United States Patent	12390346
Kind Code	B2
Date of Patent	August 19, 2025
Inventor(s)	To; John et al.

### Methods of stabilizing an intervertebral scaffolding system

#### Abstract

An intervertebral scaffolding system is provided having a laterovertically-expanding frame operable for a reversible collapse from an expanded state into a collapsed state, the laterovertically-expanding frame having a stabilizer that slidably engages with the distal region of the laterovertically-expanding frame and is configured for retaining the laterovertically-expanding frame from a lateral movement that exceeds the expanded state. The expanded state, for example, can be configured to have an open graft distribution window that at least substantially closes upon the reversible collapse.

## Background/Summary

**CROSS-REFERENCE TO RELATED APPLICATIONS** (1) This application is a continuation of U.S. application Ser. No. 16/932,064, filed Jul. 17, 2020, allowed, which is continuation of U.S. application Ser. No. 15/979,873, filed May 15, 2018, now U.S. Pat. No. 10,758,368, which is a continuation of U.S. application Ser. No. 15/194,463, filed Jun. 27, 2016, now U.S. Pat. No. 9,999,517, which is a continuation of U.S. application Ser. No. 14/701,013, filed Apr. 30, 2015, now U.S. Pat. No. 9,402,733, which is a continuation of U.S. application Ser. No. 14/600,617, filed Jan. 20, 2015, now U.S. Pat. No. 9,060,876, each of which is hereby incorporated herein by reference in its entirety.

### BACKGROUND

#### Field of the Invention

(1) The teachings herein are directed to intervertebral scaffolding systems having a stabilizer for stabilizing and/or retaining support beams upon expansion of the scaffolding in an intervertebral disc space.

#### Description of the Related Art

(2) Bone grafts are used in spinal fusion, for example, which is a technique used to stabilize the

spinal bones, or vertebrae, and a goal is to create a solid bridge of bone between two or more vertebrae. The fusion process includes “arthrodesis”, which can be thought of as the mending or welding together of two bones in a spinal joint space, much like a broken arm or leg healing in a cast. Spinal fusion may be recommended for a variety of conditions that might include, for example, a spondylolisthesis, a degenerative disc disease, a recurrent disc herniation, or perhaps to correct a prior surgery.

(3) Bone graft material is introduced for fusion and a fusion cage can be inserted to help support the disc space during the fusion process. In fact, fusion cages are frequently used in such procedures to support and stabilize the disc space until bone graft unites the bone of the opposing vertebral endplates in the disc space. A transforaminal lumbar interbody fusion (TLIF), for example, involves placement of posterior instrumentation (screws and rods) into the spine, and the fusion cage loaded with bone graft can be inserted into the disc space. Bone graft material can be pre-packed in the disc space or packed after the cage is inserted. TLIF can be used to facilitate stability in the front and back parts of the lumbar spine promoting interbody fusion in the anterior portion of the spine. Fusion in this region can be beneficial, because the anterior interbody space includes an increased area for bone to heal, as well as to handle increased forces that are distributed through this area.

(4) Unfortunately, therein lies a problem solved by the teachings provided herein. Currently available systems can be problematic in that the methods of introducing the fusion cage and bone graft material leaves pockets in regions of the intervertebral space that are not filled with bone graft material, regions in which fusion is desired for structural support. These pockets can create a premature failure of the fused intervertebral space due to forces that are distributed through the regions containing the pockets, for example, when the patient stands and walks.

(5) Traditional fusion cages, such as the Medtronic CAPSTONE cage, are designed to be oversized relative to the disc space to distract the disc space as the entire cage is inserted. However, this makes it difficult to insert and position properly. In response to the problem, the art has developed a number of new fusion cages, such as the Globus CALIBER cage which can be inserted at a low height and expanded vertically to distract the disc space. Unfortunately, these types of devices have the typical graft distribution problem discussed above, in that they do not provide a path for bone graft to be inserted and fill in the space surrounding the cage or within the cage. They have other problems as well, including that the annulotomy must be large to accommodate a large enough cage for stability, and this large opening necessitates more trauma to the patient. Moreover, they can also create the additional problem of “backout”, in that they cannot expand laterally beyond the annulotomy to increase the lateral footprint of the cage relative to lateral dimension of the annulotomy. Since it takes several months for the fusion to occur to completion in a patient, the devices have plenty of time to work their way out of the space through the large annulotomy.

(6) Scaffolding systems may also suffer a lack of stability and/or a lack of a retention of structural components in a desired expansion configuration in the intervertebral space. As such, a multi-component scaffolding system, for example, can benefit from an improved design that adds stability through, for example, (i) enhancing the amount of contact between the scaffolding components upon expansion; and/or (ii) limiting the amount of expansion, or relative movement, that can occur between components upon expansion, or after expansion, in the intervertebral space. Such design considerations can, for example, address the problems of overexpansion of one component relative to another due to, for example, variable stresses that might occur in the intervertebral space upon expansion or after expansion, stresses which can result in at least partial failure of the scaffolding system in the intervertebral space.

