ABSTRACT

Disclosed herein are systems and methods for storing, organizing, and maintaining acoustic data for mixed reality systems. A system may include one or more sensors of a head-wearable device, a speaker of the head-wearable device, and one or more processors. A method performed by the one or more processors may include receiving a request to present an audio signal. An environment may be identified via the one or more sensors of the head-wearable device. One or more audio model components associated with the environment may be retrieved. A first audio model may be generated based on the audio model components. A second audio model may be generated based on the first audio model. A modified audio signal may be determined based on the second audio model and based on the request to present an audio signal. The modified audio signal may be presented via the speaker of the head-wearable device.

[0001] This application is a Continuation of U.S. Non-Provisional application Ser. No. 18/180,746, filed Mar. 8, 2023, which is a Continuation of U.S. Non-Provisional application Ser. No. 17/112,969, filed Dec. 4, 2020, now U.S. Pat. No. 11,627,430, which claims the benefit of U.S. Provisional Application No. 62/944,956, filed on Dec. 6, 2019, the entire disclosure of which is incorporated herein by reference for all purposes.

FIELD

[0002] This disclosure relates in general to systems and methods for managing and storing audio data, and in particular to systems and methods for managing and storing audio data in a mixed reality environment.

BACKGROUND

[0003] Virtual environments are ubiquitous in computing environments, finding use in video games (in which a virtual environment may represent a game world); maps (in which a virtual environment may represent terrain to be navigated); simulations (in which a virtual environment may simulate a real environment); digital storytelling (in which virtual characters may interact with each other in a virtual environment); and many other applications. Modern computer users are generally comfortable perceiving, and interacting with, virtual environments. However, users' experiences with virtual environments can be limited by the technology for presenting virtual environments. For example, conventional displays (e.g., 2D display screens) and audio systems (e.g., fixed speakers) may be unable to realize a virtual environment in ways that create a compelling, realistic, and immersive experience.

[0004] Virtual reality ("VR"), augmented reality ("AR"), mixed reality ("MR"), and related technologies (collectively, "XR") share an ability to present, to a user of an XR system, sensory information corresponding to a virtual environment represented by data in a computer system. Such systems can offer a uniquely heightened sense of immersion and realism by combining virtual visual and audio cues with real sights and sounds. Accordingly, it can be desirable to present digital sounds to a user of an XR system in such a way that the sounds seem to be occurring—naturally, and consistently with the user's expectations of the sound—in the user's real environment. Generally speaking, users expect that virtual sounds will take on the acoustic properties of the real environment in which they are heard. For instance, a user of an XR system in a large concert hall will expect the virtual sounds of the XR system to have large, cavernous sonic qualities; conversely, a user in a small apartment will expect the sounds to be more dampened, close, and immediate. In addition to matching virtual sounds with acoustic properties of a real and/or virtual environment, realism is further enhanced by spatializing virtual sounds. For example, a virtual object may visually fly past a user from behind, and the user may expect the corresponding virtual sound to similarly reflect the spatial movement of the virtual object with respect to the user.

[0005] Existing technologies often fall short of these expectations, such as by presenting virtual audio that does

not take into account a user's surroundings or does not correspond to spatial movements of a virtual object, leading to feelings of inauthenticity that can compromise the user experience. Observations of users of XR systems indicate that while users may be relatively forgiving of visual mismatches between virtual content and a real environment (e.g., inconsistencies in lighting); users may be more sensitive to auditory mismatches. Our own auditory experiences, refined continuously throughout our lives, can make us acutely aware of how our physical environments affect the sounds we hear; and we can be hyper-aware of sounds that are inconsistent with those expectations. With XR systems, such inconsistencies can be jarring, and can turn an immersive and compelling experience into a gimmicky, imitative one. In extreme examples, auditory inconsistencies can cause motion sickness and other ill effects as the inner ear is unable to reconcile auditory stimuli with their corresponding visual cues.

[0006] A system architecture is needed to organize and manage a system for generating virtual audio. Generating virtual audio may involve managing and storing information about a user's environment so that the information may be used to produce realistic virtual sound. An audio system architecture may therefore need to interface with other systems to receive and utilize information relevant to an audio engine. It can further be desirable to have an audio system architecture that can present realistic sounds without interruption during use. An audio system architecture that can update an audio engine without interrupting a user can produce an immersive user experience where auditory signals continuously reflect a user's environment.

[0007] By taking into account the characteristics of the user's physical environment, the systems and methods described herein can simulate what would be heard by a user if the virtual sound were a real sound, generated naturally in that environment. By presenting virtual sounds in a manner that is faithful to the way sounds behave in the real world, the user may experience a heightened sense of connectedness to the mixed reality environment. Similarly, by presenting location-aware virtual content that responds to the user's movements and environment, the content becomes more subjective, interactive, and real—for example, the user's experience at Point A can be entirely different from his or her experience at Point B. This enhanced realism and interactivity can provide a foundation for new applications of mixed reality, such as those that use spatially-aware audio to enable novel forms of gameplay, social features, or interactive behaviors.

BRIEF SUMMARY

[0008] Disclosed herein are systems and methods for storing, organizing, and maintaining acoustic data for mixed reality systems. A system may include one or more sensors of a head-wearable device, a speaker of the head-wearable device, and one or more processors configured to execute a method. The method for execution by the one or more processors may include receiving a request to present an audio signal. An environment may be identified via the one or more sensors of the head-wearable device. One or more audio model components associated with the environment may be retrieved. A first audio model may be generated based on the audio model components. A second audio model may be generated based on the first audio model. A modified audio signal may be determined based on the

second audio model and based on the request to present an audio signal. The modified audio signal may be presented via the speaker of the head-wearable device.

[0009] In some system embodiments, the second audio model may be generated by an audio service. In some system embodiments, the modified audio signal may be determined by an audio service. In some system embodiments, the second audio model may be a duplicate of the first audio model.

[0010] In some system embodiments, the one or more audio model components may include one or more dimensions of the environment. In some system embodiments, the one or more audio model components may include a reverberation time. In some system embodiments, the one or more audio model components may include a reverberation gain. In some system embodiments, the one or more audio model components may include a transmission loss coefficient. In some system embodiments, the one or more audio model components may include an absorption coefficient.

[0011] A method may include receiving a request to present an audio signal. An environment may be identified via one or more sensors of a head-wearable device. One or more audio model components associated with the environment may be retrieved. A first audio model based on the audio model components may be generated. A second audio model may be generated based on the first audio model. A modified audio signal may be determined based on the second audio model and based on the request to present an audio signal. The modified audio signal may be presented via a speaker of the head-wearable device.

[0012] In some method embodiments, the second audio model may be generated by an audio service. In some method embodiments, the modified audio signal may be determined by an audio service. In some method embodiments, the second audio model may be a duplicate of the first audio model.

[0013] In some method embodiments, the one or more audio model components may include one or more dimensions of the environment. In some method embodiments, the one or more audio model components may include a reverberation time. In some method embodiments, the one or more audio model components may include a reverberation gain. In some method embodiments, the one or more audio model components may include a transmission loss coefficient. In some method embodiments, the one or more audio model components may include an absorption coefficient.

[0014] A non-transitory computer-readable medium may store instructions that, when executed by one or more processors, cause the one or more processors to execute a method. The method for execution by the one or more processors may include: receiving a request to present an audio signal; identifying, via one or more sensors of a head-wearable device, an environment; retrieving one or more audio model components associated with the environment; generating a first audio model based on the audio model components; generating a second audio model based on the first audio model; determining a modified audio signal based on the second audio model and based on the request to present an audio signal; and presenting, via a speaker of the head-wearable device, the modified audio signal.

[0015] In some non-transitory computer-readable medium embodiments, the second audio model may be generated by an audio service. In some non-transitory computer-readable

medium embodiments, the modified audio signal may be determined by an audio service. In some non-transitory computer-readable medium embodiments, the second audio model may be a duplicate of the first audio model.

[0016] In some non-transitory computer-readable medium embodiments, the one or more audio model components may include one or more dimensions of the environment. In some non-transitory computer-readable medium embodiments, the one or more audio model components may include a reverberation time. In some non-transitory computer-readable medium embodiments, the one or more audio model components may include a reverberation gain. In some non-transitory computer-readable medium embodiments, the one or more audio model components may include a transmission loss coefficient. In some non-transitory computer-readable medium embodiments, the one or more audio model components may include an absorption coefficient.

BRIEF DESCRIPTION OF THE DRAWINGS

[0017] FIGS. 1A-1C illustrate an example mixed reality environment, according to some embodiments.

[0018] FIGS. 2A-2D illustrate components of an example mixed reality system that can be used to generate and interact with a mixed reality environment, according to some embodiments.

[0019] FIG. 3A illustrates an example mixed reality hand-held controller that can be used to provide input to a mixed reality environment, according to some embodiments.

[0020] FIG. 3B illustrates an example auxiliary unit that can be used with an example mixed reality system, according to some embodiments.

[0021] FIG. 4 illustrates an example functional block diagram for an example mixed reality system, according to some embodiments.

[0022] FIG. 5 illustrates an example of a virtual audio system, according to some embodiments.

[0023] FIG. 6 illustrates an example process for updating an audio model, according to some embodiments.

[0024] FIG. 7 illustrates an example process for updating an audio model, according to some embodiments.

DETAILED DESCRIPTION

[0025] In the following description of examples, reference is made to the accompanying drawings which form a part hereof, and in which it is shown by way of illustration specific examples that can be practiced. It is to be understood that other examples can be used and structural changes can be made without departing from the scope of the disclosed examples.

Mixed Reality Environment

[0026] Like all people, a user of a mixed reality system exists in a real environment—that is, a three-dimensional portion of the “real world,” and all of its contents, that are perceptible by the user. For example, a user perceives a real environment using one’s ordinary human senses—sight, sound, touch, taste, smell—and interacts with the real environment by moving one’s own body in the real environment. Locations in a real environment can be described as coordinates in a coordinate space; for example, a coordinate can include latitude, longitude, and elevation with respect to sea level; distances in three orthogonal dimensions from a

reference point; or other suitable values. Likewise, a vector can describe a quantity having a direction and a magnitude in the coordinate space.

