refers to a portion that reflects emission light of the semiconductor laser element **30** in the reflecting surface of the mirror **50**.

[0055] As shown in FIGS. **1A** to **1D** (for example, refer to the semiconductor laser element **30** and the mirror **50** transparently shown in the lens section **22** at a top left position in FIG. **1A**), preferably, the semiconductor laser element **30** and the mirror **50** are arranged on an inner side of outer edge of the lens section **22** in a plan view. Accordingly, since the semiconductor laser element **30** is arranged near the mirror **50**, an increase in an area of light emitted from the lens section **22** can be suppressed.

#### Sealing Member **80**

[0056] As shown in FIGS. **1A** to **1D**, the light-emitting device **1** may include a sealing member **80** between the substrate **10** and the lens array **20**. Providing the sealing member **80** enables a hermetic sealing effect to be increased as compared to a case where only the lens array **20** is provided. In particular, when using nitride semiconductor as the semiconductor laser element **30**, since organic material or the like is likely to collect on the emitting surface of the semiconductor laser element **30**, a hermetic sealing effect by the sealing member **80** becomes more prominent.

[0057] FIG. **5A** is a schematic plan view of the sealing member. In addition, FIG. **5B** is a sectional view taken along K-K in FIG. **5A** and FIG. **5C** is a sectional view taken along L-L in FIG. **5A**. In FIG. **5A**, window parts **82a** are transparently shown using dashed lines in order to facilitate understanding. As shown in FIGS. **5A** to **5C**, the sealing member **80** includes a body part **82** having a plurality of window parts **82a** and a transmissive member **84**. As the body part **82**, glass, metal,

ceramics, or a material combining these materials can be used and, metal can be preferably used. Accordingly, since the substrate **10** and the sealing member **80** can be fixed to each other by welding or the like, hermetic sealing can be more easily achieved. Furthermore, as the transmissive member **84**, a member that allows transmission of at least emission light of the semiconductor laser elements **30** can be used. Shapes of the body part **82** and the transmissive member **84** are not particularly limited. For example, while the body part **82** includes a recess **82b** on a side of the lens array **20** in the present embodiment, when using a flat plate-shape member as the substrate **10**, the recess **82b** may be provided on the side of the substrate **10**.

[0058] While the body part **82** may include one window section **82a** corresponding to two or more semiconductor laser elements **30**, preferably, the body part **82** respectively includes one window section **82a** corresponding to one semiconductor laser element **30**. Accordingly, since a bonding area between the body part **82** and the transmissive member **84** excluding the window parts **82a** can be increased, cracking of the transmissive member **84** due to stress can be suppressed when bonding the substrate **10** and the body part **82** to each other by resistance welding or the like to achieve a hermetic seal.

[0059] As described above, with the light-emitting device **1** according to the first embodiment, the plurality of lens sections **22** have a same curvature in the row direction (the X direction in FIG. **1A**) and in the column direction (the Y direction in FIG. **1A**). Therefore, a light-emitting device can be provided in which, even when the lens array **20** is mounted slightly rotated from a prescribed direction, a significant deviation is less likely to occur in a positional relationship between a light source and the lens section **22** and intensity distribution of light emitted from the lens array **20** is less susceptible to change.

#### Light-Emitting Device 2 According to Second Embodiment

[0060] FIG. **6A** is a schematic plan view of a light-emitting device according to the second embodiment, FIG. **6B** is a sectional view taken along M-M in FIG. **6A**, FIG. **6C** is a sectional view taken along N-N in FIG. **6A**, and FIG. **6D** is a sectional view taken along O-O in FIG. **6A**. In FIG. **6A**, the semiconductor laser element **30** and the like that are arranged below a top left lens section are transparently shown in order to facilitate understanding. As shown in FIGS. **6A** to **6D**, a light-emitting device **2** according to the second embodiment differs from the light-emitting device **1** according to the first embodiment in that a plurality of lens arrays **20A**, **20B**, **20C**, and **20D** are arranged in the column direction (the Y direction in FIG. **6A**), and each of the plurality of lens arrays **20A**, **20B**, **20C**, and **20D** have a plurality of lens sections **22** in the row direction (the X direction in FIG. **6A**). With the second embodiment, in a similar manner to the first embodiment, a light-emitting device can be provided in which, even when the lens array **20** is mounted slightly rotated from a prescribed direction, a significant deviation is less likely to occur in a positional relationship between a light source and the lens section **22** and intensity distribution of light emitted from the lens array **20** is less susceptible to change.