[0027] A computing device can maintain, for example in a memory associated with the device, a representation of a virtual environment. As used herein, a virtual environment is a computational representation of a three-dimensional space. A virtual environment can include representations of any object, action, signal, parameter, coordinate, vector, or other characteristic associated with that space. In some examples, circuitry (e.g., a processor) of a computing device can maintain and update a state of a virtual environment; that is, a processor can determine at a first time t_0 , based on data associated with the virtual environment and/or input provided by a user, a state of the virtual environment at a second time t_1 . For instance, if an object in the virtual environment is located at a first coordinate at time t_0 , and has certain programmed physical parameters (e.g., mass, coefficient of friction); and an input received from user indicates that a force should be applied to the object in a direction vector; the processor can apply laws of kinematics to determine a location of the object at time t_1 using basic mechanics. The processor can use any suitable information known about the virtual environment, and/or any suitable input, to determine a state of the virtual environment at a time t_1 . In maintaining and updating a state of a virtual environment, the processor can execute any suitable software, including software relating to the creation and deletion of virtual objects in the virtual environment; software (e.g., scripts) for defining behavior of virtual objects or characters in the virtual environment; software for defining the behavior of signals (e.g., audio signals) in the virtual environment; software for creating and updating parameters associated with the virtual environment; software for generating audio signals in the virtual environment; software for handling input and output; software for implementing network operations; software for applying asset data (e.g., animation data to move a virtual object over time); or many other possibilities.

[0028] Output devices, such as a display or a speaker, can present any or all aspects of a virtual environment to a user. For example, a virtual environment may include virtual objects (which may include representations of inanimate objects; people; animals; lights; etc.) that may be presented to a user. A processor can determine a view of the virtual environment (for example, corresponding to a “camera” with an origin coordinate, a view axis, and a frustum); and render, to a display, a viewable scene of the virtual environment corresponding to that view. Any suitable rendering technology may be used for this purpose. In some examples, the viewable scene may include only some virtual objects in the virtual environment, and exclude certain other virtual objects. Similarly, a virtual environment may include audio aspects that may be presented to a user as one or more audio signals. For instance, a virtual object in the virtual environment may generate a sound originating from a location coordinate of the object (e.g., a virtual character may speak or cause a sound effect); or the virtual environment may be associated with musical cues or ambient sounds that may or may not be associated with a particular location. A processor can determine an audio signal corresponding to a “listener” coordinate—for instance, an audio signal corresponding to a composite of sounds in the virtual environment, and mixed and processed to simulate an audio signal that would be

heard by a listener at the listener coordinate—and present the audio signal to a user via one or more speakers.

[0029] Because a virtual environment exists only as a computational structure, a user cannot directly perceive a virtual environment using one’s ordinary senses. Instead, a user can perceive a virtual environment only indirectly, as presented to the user, for example by a display, speakers, haptic output devices, etc. Similarly, a user cannot directly touch, manipulate, or otherwise interact with a virtual environment; but can provide input data, via input devices or sensors, to a processor that can use the device or sensor data to update the virtual environment. For example, a camera sensor can provide optical data indicating that a user is trying to move an object in a virtual environment, and a processor can use that data to cause the object to respond accordingly in the virtual environment.

[0030] A mixed reality system can present to the user, for example using a transmissive display and/or one or more speakers (which may, for example, be incorporated into a wearable head device), a mixed reality environment (“MRE”) that combines aspects of a real environment and a virtual environment. In some embodiments, the one or more speakers may be external to the head-mounted wearable unit. As used herein, a MRE is a simultaneous representation of a real environment and a corresponding virtual environment. In some examples, the corresponding real and virtual environments share a single coordinate space; in some examples, a real coordinate space and a corresponding virtual coordinate space are related to each other by a transformation matrix (or other suitable representation). Accordingly, a single coordinate (along with, in some examples, a transformation matrix) can define a first location in the real environment, and also a second, corresponding, location in the virtual environment; and vice versa.

[0031] In a MRE, a virtual object (e.g., in a virtual environment associated with the MRE) can correspond to a real object (e.g., in a real environment associated with the MRE). For instance, if the real environment of a MRE includes a real lamp post (a real object) at a location coordinate, the virtual environment of the MRE may include a virtual lamp post (a virtual object) at a corresponding location coordinate. As used herein, the real object in combination with its corresponding virtual object together constitute a “mixed reality object.” It is not necessary for a virtual object to perfectly match or align with a corresponding real object. In some examples, a virtual object can be a simplified version of a corresponding real object. For instance, if a real environment includes a real lamp post, a corresponding virtual object may include a cylinder of roughly the same height and radius as the real lamp post (reflecting that lamp posts may be roughly cylindrical in shape). Simplifying virtual objects in this manner can allow computational efficiencies, and can simplify calculations to be performed on such virtual objects. Further, in some examples of a MRE, not all real objects in a real environment may be associated with a corresponding virtual object. Likewise, in some examples of a MRE, not all virtual objects in a virtual environment may be associated with a corresponding real object. That is, some virtual objects may solely in a virtual environment of a MRE, without any real-world counterpart.

[0032] In some examples, virtual objects may have characteristics that differ, sometimes drastically, from those of corresponding real objects. For instance, while a real envi-

ronment in a MRE may include a green, two-armed cactus—a prickly inanimate object—a corresponding virtual object in the MRE may have the characteristics of a green, two-armed virtual character with human facial features and a surly demeanor. In this example, the virtual object resembles its corresponding real object in certain characteristics (color, number of arms); but differs from the real object in other characteristics (facial features, personality). In this way, virtual objects have the potential to represent real objects in a creative, abstract, exaggerated, or fanciful manner; or to impart behaviors (e.g., human personalities) to otherwise inanimate real objects. In some examples, virtual objects may be purely fanciful creations with no real-world counterpart (e.g., a virtual monster in a virtual environment, perhaps at a location corresponding to an empty space in a real environment).

[0033] Compared to VR systems, which present the user with a virtual environment while obscuring the real environment, a mixed reality system presenting a MRE affords the advantage that the real environment remains perceptible while the virtual environment is presented. Accordingly, the user of the mixed reality system is able to use visual and audio cues associated with the real environment to experience and interact with the corresponding virtual environment. As an example, while a user of VR systems may struggle to perceive or interact with a virtual object displayed in a virtual environment—because, as noted above, a user cannot directly perceive or interact with a virtual environment—a user of a MR system may find it intuitive and natural to interact with a virtual object by seeing, hearing, and touching a corresponding real object in his or her own real environment. This level of interactivity can heighten a user's feelings of immersion, connection, and engagement with a virtual environment. Similarly, by simultaneously presenting a real environment and a virtual environment, mixed reality systems can reduce negative psychological feelings (e.g., cognitive dissonance) and negative physical feelings (e.g., motion sickness) associated with VR systems. Mixed reality systems further offer many possibilities for applications that may augment or alter our experiences of the real world.

[0034] FIG. 1A illustrates an example real environment 100 in which a user 110 uses a mixed reality system 112. Mixed reality system 112 may include a display (e.g., a transmissive display) and one or more speakers, and one or more sensors (e.g., a camera), for example as described below. The real environment 100 shown includes a rectangular room 104A, in which user 110 is standing; and real objects 122A (a lamp), 124A (a table), 126A (a sofa), and 128A (a painting). Room 104A further includes a location coordinate 106, which may be considered an origin of the real environment 100. As shown in FIG. 1A, an environment/world coordinate system 108 (comprising an x-axis 108X, a y-axis 108Y, and a z-axis 108Z) with its origin at point 106 (a world coordinate), can define a coordinate space for real environment 100. In some embodiments, the origin point 106 of the environment/world coordinate system 108 may correspond to where the mixed reality system 112 was powered on. In some embodiments, the origin point 106 of the environment/world coordinate system 108 may be reset during operation. In some examples, user 110 may be considered a real object in real environment 100; similarly, user 110's body parts (e.g., hands, feet) may be considered real objects in real environment 100. In some examples, a

user/listener/head coordinate system 114 (comprising an x-axis 114X, a y-axis 114Y, and a z-axis 114Z) with its origin at point 115 (e.g., user/listener/head coordinate) can define a coordinate space for the user/listener/head on which the mixed reality system 112 is located. The origin point 115 of the user/listener/head coordinate system 114 may be defined relative to one or more components of the mixed reality system 112. For example, the origin point 115 of the user/listener/head coordinate system 114 may be defined relative to the display of the mixed reality system 112 such as during initial calibration of the mixed reality system 112. A matrix (which may include a translation matrix and a Quaternion matrix or other rotation matrix), or other suitable representation can characterize a transformation between the user/listener/head coordinate system 114 space and the environment/world coordinate system 108 space. In some embodiments, a left ear coordinate 116 and a right ear coordinate 117 may be defined relative to the origin point 115 of the user/listener/head coordinate system 114. A matrix (which may include a translation matrix and a Quaternion matrix or other rotation matrix), or other suitable representation can characterize a transformation between the left ear coordinate 116 and the right ear coordinate 117, and user/listener/head coordinate system 114 space. The user/listener/head coordinate system 114 can simplify the representation of locations relative to the user's head, or to a head-mounted device, for example, relative to the environment/world coordinate system 108. Using Simultaneous Localization and Mapping (SLAM), visual odometry, or other techniques, a transformation between user coordinate system 114 and environment coordinate system 108 can be determined and updated in real-time.

[0035] FIG. 1B illustrates an example virtual environment 130 that corresponds to real environment 100. The virtual environment 130 shown includes a virtual rectangular room 104B corresponding to real rectangular room 104A; a virtual object 122B corresponding to real object 122A; a virtual object 124B corresponding to real object 124A; and a virtual object 126B corresponding to real object 126A. Metadata associated with the virtual objects 122B, 124B, 126B can include information derived from the corresponding real objects 122A, 124A, 126A. Virtual environment 130 additionally includes a virtual monster 132, which does not correspond to any real object in real environment 100. Real object 128A in real environment 100 does not correspond to any virtual object in virtual environment 130. A persistent coordinate system 133 (comprising an x-axis 133X, a y-axis 133Y, and a z-axis 133Z) with its origin at point 134 (persistent coordinate), can define a coordinate space for virtual content. The origin point 134 of the persistent coordinate system 133 may be defined relative/with respect to one or more real objects, such as the real object 126A. A matrix (which may include a translation matrix and a Quaternion matrix or other rotation matrix), or other suitable representation can characterize a transformation between the persistent coordinate system 133 space and the environment/world coordinate system 108 space. In some embodiments, each of the virtual objects 122B, 124B, 126B, and 132 may have their own persistent coordinate point relative to the origin point 134 of the persistent coordinate system 133. In some embodiments, there may be multiple persistent coordinate systems and each of the virtual objects 122B, 124B, 126B, and 132 may have their own persistent coordinate point relative to one or more persistent coordinate systems.

[0036] With respect to FIGS. 1A and 1B, environment/world coordinate system **108** defines a shared coordinate space for both real environment **100** and virtual environment **130**. In the example shown, the coordinate space has its origin at point **106**. Further, the coordinate space is defined by the same three orthogonal axes (**108X**, **108Y**, **108Z**). Accordingly, a first location in real environment **100**, and a second, corresponding location in virtual environment **130**, can be described with respect to the same coordinate space. This simplifies identifying and displaying corresponding locations in real and virtual environments, because the same coordinates can be used to identify both locations. However, in some examples, corresponding real and virtual environments need not use a shared coordinate space. For instance, in some examples (not shown), a matrix (which may include a translation matrix and a Quaternion matrix or other rotation matrix), or other suitable representation can characterize a transformation between a real environment coordinate space and a virtual environment coordinate space.

[0037] FIG. 1C illustrates an example MRE **150** that simultaneously presents aspects of real environment **100** and virtual environment **130** to user **110** via mixed reality system **112**. In the example shown, MRE **150** simultaneously presents user **110** with real objects **122A**, **124A**, **126A**, and **128A** from real environment **100** (e.g., via a transmissive portion of a display of mixed reality system **112**); and virtual objects **122B**, **124B**, **126B**, and **132** from virtual environment **130** (e.g., via an active display portion of the display of mixed reality system **112**). As above, origin point **106** acts as an origin for a coordinate space corresponding to MRE **150**, and coordinate system **108** defines an x-axis, y-axis, and z-axis for the coordinate space.

[0038] In the example shown, mixed reality objects include corresponding pairs of real objects and virtual objects (i.e., **122A/122B**, **124A/124B**, **126A/126B**) that occupy corresponding locations in coordinate space **108**. In some examples, both the real objects and the virtual objects may be simultaneously visible to user **110**. This may be desirable in, for example, instances where the virtual object presents information designed to augment a view of the corresponding real object (such as in a museum application where a virtual object presents the missing pieces of an ancient damaged sculpture). In some examples, the virtual objects (**122B**, **124B**, and/or **126B**) may be displayed (e.g., via active pixelated occlusion using a pixelated occlusion shutter) so as to occlude the corresponding real objects (**122A**, **124A**, and/or **126A**). This may be desirable in, for example, instances where the virtual object acts as a visual replacement for the corresponding real object (such as in an interactive storytelling application where an inanimate real object becomes a “living” character).

[0039] In some examples, real objects (e.g., **122A**, **124A**, **126A**) may be associated with virtual content or helper data that may not necessarily constitute virtual objects. Virtual content or helper data can facilitate processing or handling of virtual objects in the mixed reality environment. For example, such virtual content could include two-dimensional representations of corresponding real objects; custom asset types associated with corresponding real objects; or statistical data associated with corresponding real objects. This information can enable or facilitate calculations involving a real object without incurring unnecessary computational overhead.

[0040] In some examples, the presentation described above may also incorporate audio aspects. For instance, in MRE **150**, virtual monster **132** could be associated with one or more audio signals, such as a footstep sound effect that is generated as the monster walks around MRE **150**. As described further below, a processor of mixed reality system **112** can compute an audio signal corresponding to a mixed and processed composite of all such sounds in MRE **150**, and present the audio signal to user **110** via one or more speakers included in mixed reality system **112** and/or one or more external speakers.

Example Mixed Reality System

[0041] Example mixed reality system **112** can include a wearable head device (e.g., a wearable augmented reality or mixed reality head device) comprising a display (which may include left and right transmissive displays, which may be near-eye displays, and associated components for coupling light from the displays to the user's eyes); left and right speakers (e.g., positioned adjacent to the user's left and right ears, respectively); an inertial measurement unit (IMU) (e.g., mounted to a temple arm of the head device); an orthogonal coil electromagnetic receiver (e.g., mounted to the left temple piece); left and right cameras (e.g., depth (time-of-flight) cameras) oriented away from the user; and left and right eye cameras oriented toward the user (e.g., for detecting the user's eye movements). However, a mixed reality system **112** can incorporate any suitable display technology, and any suitable sensors (e.g., optical, infrared, acoustic, LIDAR, EOG, GPS, magnetic). In addition, mixed reality system **112** may incorporate networking features (e.g., Wi-Fi capability) to communicate with other devices and systems, including other mixed reality systems. Mixed reality system **112** may further include a battery (which may be mounted in an auxiliary unit, such as a belt pack designed to be worn around a user's waist), a processor, and a memory. The wearable head device of mixed reality system **112** may include tracking components, such as an IMU or other suitable sensors, configured to output a set of coordinates of the wearable head device relative to the user's environment. In some examples, tracking components may provide input to a processor performing a Simultaneous Localization and Mapping (SLAM) and/or visual odometry algorithm. In some examples, mixed reality system **112** may also include a handheld controller **300**, and/or an auxiliary unit **320**, which may be a wearable backpack, as described further below.

[0042] FIGS. 2A-2D illustrate components of an example mixed reality system **200** (which may correspond to mixed reality system **112**) that may be used to present a MRE (which may correspond to MRE **150**), or other virtual environment, to a user. FIG. 2A illustrates a perspective view of a wearable head device **2102** included in example mixed reality system **200**. FIG. 2B illustrates a top view of wearable head device **2102** worn on a user's head **2202**. FIG. 2C illustrates a front view of wearable head device **2102**. FIG. 2D illustrates an edge view of example eyepiece **2110** of wearable head device **2102**. As shown in FIGS. 2A-2C, the example wearable head device **2102** includes an example left eyepiece (e.g., a left transparent waveguide set eyepiece) **2108** and an example right eyepiece (e.g., a right transparent waveguide set eyepiece) **2110**. Each eyepiece **2108** and **2110** can include transmissive elements through which a real environment can be visible, as well as display elements for

presenting a display (e.g., via imagewise modulated light) overlapping the real environment. In some examples, such display elements can include surface diffractive optical elements for controlling the flow of imagewise modulated light. For instance, the left eyepiece **2108** can include a left incoupling grating set **2112**, a left orthogonal pupil expansion (OPE) grating set **2120**, and a left exit (output) pupil expansion (EPE) grating set **2122**. Similarly, the right eyepiece **2110** can include a right incoupling grating set **2118**, a right OPE grating set **2114** and a right EPE grating set **2116**. Imagewise modulated light can be transferred to a user's eye via the incoupling gratings **2112** and **2118**, OPEs **2114** and **2120**, and EPE **2116** and **2122**. Each incoupling grating set **2112**, **2118** can be configured to deflect light toward its corresponding OPE grating set **2120**, **2114**. Each OPE grating set **2120**, **2114** can be designed to incrementally deflect light down toward its associated EPE **2122**, **2116**, thereby horizontally extending an exit pupil being formed. Each EPE **2122**, **2116** can be configured to incrementally redirect at least a portion of light received from its corresponding OPE grating set **2120**, **2114** outward to a user eyepiece position (not shown) defined behind the eyepieces **2108**, **2110**, vertically extending the exit pupil that is formed at the eyepiece. Alternatively, in lieu of the incoupling grating sets **2112** and **2118**, OPE grating sets **2114** and **2120**, and EPE grating sets **2116** and **2122**, the eyepieces **2108** and **2110** can include other arrangements of gratings and/or refractive and reflective features for controlling the coupling of imagewise modulated light to the user's eyes.

[0043] In some examples, wearable head device **2102** can include a left temple arm **2130** and a right temple arm **2132**, where the left temple arm **2130** includes a left speaker **2134** and the right temple arm **2132** includes a right speaker **2136**. An orthogonal coil electromagnetic receiver **2138** can be located in the left temple piece, or in another suitable location in the wearable head unit **2102**. An Inertial Measurement Unit (IMU) **2140** can be located in the right temple arm **2132**, or in another suitable location in the wearable head device **2102**. The wearable head device **2102** can also include a left depth (e.g., time-of-flight) camera **2142** and a right depth camera **2144**. The depth cameras **2142**, **2144** can be suitably oriented in different directions so as to together cover a wider field of view.

[0044] In the example shown in FIGS. 2A-2D, a left source of imagewise modulated light **2124** can be optically coupled into the left eyepiece **2108** through the left incoupling grating set **2112**, and a right source of imagewise modulated light **2126** can be optically coupled into the right eyepiece **2110** through the right incoupling grating set **2118**. Sources of imagewise modulated light **2124**, **2126** can include, for example, optical fiber scanners; projectors including electronic light modulators such as Digital Light Processing (DLP) chips or Liquid Crystal on Silicon (LCoS) modulators; or emissive displays, such as micro Light Emitting Diode (μ LED) or micro Organic Light Emitting Diode (μ OLED) panels coupled into the incoupling grating sets **2112**, **2118** using one or more lenses per side. The input coupling grating sets **2112**, **2118** can deflect light from the sources of imagewise modulated light **2124**, **2126** to angles above the critical angle for Total Internal Reflection (TIR) for the eyepieces **2108**, **2110**. The OPE grating sets **2114**, **2120** incrementally deflect light propagating by TIR down toward the EPE grating sets **2116**, **2122**. The EPE grating

sets **2116**, **2122** incrementally couple light toward the user's face, including the pupils of the user's eyes.

[0045] In some examples, as shown in FIG. 2D, each of the left eyepiece **2108** and the right eyepiece **2110** includes a plurality of waveguides **2402**. For example, each eyepiece **2108**, **2110** can include multiple individual waveguides, each dedicated to a respective color channel (e.g., red, blue and green). In some examples, each eyepiece **2108**, **2110** can include multiple sets of such waveguides, with each set configured to impart different wavefront curvature to emitted light. The wavefront curvature may be convex with respect to the user's eyes, for example to present a virtual object positioned a distance in front of the user (e.g., by a distance corresponding to the reciprocal of wavefront curvature). In some examples, EPE grating sets **2116**, **2122** can include curved grating grooves to effect convex wavefront curvature by altering the Poynting vector of exiting light across each EPE.

[0046] In some examples, to create a perception that displayed content is three-dimensional, stereoscopically-adjusted left and right eye imagery can be presented to the user through the imagewise light modulators **2124**, **2126** and the eyepieces **2108**, **2110**. The perceived realism of a presentation of a three-dimensional virtual object can be enhanced by selecting waveguides (and thus corresponding the wavefront curvatures) such that the virtual object is displayed at a distance approximating a distance indicated by the stereoscopic left and right images. This technique may also reduce motion sickness experienced by some users, which may be caused by differences between the depth perception cues provided by stereoscopic left and right eye imagery, and the autonomic accommodation (e.g., object distance-dependent focus) of the human eye.