#### Light-Emitting Device 3 According to Third Embodiment

[0061] FIG. **7** is a schematic plan view of a light-emitting device **3** according to the third embodiment. In FIG. **7**, an outer edge of the recess **82b** is indicated by a dashed line. In addition, in FIG. **7**, hatchings are applied to a region in which the lens array **20** is fixed to the sealing member **80** by an adhesive. As shown in FIG. **7**, in the light-emitting device **3**, the lens array **20** includes a connecting part **24** that connects lens sections **22** with each other and is fixed to the sealing member **80** at the connecting part **24** by the adhesive. The sealing member **80** includes the recess **82b**, which is recessed toward a region where a plurality of semiconductor laser elements **30** are mounted on the substrate **10**. In a plan view, the lens array **20** includes a through-hole **F** at an inner side of the recess **82b** and is fixed to the sealing member **80** by the adhesive at an outer side of the recess **82b**.

[0062] When a space between the lens array and the sealing member is a sealed space, in a case where the lens array is fixed by an adhesive (for example, a UV curable adhesive) containing

organic material, gas vaporized from the adhesive pools in the space between the lens array and the sealing member. In this case, the organic material contained in the vaporized gas may react to laser beam and may collect on the transmissive member or the lower surface of the lens array. In contrast, since the space between the lens array **20** and the sealing member **80** becomes an open space by providing the through-hole **F** in the connecting part **24**, gas vaporized from the adhesive is released to the outside of the space and collection of organic material (optical dust collection) can be more easily suppressed. The open space refers to a space that is open to an area outside the light-emitting device.

[0063] Preferably, a plurality of through-holes **F** are provided. In addition the plurality of through-holes **F** are preferably provided so as to be symmetrical with respect to a center line of the lens array **20**. Accordingly, since a flow of air can be more easily formed in the space between the lens array **20** and the sealing member **80** (for example, when two through-holes are line-symmetrically provided, an air flow involving air flowing into the space via one of the through-holes and air flowing out from the space via the other through-hole is more easily formed), gas vaporized from the adhesive is further released to the outside of the space and collection of organic material (optical dust collection) in the space can be further easily suppressed. In addition, an occurrence of dew condensation in the space between the lens array **20** and the sealing member **80** can also be suppressed. Since an adhesive containing organic material such as a UV curable adhesive is a material that tends to absorb moisture, when the lens array **20** is fixed by a UV curable adhesive, moisture absorbed by the adhesive from the atmosphere is likely to pool in the space between the sealing member **80** and the lens array **20** and, depending on usage, dew condensation may occur in the space. Therefore, the configuration described above in which a flow of air is formed in the space can be particularly preferably applied to a case where the lens array **20** is fixed to the sealing member **80** by an adhesive containing organic material such as a UV curable adhesive.

Light-Emitting Device **4** According to Fourth Embodiment

[0064] FIG. **8** is a schematic plan view of a light-emitting device **4** according to a fourth embodiment. In FIG. **8**, an outer edge of the recess **82b** is indicated by a solid line and a dashed line. In addition, in FIG. **8**, hatchings are applied to a region in which the lens array **20** is fixed to the sealing member **80** by an adhesive. As shown in FIG. **8**, in the light-emitting device **4**, the sealing member **80** includes the recess **82b**, which is recessed toward a region where a plurality of semiconductor laser elements **30** are mounted on the substrate **10**. In a plan view, a part of an outer edge of the lens array **20** is arranged so as to be positioned at an inner side of the recess **82b** (refer to an opening **G** in FIG. **8**) and the lens array **20** is fixed to the sealing member **80** by an adhesive at an outer side of the recess **82b**. Even with the light-emitting device **4**, since the space between the lens array **20** and the sealing member **80** becomes an open space, collection of organic material (optical dust collection) and an occurrence of dew condensation can be more easily suppressed.