[0047] FIG. 2D illustrates an edge-facing view from the top of the right eyepiece **2110** of example wearable head device **2102**. As shown in FIG. 2D, the plurality of waveguides **2402** can include a first subset of three waveguides **2404** and a second subset of three waveguides **2406**. The two subsets of waveguides **2404**, **2406** can be differentiated by different EPE gratings featuring different grating line curvatures to impart different wavefront curvatures to exiting light. Within each of the subsets of waveguides **2404**, **2406** each waveguide can be used to couple a different spectral channel (e.g., one of red, green and blue spectral channels) to the user's right eye **2206**. (Although not shown in FIG. 2D, the structure of the left eyepiece **2108** is analogous to the structure of the right eyepiece **2110**.)

[0048] FIG. 3A illustrates an example handheld controller component **300** of a mixed reality system **200**. In some examples, handheld controller **300** includes a grip portion **346** and one or more buttons **350** disposed along a top surface **348**. In some examples, buttons **350** may be configured for use as an optical tracking target, e.g., for tracking six-degree-of-freedom (6DOF) motion of the handheld controller **300**, in conjunction with a camera or other optical sensor (which may be mounted in a head unit (e.g., wearable head device **2102**) of mixed reality system **200**). In some examples, handheld controller **300** includes tracking components (e.g., an IMU or other suitable sensors) for detecting position or orientation, such as position or orientation relative to wearable head device **2102**. In some examples, such tracking components may be positioned in a handle of handheld controller **300**, and/or may be mechanically coupled to the handheld controller. Handheld controller **300**

can be configured to provide one or more output signals corresponding to one or more of a pressed state of the buttons; or a position, orientation, and/or motion of the handheld controller **300** (e.g., via an IMU). Such output signals may be used as input to a processor of mixed reality system **200**. Such input may correspond to a position, orientation, and/or movement of the handheld controller (and, by extension, to a position, orientation, and/or movement of a hand of a user holding the controller). Such input may also correspond to a user pressing buttons **350**.

[0049] FIG. 3B illustrates an example auxiliary unit **320** of a mixed reality system **200**. The auxiliary unit **320** can include a battery to provide energy to operate the system **200**, and can include a processor for executing programs to operate the system **200**. As shown, the example auxiliary unit **320** includes a clip **2128**, such as for attaching the auxiliary unit **320** to a user's belt. Other form factors are suitable for auxiliary unit **320** and will be apparent, including form factors that do not involve mounting the unit to a user's belt. In some examples, auxiliary unit **320** is coupled to the wearable head device **2102** through a multiconduit cable that can include, for example, electrical wires and fiber optics. Wireless connections between the auxiliary unit **320** and the wearable head device **2102** can also be used.

[0050] In some examples, mixed reality system **200** can include one or more microphones to detect sound and provide corresponding signals to the mixed reality system. In some examples, a microphone may be attached to, or integrated with, wearable head device **2102**, and may be configured to detect a user's voice. In some examples, a microphone may be attached to, or integrated with, handheld controller **300** and/or auxiliary unit **320**. Such a microphone may be configured to detect environmental sounds, ambient noise, voices of a user or a third party, or other sounds.

[0051] FIG. 4 shows an example functional block diagram that may correspond to an example mixed reality system, such as mixed reality system **200** described above (which may correspond to mixed reality system **112** with respect to FIG. 1). As shown in FIG. 4, example handheld controller **400B** (which may correspond to handheld controller **300** (a "totem")) includes a totem-to-wearable head device six degree of freedom (6DOF) totem subsystem **404A** and example wearable head device **400A** (which may correspond to wearable head device **2102**) includes a totem-to-wearable head device 6DOF subsystem **404B**. In the example, the 6DOF totem subsystem **404A** and the 6DOF subsystem **404B** cooperate to determine six coordinates (e.g., offsets in three translation directions and rotation along three axes) of the handheld controller **400B** relative to the wearable head device **400A**. The six degrees of freedom may be expressed relative to a coordinate system of the wearable head device **400A**. The three translation offsets may be expressed as X, Y, and Z offsets in such a coordinate system, as a translation matrix, or as some other representation. The rotation degrees of freedom may be expressed as sequence of yaw, pitch and roll rotations, as a rotation matrix, as a quaternion, or as some other representation. In some examples, the wearable head device **400A**; one or more depth cameras **444** (and/or one or more non-depth cameras) included in the wearable head device **400A**; and/or one or more optical targets (e.g., buttons **350** of handheld controller **400B** as described above, or dedicated optical targets included in the handheld controller **400B**) can be used for 6DOF tracking. In some examples, the handheld controller **400B** can include a cam-

era, as described above; and the wearable head device **400A** can include an optical target for optical tracking in conjunction with the camera. In some examples, the wearable head device **400A** and the handheld controller **400B** each include a set of three orthogonally oriented solenoids which are used to wirelessly send and receive three distinguishable signals. By measuring the relative magnitude of the three distinguishable signals received in each of the coils used for receiving, the 6DOF of the wearable head device **400A** relative to the handheld controller **400B** may be determined. Additionally, 6DOF totem subsystem **404A** can include an Inertial Measurement Unit (IMU) that is useful to provide improved accuracy and/or more timely information on rapid movements of the handheld controller **400B**.

[0052] In some examples, it may become necessary to transform coordinates from a local coordinate space (e.g., a coordinate space fixed relative to the wearable head device **400A**) to an inertial coordinate space (e.g., a coordinate space fixed relative to the real environment), for example in order to compensate for the movement of the wearable head device **400A** relative to the coordinate system **108**. For instance, such transformations may be necessary for a display of the wearable head device **400A** to present a virtual object at an expected position and orientation relative to the real environment (e.g., a virtual person sitting in a real chair, facing forward, regardless of the wearable head device's position and orientation), rather than at a fixed position and orientation on the display (e.g., at the same position in the right lower corner of the display), to preserve the illusion that the virtual object exists in the real environment (and does not, for example, appear positioned unnaturally in the real environment as the wearable head device **400A** shifts and rotates). In some examples, a compensatory transformation between coordinate spaces can be determined by processing imagery from the depth cameras **444** using a SLAM and/or visual odometry procedure in order to determine the transformation of the wearable head device **400A** relative to the coordinate system **108**. In the example shown in FIG. 4, the depth cameras **444** are coupled to a SLAM/visual odometry block **406** and can provide imagery to block **406**. The SLAM/visual odometry block **406** implementation can include a processor configured to process this imagery and determine a position and orientation of the user's head, which can then be used to identify a transformation between a head coordinate space and another coordinate space (e.g., an inertial coordinate space). Similarly, in some examples, an additional source of information on the user's head pose and location is obtained from an IMU **409**. Information from the IMU **409** can be integrated with information from the SLAM/visual odometry block **406** to provide improved accuracy and/or more timely information on rapid adjustments of the user's head pose and position.

[0053] In some examples, the depth cameras **444** can supply 3D imagery to a hand gesture tracker **411**, which may be implemented in a processor of the wearable head device **400A**. The hand gesture tracker **411** can identify a user's hand gestures, for example by matching 3D imagery received from the depth cameras **444** to stored patterns representing hand gestures. Other suitable techniques of identifying a user's hand gestures will be apparent.

[0054] In some examples, one or more processors **416** may be configured to receive data from the wearable head device's 6DOF headgear subsystem **404B**, the IMU **409**, the SLAM/visual odometry block **406**, depth cameras **444**,

and/or the hand gesture tracker **411**. The processor **416** can also send and receive control signals from the 6DOF totem system **404A**. The processor **416** may be coupled to the 6DOF totem system **404A** wirelessly, such as in examples where the handheld controller **400B** is untethered. Processor **416** may further communicate with additional components, such as an audio-visual content memory **418**, a Graphical Processing Unit (GPU) **420**, and/or a Digital Signal Processor (DSP) audio spatializer **422**. The DSP audio spatializer **422** may be coupled to a Head Related Transfer Function (HRTF) memory **425**. The GPU **420** can include a left channel output coupled to the left source of imagewise modulated light **424** and a right channel output coupled to the right source of imagewise modulated light **426**. GPU **420** can output stereoscopic image data to the sources of image-wise modulated light **424**, **426**, for example as described above with respect to FIGS. **2A-2D**. The DSP audio spatializer **422** can output audio to a left speaker **412** and/or a right speaker **414**. The DSP audio spatializer **422** can receive input from processor **419** indicating a direction vector from a user to a virtual sound source (which may be moved by the user, e.g., via the handheld controller **320**). Based on the direction vector, the DSP audio spatializer **422** can determine a corresponding HRTF (e.g., by accessing a HRTF, or by interpolating multiple HRTFs). The DSP audio spatializer **422** can then apply the determined HRTF to an audio signal, such as an audio signal corresponding to a virtual sound generated by a virtual object. This can enhance the believability and realism of the virtual sound, by incorporating the relative position and orientation of the user relative to the virtual sound in the mixed reality environment—that is, by presenting a virtual sound that matches a user's expectations of what that virtual sound would sound like if it were a real sound in a real environment.

[0055] In some examples, such as shown in FIG. **4**, one or more of processor **416**, GPU **420**, DSP audio spatializer **422**, HRTF memory **425**, and audio/visual content memory **418** may be included in an auxiliary unit **400C** (which may correspond to auxiliary unit **320** described above). The auxiliary unit **400C** may include a battery **427** to power its components and/or to supply power to the wearable head device **400A** or handheld controller **400B**. Including such components in an auxiliary unit, which can be mounted to a user's waist, can limit the size and weight of the wearable head device **400A**, which can in turn reduce fatigue of a user's head and neck.

[0056] While FIG. **4** presents elements corresponding to various components of an example mixed reality system, various other suitable arrangements of these components will become apparent to those skilled in the art. For example, elements presented in FIG. **4** as being associated with auxiliary unit **400C** could instead be associated with the wearable head device **400A** or handheld controller **400B**. Furthermore, some mixed reality systems may forgo entirely a handheld controller **400B** or auxiliary unit **400C**. Such changes and modifications are to be understood as being included within the scope of the disclosed examples.

Environmental Acoustic Persistence

[0057] As described above, a MRE (such as experienced via a mixed reality system, e.g., mixed reality system **112**, which may include components such as a wearable head unit **200**, handheld controller **300**, or auxiliary unit **320** described above) can present audio signals that appear, to a user of the

MRE, to originate at a sound source with an origin coordinate in the MRE. That is, the user may perceive these audio signals as if they are real audio signals originating from the origin coordinate of the sound source.

[0058] In some cases, audio signals may be considered virtual in that they correspond to computational signals in a virtual environment. Virtual audio signals can be presented to a user as real audio signals detectable by the human ear, for example as generated via speakers **2134** and **2136** of wearable head unit **200** in FIG. **2**.

[0059] A sound source may correspond to a real object and/or a virtual object. For example, a virtual object (e.g., virtual monster **132** of FIG. **1C**) can emit an audio signal in a MRE, which is represented in the MRE as a virtual audio signal, and presented to the user as a real audio signal. For instance, virtual monster **132** of FIG. **1C** can emit a virtual sound corresponding to the monster's speech (e.g., dialogue) or sound effects. Similarly, a real object (e.g., real object **122A** of FIG. **1C**) can be made to appear to emit a virtual audio signal in a MRE, which is represented in the MRE as a virtual audio signal, and presented to the user as a real audio signal. For instance, real lamp **122A** can emit a virtual sound corresponding to the sound effect of the lamp being switched on or off—even if the lamp is not being switched on or off in the real environment. The virtual sound can correspond to a position and orientation of the sound source (whether real or virtual). For instance, if the virtual sound is presented to the user as a real audio signal (e.g., via speakers **2134** and **2136**), the user may perceive the virtual sound as originating from the position of the sound source. Sound sources are referred to herein as “virtual sound sources,” even though the underlying object made to apparently emit a sound may itself correspond to a real or virtual object, such as described above.

[0060] Some virtual or mixed reality environments suffer from a perception that the environments do not feel real or authentic. One reason for this perception is that audio and visual cues do not always match each other in such environments. For example, if a user is positioned behind a large brick wall in a MRE, the user may expect sounds coming from behind the brick wall to be quieter and more muffled than sounds originating right next to the user. This expectation is based on the user's auditory experiences in the real world, where sounds become quiet and muffled when they pass behind large, dense objects. When the user is presented with an audio signal that purportedly originates from behind the brick wall, but that is presented unmuffled and at full volume, the illusion that the sound originates from behind the brick wall is compromised. The entire virtual experience may feel fake and inauthentic, in part because it does not comport with the user's expectations based on real world interactions. Further, in some cases, an “uncanny valley” problem arises, in which even subtle differences between virtual experiences and real experiences can cause heightened feelings of discomfort. It is desirable to improve the user's experience by presenting, in a MRE, audio signals that appear to realistically interact—even in subtle ways—with objects in the user's environment. The more consistent that such audio signals are with the user's expectations, based on real world experience, the more immersive and engaging the user's experience in the MRE can be.

[0061] One way that users perceive and understand the environment around them is through audio cues. In the real world, the real audio signals users hear are affected by where

those audio signals originate from and what objects that audio signals interact with. For example, with all other factors equal, a sound that originates a great distance from a user (e.g., a dog barking in the distance) will appear quieter than the same sound originating from a short distance from the user (e.g., the dog barking in the same room as the user). A user can thus identify a location of a dog in the real environment based in part on the perceived volume of its bark. Likewise, with all other factors equal, a sound that travels away from the user (e.g., the voice of a person who is facing away from the user) will appear less clear and more muffled (i.e., low-pass filtered) than the same sound traveling toward the user (e.g., the voice of a person who is facing toward the user). A user can thus identify the orientation of a person in the real environment based on the perceived characteristics of that person's voice.

[0062] A user's perception of real audio signals can also be affected by the presence of objects in the environment with which audio signals interact. That is, a user may perceive not only an audio signal generated by a sound source, but also the reflections of that audio signal against nearby objects and the reverberation signature imparted by the surrounding acoustic space. For example, if a person speaks in a small room with close walls, those walls may cause short, natural reverberated signals to result as the person's voice reflects off of the walls. A user may infer from those reverberations that they are in a small room with close walls. Likewise, a large concert hall or cathedral may cause longer reverberations, from which the user may infer that they are in a large, spacious room. Similarly, reverberations of audio signals may take on various sonic characteristics based on the position or orientation of the surfaces against which those signals reflect, or the materials of those surfaces. For example, reverberations against tiled walls will sound different than reverberations against brick, carpet, drywall, or other materials. These reverberation characteristics can be used by the user to understand—acoustically—the size, shape, and material composition of the space they inhabit.

[0063] The above examples illustrate how audio cues can inform a user's perception of the environment around them. These cues can act in combination with visual cues: for example, if the user sees a dog in the distance, the user may expect the sound of that dog's bark to be consistent with that distance (and may feel disconcerted or disoriented if it is not, as in some virtual environments). In some examples, such as in low-light environments, or with respect to visually impaired users, visual cues may be limited or unavailable; in such cases, audio cues may take on a particular importance, and may serve as the user's primary means of understanding their environment.

[0064] A system architecture may be beneficial to organize, store, recall, and/or manage information needed to present realistic virtual audio. For example, a MR system (e.g., MR system **112, 200**) may manage environmental information like what real environment a user may be in, what acoustic properties that real environment may have, and/or where in that real environment the user may be located. A MR system may further manage information regarding objects in the real and/or virtual environment (e.g., objects that may affect the general acoustic properties of a real environment and/or objects that may affect acoustic properties of a virtual sound source interacting with the objects). A MR system may also manage information

regarding virtual sound sources. For example, where a virtual sound source is located may be relevant in rendering realistic virtual audio.

[0065] In addition to managing a virtual audio system, it may be necessary to manage other systems simultaneously to present a full MR experience. For example, a full MR experience may require a virtual visuals system, which may manage information used to render virtual objects. A full MR experience may require a simultaneous localization and mapping system ("SLAM"), which may construct, update, and/or maintain a three-dimensional model of a user's environment. A MR system (e.g., MR system **112, 200**) may manage these systems and more, in addition to a virtual audio system, to present a full MR experience. A virtual audio system architecture may be helpful to manage interactions between these systems to facilitate data transfer, management, storage, and/or security.

[0066] In some embodiments, a system (e.g., a virtual audio system) may interact with other, higher-level systems. In some embodiments, a lower-level system (e.g., a virtual audio system) may more closely interact with hardware-level inputs and/or outputs, whereas a higher-level system (e.g., an application) may interface with a lower-level system. A higher-level system may utilize lower-level systems to execute their function (e.g., a game application may rely on a lower-level virtual audio system to render realistic virtual audio). A virtual audio system may benefit from a system architecture designed to manage interactions with higher-level systems while maintaining the integrity of the virtual audio system. For example, multiple higher-level systems (e.g., multiple third-party applications) may interface with a virtual audio system at the same or substantially the same time. In some embodiments, it may be more computationally efficient to maintain a single virtual audio system that can render virtual audio than to have each higher-level system maintain a separate audio system. For instance, in some embodiments, a single digital reverberator may be used to process sound objects from multiple higher-level systems when those objects are intended to be in the same virtual or real acoustical space (e.g., the room the user is in). A well-designed system architecture may also protect the integrity of information that may be used in other applications (e.g., from data corruption and/or tampering).

[0067] In some embodiments, it can be advantageous to design a system architecture such that changes can be made in real-time without disrupting service to other systems (e.g., higher-level systems). For example, a virtual audio system may store, maintain, or otherwise manage an audio model that accounts for acoustic properties of a real environment (e.g., a room). If a user changes real environments (e.g., moves to a different room), the audio model may be updated to account for the change in the real environment. If the MR system is currently in use (e.g., a MR system is presenting virtual visuals and/or virtual audio to the user), it may be necessary to update the audio model when a different system (e.g., a higher-level system) is still using the audio model to render virtual audio.

[0068] In some embodiments, it can be advantageous to design a system architecture to propagate changes in other systems. For example, some systems may maintain a separate copy of an audio model, or some systems may store a particular repeated sound effect rendered using an audio model maintained by a virtual audio system. It may therefore be advantageous to propagate changes made in a virtual

audio system to other systems. For example, if a user changes environments (e.g., moves rooms) and a new audio model may be more accurate, a virtual audio system may modify its audio model and notify any clients (e.g., systems that use and/or rely on the virtual audio system) of changes. In some embodiments, clients may then query virtual audio system and update internal data accordingly.

[0069] FIG. 5 illustrates an exemplary virtual audio system, according to some embodiments. Virtual audio system 500 can include persistence module 502. A module (e.g., persistence module 502) can include one or more computer systems configured to execute instructions and/or store one or more data structures. In some embodiments, a module (e.g., persistence module 502) can be configured to execute a process, sub-process, thread, and/or service managed by audio service 522 (e.g., instructions executed by persistence module 502 may run within audio service 522), which may run on one or more computer systems. In some embodiments, audio service 522 can be a process, which may run in a run-time environment, and instructions executed by a module (e.g., persistence module 502) may be a component of audio service 522 (e.g., instructions executed by persistence module 502 may be a sub-process of audio service 522). In some embodiments, audio service 522 can be a sub-process of a parent process. Instructions executed by a module (e.g., persistence module 502) can include one or more components (e.g., a process, sub-process, thread, and/or service executed by localization status sub-module 506, acoustical data sub-module 508, and/or audio model sub-module 510). In some embodiments, instructions executed by a module (e.g., persistence module 502) may run as a sub-process of audio service 522 and/or as a separate process in a different location than other components of audio service 522. For example, instructions executed by a module (e.g., persistence module 502) may run in a general-purpose processor, and one or more other components of audio service 522 may run in an audio-specific processor (e.g., a DSP). In some embodiments, instructions executed by a module (e.g., persistence module 502) may run in a different process address space and/or memory space than other components of audio service 522. In some embodiments, instructions executed by a module (e.g., persistence module 502) may run as one or more threads within audio service 522. In some embodiments, instructions executed by a module (e.g., persistence module 502) may be instantiated within audio service 522. In some embodiments, instructions executed by a module (e.g., persistence module 502) may share a process address and/or memory space with other components of audio service 522.

[0070] In some embodiments, persistence module 502 can include localization status sub-module 506. Localization status sub-module 506 can include one or more computer systems configured to execute instructions and/or store one or more data structures. For example, instructions executed by localization status sub-module 506 can be a sub-process of persistence module 502. In some embodiments, localization status sub-module 506 can indicate whether localization has been achieved (e.g., localization status sub-module 506 may indicate whether a MR system has identified a real environment and/or located itself within the real environment). In some embodiments, localization status sub-module 506 can interface (e.g., via an API) with a localization system. A localization system may determine a location for a MR system (and/or a user using a MR system). In some

embodiments, a localization system can utilize techniques like SLAM to create a three-dimensional model of a real environment and estimate a system's (and/or a user's) location within the environment. In some embodiments, a localization system can rely on a passable world system (described in further detail below) and one or more sensors (e.g., of MR system 112, 200) to estimate a MR system's (and/or a user's) location within an environment. In some embodiments, localization status sub-module 506 can query a localization system to determine if localization is currently achieved for a MR system. Similarly, a localization system may notify localization status sub-module 506 of a successful localization. A localization status (e.g., of a MR system 112, 200) may be used to determine whether an audio model should be updated (e.g., because a user's real environment has changed).