[0065] The number and an arrangement of the opening **G** need only enable a part of the outer edge of the lens array **20** to be positioned at the inner side of the recess **82b** and are not limited to the number and the arrangement illustrated in FIG. **8**. However, preferably, the opening **G** is provided at two or more locations (not limited to four corners) at the outer edge of the lens array **20**. In addition, in this case, preferably, the openings **G** are provided so as to be symmetrical with respect to a center of the lens array **20**. Accordingly, in a similar manner to a case where a plurality of through-holes **F** are provided so as to be symmetrical with respect to the center line of the lens array **20**, a flow of air is more likely to be formed in the space between the lens array **20** and the sealing member **80**. Therefore, collection of organic material (optical dust collection) and an occurrence of dew condensation can be even more easily suppressed.

[0066] While the third and fourth embodiments have been described above, the through-hole **F** and the opening **G** are examples of specific configurations for making the space between the lens array **20** and the sealing member **80** an open space. The space between the lens array **20** and the sealing member **80** need only be opened so that gas generated inside the space can be released to the

outside and a specific configuration of such an open state is not particularly limited.  
[0067] While embodiments have been described above, the description is not intended to limit in any way the invention described in the claims.

## Claims

1. A light-emitting device comprising: a base having an upper surface; one or more semiconductor laser elements disposed on the upper surface and configured to emit light in a first direction in a top view; one or more reflecting members spaced from the one or more semiconductor laser elements in the first direction in a top view; and a lens member having one or more lens sections through which light reflected by the one or more reflecting members passes, the lens member being fixed to the base and positioned above the one or more semiconductor laser elements and the one or more reflecting members; wherein: in a top view, at least a portion of a first of the one or more reflecting members and an emitting surface of a first of the one or more semiconductor laser elements is disposed in a region inward of an outer edge of a first of the one or more lens sections.
2. The light-emitting device according to claim 1, wherein: the one or more semiconductor laser elements comprise a plurality of semiconductor laser elements disposed on the upper surface of the base in a second direction perpendicular to the first direction in a top view; the one or more lens sections comprise a plurality of lens sections arranged in the second direction; and in a top view, an emitting surface of each of the semiconductor laser elements is disposed in a region inward of an outer edge of a respective one of the plurality of lens sections.
3. The light-emitting device according to claim 2, wherein: the plurality of lens sections are arranged such that an inter-vertex distance between adjacent lens sections in the second direction is smaller than a maximum outer diameter of each of the lens sections.
4. The light-emitting device according to claim 1, wherein: in a top view, the emitting surface of the first semiconductor laser element disposed in the region inward of the outer edge of the first lens member is positioned between (i) a first virtual line that extends parallel to the second direction and passes through one end of a width of light from the first semiconductor laser element in the first direction at a light incident surface of the lens member and (ii) a second virtual line extends parallel to the second direction and passes through another end of the width of light from the first semiconductor laser element in the first direction at the light incident surface of the lens member.
5. The light-emitting device according to claim 4, wherein: in a top view, the width of light from the first semiconductor laser element in the first direction at the light incident surface of the lens member is less than a width of the first lens section in the first direction; and in a top view, a width of light from the semiconductor laser element in the second direction at the light incident surface of the lens member is less than a width of the lens section in the second direction.
6. The light-emitting device according to claim 1, wherein: in a top view, a width in the first direction of the first reflecting member is less than a width in the first direction of the first lens section; and in a top view, a width in the first direction of the first semiconductor laser element is less than the width in the first direction of the first lens section.
7. The light-emitting device according to claim 2, wherein: the one or more reflecting members comprises a plurality of reflecting members arranged on the upper surface of the base in the second direction in a top view; and a distance between adjacent semiconductor laser elements is larger than a distance between adjacent reflecting members.
8. The light-emitting device according to claim 1, further comprising: a plurality of wirings electrically connected to the one or more semiconductor elements; wherein: the plurality of wirings includes a first wiring joined to the first semiconductor laser element; and in a top view, a first portion of the first wiring is disposed within the region inward of the outer edge of the first lens section and a second portion of the first wiring is located outward of the outer edge of the first lens

section.

**9.** The light-emitting device according to claim 1, further comprising: one or more mounting bodies on which the one or more semiconductor elements are disposed.

**10.** The light-emitting device according to claim 2, wherein: the one or more lens sections comprise five or more lens sections arranged in the second direction.

**11.** The light-emitting device according to claim 1, further comprising: a sealing member being fixed to the base; wherein: the lens member is fixed to the base via the sealing member; the one or more semiconductor laser elements are disposed in a sealed space; and the lens member is located outside the sealed space.