[0071] In some embodiments, persistence module 502 can include acoustical data sub-module 508. Acoustical data sub-module 508 can include one or more computer systems configured to execute instructions and/or store one or more data structures. For example, instructions executed by acoustical data sub-module 508 may be a sub-process of persistence module 502. In some embodiments, acoustical data sub-module 508 may store one or more data structures representing acoustical data that may be used to create an audio model. In some embodiments, acoustical data sub-module 508 can interface (e.g., via an API) with a passable world system. A passable world system may include information on known real environments (e.g., rooms, buildings, and/or outside spaces) and associated real and/or virtual objects. In some embodiments, a passable world system may include persistent coordinate frames and/or anchor points. A persistent coordinate frame and/or an anchor point can be a point fixed in space that may be known to a MR system (e.g., by a unique identifier). Virtual objects may be positioned in relation to one or more persistent coordinate frames and/or anchor points to enable object persistence (e.g., a virtual object can appear to remain in the same location in a real environment regardless of who is viewing the virtual object and regardless of any movement of a user). Persistent coordinate frames and/or anchor points can be especially advantageous when two or more users with separate MR systems utilize different world coordinate frames (e.g., each user's location is designated as an origin for their respective world coordinate frame). Object persistence across users can be achieved by translating between an individual world coordinate frame and a universal persistent coordinate frame and placing/referencing virtual objects in relation to a persistent coordinate frame. In some embodiments, a passable world system can manage and maintain persistent coordinate frames by, for example, mapping new areas and creating new persistent coordinate frames; by re-mapping known areas and reconciling new persistent coordinate frames with previously determined persistent coordinate frames; and/or associating persistent coordinate frames with identifiable information (e.g., a location and/or nearby objects). In some embodiments, acoustical data sub-module 508 may query a separate system (e.g., a passable world system) for one or more persistent coordinate frames. In some embodiments, acoustical data sub-module 508 can retrieve relevant persistent coordinate frames (e.g., persistent coordinate frames within a threshold radius of a user's position) to facilitate access and management, including creation, modification, and/or deletion of associated acoustical data.

[0072] In some embodiments, acoustical data stored in acoustical data sub-module **508** can be organized into physically-correlated modular units (e.g., a room may be represented by a modular unit, and a chair within the room may be represented by another modular unit). For example, a modular unit may include physical and/or perceptually relevant properties of a physical environment (e.g., a room). Physical and/or perceptually relevant properties can include properties that may affect a room's acoustic characteristics (e.g., dimensions and/or a shape of the room). In some embodiments, physical and/or perceptually relevant properties can include functional and/or behavioral properties, which may be interpreted by a rendering engine (e.g., whether sources outside of the room should be occluded or not). In some embodiments, physical and/or perceptually relevant properties can include properties of known and/or recognized objects. For example, geometry of fixed (e.g., a floor, a wall, furniture, etc.) and/or movable (e.g., a mug) objects may be stored as physical and/or perceptually relevant properties and may be associated with a particular environment. In some embodiments, physical and/or perceptually relevant properties can include transmission loss, scattering coefficients, and/or absorption coefficients. In some embodiments, a modular unit can include physical and/or perceptually relevant linkages (e.g., between other modular units or within a modular unit). For example, a physical and/or perceptually relevant linkage may link together two or more rooms and describe how the rooms may interact with each other (e.g., cross-coupling gain levels between the digital reverberators simulating the rooms and/or line of sight paths between the two spaces).

[0073] In some embodiments, physical and/or perceptually relevant properties can include acoustic properties like a reverberation time, reverberation delay, and/or reverberation gain. A reverberation time may include a length of time required for a sound to decay by a certain amount (e.g., by 60 decibels). Sound decay can be a result of sound reflecting off surfaces in a real environment (e.g., walls, floors, furniture, etc.) whilst losing energy due to, for example, sound absorption by a room's boundaries (e.g., walls, floors, ceiling, etc.), objects inside the room (e.g., chairs, furniture, people, etc.), and the air in the room. A reverberation time can be influenced by environmental factors. For example, absorbent surfaces (e.g., cushions) may absorb sound in addition to geometric spreading, and a reverberation time may be reduced as a result. In some embodiments, it may not be necessary to have information about an original source to estimate an environment's reverberation time. A reverberation gain can include a ratio of a sound's direct/source/original energy to the sound's reverberation energy (e.g., energy of a reverberation resulting from the direct/source/original sound) where a listener and the source are substantially co-located (e.g., a user may clap their hands, producing a source sound that may be considered substantially co-located with one or more microphones mounted on a head-wearable MR system). For example, an impulse (e.g., a clap) may have an energy associated with the impulse, and the reverberation sound from the impulse may have an energy associated with the reverberation of the impulse. The ratio of the original/source energy to the reverberation energy may be a reverberation gain. A real environment's reverberation gain may be influenced by, for example, absorbent surfaces that can absorb sound and thereby reduce a reverberation energy.

[0074] In some embodiments, acoustical data can include metadata (e.g., metadata of physical and/or perceptually relevant properties). For example, information about when and/or where acoustical data was gathered may be included in acoustical data. In some embodiments, confidence data (e.g., an estimated measurement accuracy and/or a count of repeated measurements) associated with acoustical data may be included as metadata. In some embodiments, a type of modular unit (e.g., a modular unit for a room or a linkage between modular units) and/or data versioning may be included as metadata. In some embodiments, a unique identifier associated with acoustical data, persistent coordinate frame, and/or an anchor point may be included as metadata. In some embodiments, a relative transform from a persistent coordinate frame and/or an anchor point and an associated virtual object may be included as metadata. In some embodiments, metadata can be stored with acoustical data as a single bundle.

[0075] In some embodiments, acoustical data may be organized by persistent coordinate frames and/or anchor points, and persistent coordinate frames and/or anchor points may be organized into maps. In some embodiments, an audio model may account for acoustic data organized by persistent coordinate frames and/or anchor points, which may correspond to locations within an environment. In some embodiments, acoustical data may be loaded into acoustical data sub-module **508** upon a successful localization event (which may be indicated by localization status sub-module **506**). In some embodiments, all available acoustical data may be loaded into acoustical data sub-module **508**. In some embodiments, only relevant acoustical data may be loaded into acoustical data sub-module **508** (e.g., acoustical data for persistent coordinate frames and/or anchor points within a certain distance of a MR system's location).

[0076] In some embodiments, acoustical data can include different states that may change according to changes in a real environment. For example, acoustical data for a given modular unit which may represent a room may include acoustical data for the room in an empty state and acoustical data for the room in an occupied state. In some embodiments, changes in a room's furniture arrangement may be reflected by a change of state in acoustical data associated with the room. In some embodiments, a modular unit (e.g., representing a room) may include different acoustical data for states when a door is open or closed. States can be represented as binary values (e.g., 0 or 1) or continuous values (e.g., how open a door is, how occupied a room is, etc.).

[0077] In some embodiments, persistence module **502** may include audio model sub-module **510**. Audio model sub-module **510** can include one or more computer systems configured to execute instructions and/or store one or more data structures. For example, audio model sub-module **510** may include one or more data structures representing an audio model for a real and/or virtual environment. In some embodiments, the audio model may be generated at least in part by acoustical data stored in acoustical data sub-module **508**. An audio model may represent how sounds behave in a particular environment. For example, virtual sounds generated by a MR system (e.g., MR system **112**, **200**) may be modified by an audio model in audio model sub-module **510** to reflect acoustic characteristics of an environment. A virtual concert presented to a user sitting in a cavernous concert hall may have similar acoustic properties as a real

concert presented in the same concert hall. A MR system may localize itself to an identified concert hall, load relevant acoustical data, and generate an audio model to model acoustical properties of the concert hall.

[0078] In some embodiments, an audio model may be used to model sound propagation in an environment. For example, propagation effects can include occlusion, obstruction, early reflections, diffraction, time-of-flight delay, Doppler effects, and other effects. In some embodiments, an audio model can account for frequency-dependent absorption and/or transmission loss (e.g., based on acoustical data loaded into acoustical data sub-module **508**). In some embodiments, an audio model stored in audio model sub-module **510** may inform other aspects of an audio engine. For example, an audio model may use acoustical data to procedurally synthesize audio (e.g., collisions between virtual and/or real objects).

[0079] In some embodiments, audio render service **522** may include render track module **514**. Render track module **514** can include one or more computer systems configured to execute instructions and/or store one or more data structures. For example, render track module **514** may include audio information that may later be presented to a user. In some embodiments, a MR system may present a virtual sound that includes several sound sources mixed together (e.g., a sound source of two swords colliding and a sound source of a person yelling). Render track module **514** may store one or more tracks that may be mixed with other tracks to present to a user. In some embodiments, render track module **514** can include information about spatial sources. For example, render track module **514** may include information about where a sound source is located, which may be accounted for in an audio model and/or rendering algorithm. In some embodiments, render track module **514** may include information about relationships between modular units and/or sound sources. For example, one or more render tracks and/or audio models may be associated together as a single group.

[0080] In some embodiments, audio render service **522** may include a location manager module **516**. Location manager module **516** can include one or more computer systems configured to execute instructions and/or store one or more data structures. For example, location manager module **516** may manage location information relevant to an audio engine (e.g., a current location of a MR system in a real environment). In some embodiments, location manager module **516** can include a perception wrapper sub-module. A perception wrapper sub-module may be a wrapper around perception data (e.g., what a MR system has detected or is detecting). In some embodiments, the perception wrapper may interface and/or translate between perception data and location manager module **516**. In some embodiments, location manager module **516** may include a head-pose sub-module, which may include head-pose data. Head-pose data may include a location and/or orientation of a MR system (or a corresponding user) in a real environment. In some embodiments, the head-pose may be determined based on the perception data.

[0081] In some embodiments, audio render service **522** may include audio model module **518**. Audio model module **518** can include one or more computer systems configured to execute instructions and/or store one or more data structures. For example, audio model module **518** may include an audio model, which may be the same audio model included

in audio model sub-module **510**. In some embodiments, modules **510** and **518** may maintain duplicate copies of the same audio model. It can be advantageous to maintain more than one copy of an audio model when, for example, an audio model is being updated, but a sound should be presented to a user. It can be advantageous to update a copy of a model when the model is currently in use, and then update the outdated model when the outdated model becomes available (e.g., is no longer in use). In some embodiments, an audio model can be transferred between modules **510** and **518** through serialization. The audio model in module **510** can be serialized and de-serialized to facilitate data transfer to module **518**. Serialization can facilitate data transfer between processors (e.g., a general processor and an audio-specific processor) so that typed memory does not need to be shared.

[0082] In some embodiments, audio render service **522** can include rendering algorithm module **520**. Rendering algorithm module **520** can include one or more computer systems configured to execute instructions and/or store one or more data structures. For example, rendering algorithm module **520** can include an algorithm to render virtual sounds so that they can be presented to a user (e.g., via one or more speakers of a MR system). Rendering algorithm module **520** may account for an audio model of a specific environment (e.g., an audio model in module **510** and/or **518**).

[0083] In some embodiments, audio service **522** can be a process, sub-process, thread, and/or service running on one or more computer systems (e.g., in MR system **112**, **200**). In some embodiments, a separate system (e.g., a third-party application) may request that an audio signal be presented (e.g., via one or more speakers of MR system **112**, **200**). Such a request may take any suitable form. In some embodiments, a request that an audio signal be presented can include a software instruction to present the audio signal; in some embodiments, such a request may be hardware-driven. Requests may be issued with or without user involvement. Further, such requests may be received via local hardware (e.g., from the MR system itself), via external hardware (e.g., a separate computer system in communication with the MR system), via the internet (e.g., via a cloud server), or via any other suitable source or combination of sources. In some embodiments, audio service **522** may receive the request, render a requested audio signal (e.g., through rendering algorithm **520**, which may account for an audio model from block **510** and/or **518**), and present the requested audio signal to a user. In some embodiments, audio service **522** may be a process that continually runs (e.g., in the background) while an operating system of a MR system is running. In some embodiments, audio service **522** can be an instantiation of a parent background service, which may serve as a host process to one or more background processes and/or sub-processes. In some embodiments, audio service **522** may be part of an operating system of a MR system. In some embodiments, audio service **522** may be accessible to applications that may run on the MR system. In some embodiments, a user of a MR system may not directly provide inputs to audio service **522**. For example, a user may provide an input (e.g., a movement command) to an application (e.g., a role-playing game) running on a MR system. The application may provide inputs to audio service **522** (e.g., to render the sound of footsteps), and audio service **522**

may provide outputs (e.g., the rendered sound of footsteps) to the user (e.g., via a speaker) and/or to other processes and/or services.

[0084] FIG. 6 illustrates an exemplary process for updating an audio model, according to some embodiments. At step 606, a localization may be determined (e.g., a MR system may successfully identify its location within an environment). At step 607, which may occur within a persistence module 602 (which may correspond with persistence module 502), a notification of a successful localization may issue. In some embodiments, a notification of a successful localization may trigger a process to update an audio model (e.g., because the previous audio model may no longer apply to the current location).

[0085] At step 608, it can be determined whether to initiate a recall of acoustical data. It can be desirable to set one or more conditions for initiating recall so that an audio model is not updated too often. For example, if a user using a MR system moves only slightly within a room, it may not be desirable to update an audio model (e.g., because an updated model may not be perceptually distinguishable from the existing model, and/or it may be computationally expensive to continually update the model). In some embodiments, a threshold condition at step 608 may be based on time. For example, a recall may be initiated only if a recall has not already been initiated in the previous 5 seconds. In some embodiments, a threshold condition at step 608 may be based on localization. For example a recall may only be initiated if a user has changed positions by a threshold amount of distance. It should be noted that other threshold conditions may be used as well. In some embodiments, steps 607 and/or 608 may occur within a localization status sub-module (e.g., localization status sub-module 506).

[0086] If it is determined that a recall should be initiated, persistent coordinate frames may be retrieved at step 610. In some embodiments, only a subset of available persistent coordinate frames may be retrieved at step 610. For example, only persistent coordinate frames near a localization may be retrieved.

[0087] At step 612, acoustical data may be retrieved. In some embodiments, the acoustical data retrieved at step 612 may correspond with acoustical data stored in acoustical data sub-module 508. In some embodiments, only a subset of available acoustical data may be retrieved at step 612. For example, acoustical data associated with one or more persistent coordinate frames and/or anchor points may be retrieved. In some embodiments, steps 612 and/or 614 may occur within an acoustical data sub-module (e.g., acoustical data sub-module 508).

[0088] At step 614, an audio model may be constructed and/or modified. In some embodiments, the audio model may account for acoustical data retrieved at step 612, and the audio model may model acoustic characteristics of a particular environment. In some embodiments, step 614 may occur within an audio model sub-module (e.g., audio model sub-module 510).

[0089] At step 616, it can be determined if copies of the audio model should be updated. It may be desirable to set one or more conditions for updating copies of the audio model to avoid disrupting services (e.g., presenting audio to a user). For example, one condition may evaluate whether copies of the audio model exist (e.g., within audio render service 604 but outside of persistence module 602). If no copies of the audio model exist, the audio model may be

retrieved by audio render service 604 (which may correspond to audio render service 522). In some embodiments, a condition may evaluate whether a copy of an audio model is currently in use (e.g., whether the audio model is being used to render audio to present to a user). If the copy of the audio model is not in use, the updated audio model (e.g., the audio model generated at step 614) may be propagated to the copy.

[0090] At step 618, audio render service 604 may retrieve a copy of an audio model (e.g., an audio model generated at step 614). The audio model may be transferred using data serialization and/or de-serialization.

[0091] At step 620, an outdated audio model may be optionally deleted and/or disabled. For example, audio render service 604 may have a first, existing audio model which it has previously been using. The audio render service 604 may retrieve a second, updated audio model (e.g., from persistence module 602) and delete and/or disable the first, existing audio model.

[0092] At step 622, a notification may be issued of a new audio model. In some embodiments, a notification may include a callback function to clients (e.g., third-party applications) who may be subscribed to hear when the audio model changes.

[0093] FIG. 7 illustrates an exemplary process for updating an audio model, according to some embodiments. At step 706, audio data may be received (e.g., via one or more sensors of MR system 112, 200). In some embodiments, audio data may be manually entered (e.g., a user and/or a developer may manually enter a reverberation time, reverberation delay, reverberation gain, etc.). At step 708, which may occur in persistence module 702 (which may correspond with persistence module 502), an associated environment may be identified. An associated environment may be identified by metadata that may accompany the audio data (e.g., the metadata may carry information about one or more persistent coordinate frames and/or anchor points which may be known to a MR system).

[0094] At step 710, it can be determined if the associated environment is new. For example, if an associated environment may not be identified and/or is associated with unknown identifiers, it may be determined that the audio data is associated with a new environment. If it is determined that an associated environment is not new, a copy of the official audio model may be updated (e.g., with room properties that may be derived from the audio data). If it is determined that the associated environment is new, a new environment may be added to a copy of the official audio model and the copy audio model may be updated accordingly. In some embodiments, the new environment may be represented by a new modular unit.

[0095] At step 716, metadata associated with the new environment (e.g., metadata associated with the new modular unit) may be initialized. For example, metadata associated with a measurement count, confidence, or other information may be created and bundled with the new modular unit.

[0096] At step 718, the official audio model within persistence module 702 may be updated. For example, the official audio model may be duplicated from an updated copy audio model. In some embodiments, the official audio model may be locked at step 718 to prevent further changes being made to the official audio model. In some embodiments, changes may still be made to copies of the official

audio model (that may still exist within persistence module 702) while the official audio model is locked.

[0097] At step 720, acoustical data associated with the new audio data may be saved. For example, a new modular unit associated with a new room may be saved and/or passed to a passable world system (which may make it accessible in the future to MR systems as needed). In some embodiments, step 720 may occur within acoustical data sub-module 508. In some embodiments, step 720 may occur sequentially following step 718. In some embodiments, step 720 may occur at an independent time as determined by other components, for example, based on the availability of a passable world system in which acoustical data may be saved.

[0098] At step 722, audio render service 704 (which may correspond to audio render service 522) may retrieve a copy of an audio model. In some embodiments, the copy of the audio model may be the same audio model updated at step 718. In some embodiments, the data transfer can occur through serialization and de-serialization. In some embodiments, an audio model may be locked while a serialization process is executed, which may prevent the audio model from changing while a snapshot of the audio model is created.

[0099] At step 724, an outdated copy of an audio model may be deleted and/or disabled.

[0100] At step 726, a notification may be issued regarding the new audio model. The notification can be a callback function to clients subscribed to hear when the model is updated.

[0101] At step 728, the official audio model may be released, which may indicate that a serialized bundle corresponding to the audio model may be deleted. In some embodiments, it may be desirable to lock the official audio model within persistence module 702 while a copy of the official audio model is being transferred to audio render service 704. It may be desirable to release the lock of the official audio model once audio render service 704 has finished retrieving a copy of the official audio model so that the official audio model can continue to update.

[0102] In some embodiments, audio render service (e.g., audio render service 522) may not manage interactions between a persistence module (e.g., persistence module 502) and a rendering algorithm (e.g., rendering algorithm module 520). For example, rendering algorithm 520 may communicate directly with persistence module 502 to retrieve an updated audio model. In some embodiments, rendering algorithm 520 may include its own copy of the audio model. In some embodiments, rendering algorithm 520 may access an audio model within persistence module 502.

[0103] As provided above, disclosed herein are systems and methods for storing, organizing, and maintaining acoustic data for mixed reality systems.

[0104] A system may include one or more sensors of a head-wearable device, a speaker of the head-wearable device, and one or more processors configured to execute a method. The method for execution by the one or more processors may include: receiving a request to present an audio signal; identifying, via the one or more sensors of the head-wearable device, an environment; retrieving one or more audio model components associated with the environment; generating a first audio model based on the audio model components; generating a second audio model based on the first audio model; determining a modified audio signal based on the second audio model and based on the

request to present an audio signal; and presenting, via the speaker of the head-wearable device, the modified audio signal.

[0105] In some system aspects, the second audio model may be generated by an audio service. In some system aspects, the modified audio signal may be determined by an audio service. In some system aspects, the second audio model may be a duplicate of the first audio model.

[0106] In some system aspects, the one or more audio model components may include one or more dimensions of the environment. In some system aspects, the one or more audio model components may include a reverberation time. In some system aspects, the one or more audio model components may include a reverberation gain. In some system aspects, the one or more audio model components may include a transmission loss coefficient. In some system aspects, the one or more audio model components may include an absorption coefficient.

[0107] A method may include receiving a request to present an audio signal. An environment may be identified via one or more sensors of a head-wearable device. One or more audio model components associated with the environment may be retrieved. A first audio model based on the audio model components may be generated. A second audio model may be generated based on the first audio model. A modified audio signal may be determined based on the second audio model and based on the request to present an audio signal. The modified audio signal may be presented via a speaker of the head-wearable device.

[0108] In some method aspects, the second audio model may be generated by an audio service. In some method aspects, the modified audio signal may be determined by an audio service. In some method aspects, the second audio model may be a duplicate of the first audio model.

[0109] In some method aspects, the one or more audio model components may include one or more dimensions of the environment. In some method aspects, the one or more audio model components may include a reverberation time. In some method aspects, the one or more audio model components may include a reverberation gain. In some method aspects, the one or more audio model components may include a transmission loss coefficient. In some method aspects, the one or more audio model components may include an absorption coefficient.

[0110] A non-transitory computer-readable medium may store instructions that, when executed by one or more processors, cause the one or more processors to execute a method. The method for execution by the one or more processors may include: receiving a request to present an audio signal; identifying, via one or more sensors of a head-wearable device, an environment; retrieving one or more audio model components associated with the environment; generating a first audio model based on the audio model components; generating a second audio model based on the first audio model; determining a modified audio signal based on the second audio model and based on the request to present an audio signal; and presenting, via a speaker of the head-wearable device, the modified audio signal.

[0111] In some non-transitory computer-readable medium aspects, the second audio model may be generated by an audio service. In some non-transitory computer-readable medium aspects, the modified audio signal may be determined by an audio service. In some non-transitory com-

puter-readable medium aspects, the second audio model may be a duplicate of the first audio model.

[0112] In some non-transitory computer-readable medium aspects, the one or more audio model components may include one or more dimensions of the environment. In some non-transitory computer-readable medium aspects, the one or more audio model components may include a reverberation time. In some non-transitory computer-readable medium aspects, the one or more audio model components may include a reverberation gain. In some non-transitory computer-readable medium aspects, the one or more audio model components may include a transmission loss coefficient. In some non-transitory computer-readable medium aspects, the one or more audio model components may include an absorption coefficient.

[0113] A system may include one or more sensors of a head-wearable device, a speaker of the head-wearable device, and one or more processors configured to execute a method. The method for execution by the one or more processors may include: receiving, via the one or more sensors of the head-mounted wearable device, audio data; determining one or more acoustic characteristics of an environment based on the audio data; determining an associated environment for the audio data; generating an updated audio model based on the one or more acoustic characteristics of the environment; retrieving the updated audio model; generating a notification associated with the updated audio model; presenting, via the speaker of the head-wearable device, an audio signal based on the updated audio model.

[0114] In some system aspects, the updated audio model may be retrieved by an audio service. In some system aspects, the notification may be generated by an audio service. In some system aspects, generating the updated audio model may be further based on a previous audio model.

[0115] In some system aspects, the one or more acoustic characteristics of the environment may include one or more dimensions of the environment. In some system aspects, the one or more acoustic characteristics of the environment may include a reverberation time. In some system aspects, the one or more acoustic characteristics of the environment may include a reverberation gain. In some system aspects, the one or more acoustic characteristics of the environment may include a transmission loss coefficient. In some system aspects, the one or more acoustic characteristics of the environment may include an absorption coefficient.

[0116] A method may include receiving, via one or more sensors of a head-wearable device, audio data. One or more acoustic characteristics of an environment may be determined based on the audio data. An associated environment may be determined for the audio data. An updated audio model may be generated based on the one or more acoustic characteristics of the environment. The updated audio model may be retrieved. A notification associated with the updated audio model may be generated. An audio signal based on the updated audio model may be presented via a speaker of the head-wearable device.

[0117] In some method aspects, the updated audio model may be retrieved by an audio service. In some method aspects, the notification may be generated by an audio service. In some method aspects, generating the updated audio model may be further based on a previous audio model.

[0118] In some method aspects, the one or more acoustic characteristics of the environment may include one or more dimensions of the environment. In some method aspects, the one or more acoustic characteristics of the environment may include a reverberation time. In some method aspects, the one or more acoustic characteristics of the environment may include a reverberation gain. In some method aspects, the one or more acoustic characteristics of the environment may include a transmission loss coefficient. In some method aspects, the one or more acoustic characteristics of the environment may include an absorption coefficient.

[0119] A non-transitory computer-readable medium may store instructions that, when executed by one or more processors, cause the one or more processors to execute a method. The method for execution by the one or more processors may include: receiving, via one or more sensors of a head-wearable device, audio data; determining one or more acoustic characteristics of an environment based on the audio data; determining an associated environment for the audio data; generating an updated audio model based on the one or more acoustic characteristics of the environment; retrieving the updated audio model; generating a notification associated with the updated audio model; and presenting, via a speaker of the head-wearable device, an audio signal based on the updated audio model.

[0120] In some non-transitory computer-readable medium aspects, the updated audio model may be retrieved by an audio service. In some non-transitory computer-readable medium aspects, the notification may be generated by an audio service. In some non-transitory computer-readable medium aspects, generating the updated audio model may be further based on a previous audio model.

[0121] In some non-transitory computer-readable medium aspects, the one or more acoustic characteristics of the environment may include one or more dimensions of the environment. In some non-transitory computer-readable medium aspects, the one or more acoustic characteristics of the environment may include a reverberation time. In some non-transitory computer-readable medium aspects, the one or more acoustic characteristics of the environment may include a reverberation gain. In some non-transitory computer-readable medium aspects, the one or more acoustic characteristics of the environment may include a transmission loss coefficient. In some non-transitory computer-readable medium aspects, the one or more acoustic characteristics of the environment may include an absorption coefficient.

[0122] Although the disclosed examples have been fully described with reference to the accompanying drawings, it is to be noted that various changes and modifications will become apparent to those skilled in the art. For example, elements of one or more implementations may be combined, deleted, modified, or supplemented to form further implementations. Such changes and modifications are to be understood as being included within the scope of the disclosed examples as defined by the appended claims.

1. A system comprising:

one or more sensors of a head-wearable device;
a speaker of the head-wearable device; and

one or more processors configured to perform a method comprising:

- identifying an audio model associated with a location of the head-wearable device at a first time, wherein the audio model was updated at a second time before the first time;
 - in accordance with a determination that a difference between the first time and the second time is not less than a threshold amount of time;
 - determining, via the one or more sensors of the head-wearable device, one or more acoustic characteristics of an environment of the head-wearable device; and
 - presenting, via the speaker of the head-wearable device, a first audio signal based on an updated audio model, wherein the updated audio model is generated based on the one or more acoustic characteristics of the environment; and
 - in accordance with a determination that the difference between the first time and the second time is less than the threshold amount of time;
 - presenting, via the speaker of the head-wearable device, a second audio signal based on the audio model.
2. The system of claim 1, wherein the method further comprises receiving the audio model at the head-wearable device via an audio service.
 3. The system of claim 1, wherein the method further comprises generating, via an audio service, a notification associated with the updated audio model.
 4. The system of claim 1, wherein the generating the updated audio model comprises generating the updated audio model based on a previous audio model.
 5. The system of claim 1, wherein the one or more acoustic characteristics of the environment comprises one or more dimensions of the environment.
 6. The system of claim 1, wherein the one or more acoustic characteristics of the environment comprises a reverberation time.
 7. The system of claim 1, wherein the one or more acoustic characteristics of the environment comprises a reverberation gain.
 8. The system of claim 1, wherein the one or more acoustic characteristics of the environment comprises a transmission loss coefficient.
 9. The system of claim 1, wherein the one or more acoustic characteristics of the environment comprises an absorption coefficient.
 10. The system of claim 1, wherein the method further comprises determining, via the one or more sensors of the head-wearable device, the location of the head-wearable device.
 11. The system of claim 1, wherein the identifying the audio model comprises determining whether the location of the head-wearable device is within a threshold distance from a location associated with the audio model.
 12. The system of claim 1, wherein the method further comprises:
 - in accordance with the determination that the difference between the first time and the second time is not less than the threshold amount of time, rendering the first audio signal via the updated audio model, and
 - in accordance with the determination that the difference between the first time and the second time is less than the threshold amount of time, rendering the second audio signal via the audio model.

13. The system of claim 1, wherein the updated audio model is associated with a second location, different from the location of the head-wearable device at the first time.
14. The system of claim 1, wherein in accordance with the determination that the difference between the first time and the second time is not less than the threshold amount of time, a copy of the updated audio model is generated based on the one or more acoustic characteristics of the environment.
15. The system of claim 1, wherein the second audio signal is presented based on a copy of the updated audio model.
16. A method comprising:
 - identifying an audio model associated with a location of a head-wearable device at a first time, wherein the audio model was updated at a second time before the first time;
 - in accordance with a determination that a difference between the first time and the second time is not less than a threshold amount of time;
 - determining, via one or more sensors of the head-wearable device, one or more acoustic characteristics of an environment of the head-wearable device; and
 - presenting, via a speaker of the head-wearable device, a first audio signal based on an updated audio model, wherein the updated audio model is generated based on the one or more acoustic characteristics of the environment; and
 - in accordance with a determination that the difference between the first time and the second time is less than the threshold amount of time;
 - presenting, via the speaker of the head-wearable device, a second audio signal based on the audio model.
17. The method of claim 16, further comprising:
 - in accordance with the determination that the difference between the first time and the second time is not less than the threshold amount of time, rendering the first audio signal via the updated audio model, and
 - in accordance with the determination that the difference between the first time and the second time is less than the threshold amount of time, rendering the second audio signal via the audio model.
18. The method of claim 16, wherein in accordance with the determination that the difference between the first time and the second time is not less than the threshold amount of time, a copy of the updated audio model is generated based on the one or more acoustic characteristics of the environment.
19. The method of claim 16, wherein the second audio signal is presented based on a copy of the updated audio model.
20. A non-transitory computer-readable medium storing instructions that, when executed by one or more processors, cause the one or more processors to perform a method comprising:
 - identifying an audio model associated with a location of a head-wearable device at a first time, wherein the audio model was updated at a second time before the first time;
 - in accordance with a determination that a difference between the first time and the second time is not less than a threshold amount of time;

determining, via one or more sensors of the head-wearable device, one or more acoustic characteristics of an environment of the head-wearable device; and

presenting, via a speaker of the head-wearable device, a first audio signal based on an updated audio model, wherein the updated audio model is generated based on the one or more acoustic characteristics of the environment; and

in accordance with a determination that the difference between the first time and the second time is less than the threshold amount of time:

presenting, via the speaker of the head-wearable device, a second audio signal based on the audio model.