(7) Accordingly, and for at least the above reasons, those of skill in the art will appreciate bone graft distribution systems that facilitate an improved distribution of graft material throughout the intervertebral space. Such systems are provided herein, the systems configured to (i) effectively distribute bone graft material both from the system, and around the system, to improve the strength

and integrity of a fusion; (ii) reduce or eliminate the problem of failures resulting from a poor bone graft distribution; (iii) have a small maximum dimension in a collapsed state for a low-profile insertion into the annulus in a minimally-invasive manner, whether using only a unilateral approach or a bilateral approach; (iv) laterally expand within the intervertebral space to avoid backout of the system through the annulotomy; (v) vertically expand for distraction of the intervertebral space; (vi) provide an expansion in the intervertebral space without contracting the system in length to maintain a large footprint and an anterior position adjacent to the inner, anterior annulus wall, distributing load over a larger area, anteriorly, against the endplates; (vii) and, incorporate a stabilizer for stabilizing and/or retaining support beams upon expansion of the scaffolding in an intervertebral disc space.

## SUMMARY

(8) The teachings herein are directed to intervertebral scaffolding systems having a stabilizer for stabilizing and/or retaining support beams upon expansion of the scaffolding in an intervertebral disc space. As such, the teachings herein are generally directed to an intervertebral scaffolding system.

(9) The systems provided herein can comprise, for example, a central beam having a central beam axis; a proximal portion and a distal portion; a top surface with a first top-lateral surface and a second top-lateral surface; a bottom surface with a first bottom-lateral surface and a second bottom-lateral surface; a first side surface with a first top-side surface and a first bottom-side surface; and, a second side surface with a second top-side surface and a second bottom-side surface. The systems can also comprise a laterovertically-expanding frame configured for operably contacting the central beam to create an intervertebral scaffolding system in vivo. The frame can have a collapsed state and an expanded state, the expanded state operably contacting with the central beam in the intervertebral space; a proximal portion having an end, a distal portion having an end, and a central frame axis of the expanded state.

(10) In some embodiments, the frame can be constructed to have a first top beam including a proximal portion having an end and a distal portion having an end, the first top beam configured for contacting the first top-lateral surface of the central beam and the first top-side surface of the central beam in the expanded state, a central axis of the first top beam at least substantially on (i) a top plane containing the central axis of the first top beam and a central axis of a second top beam and (ii) a first side plane containing the central axis of the first top beam and a central axis of a first bottom beam; the second top beam including a proximal portion having an end and a distal portion having an end, the second top beam configured for contacting the second top-lateral surface of the central beam and the second top-side surface of the central beam in the expanded state, the central axis of the second top beam at least substantially on (i) the top plane and (ii) a second side plane containing the central axis of the second top beam and a central axis of a second bottom beam; the first bottom beam including a proximal portion having an end and a distal portion having an end, the first bottom beam configured for contacting the first bottom-lateral surface of the central beam and the first bottom-side surface of the central beam in the expanded state, the central axis of the first bottom beam at least substantially on (i) a bottom plane containing the central axis of the first bottom beam and the central axis of the second top beam and (ii) the first side plane; the second bottom beam including a proximal portion having an end and a distal region having an end, the second bottom beam configured for contacting the second bottom-lateral surface of the central beam and the second bottom-side surface of the central beam in the expanded state, the central axis of the second bottom beam being at least substantially on (i) the bottom plane and (ii) a second side plane containing the central axis of the second bottom beam and the central axis of the second top beam.

(11) The frame can also be constructed, for example, to have a plurality of top connector elements configured to expandably connect the first top beam to the second top beam, the expanding consisting of a flexing at least substantially on the top plane; a plurality of bottom connector

elements configured to expandably connect the first bottom beam to the second bottom beam, the expanding consisting of a flexing at least substantially on the bottom plane; a plurality of first side connector elements configured to expandably connect the first top beam to the first bottom beam, the expanding consisting of a flexing at least substantially on the first side plane; and, a plurality of second side connector elements configured to expandably connect the second top beam to the second bottom beam, the expanding consisting of a flexing at least substantially on the second side plane

(12) In some embodiments, the systems include a stabilizer that slidably engages with the distal region of the first top beam, the first bottom beam, the second top beam, the second bottom beam, or a combination thereof. The stabilizer can be configured for retaining the first top beam, the first bottom beam, the second top beam, the second bottom beam, or the combination thereof, from a lateral movement that exceeds the expanded state.

(13) And, in some embodiments, the framing can be configured for engaging with the central beam in vivo to support the framing in the expanded state. Moreover, the connector elements can be struts configured to have a cross-sectional aspect ratio of longitudinal thickness to transverse thickness ranging from 1:2 to 1:8, adapted to maintain structural stiffness in the lateroververtically expanding frame in a direction perpendicular to the central frame axis of the expanded state of the frame.

(14) The stabilizer can be in an X-configuration. In some embodiments, the X-configuration can have a first top leg for slidably-engaging with the first top beam at an angle  $\theta_{\text{sub.1T}}$  with the lateral movement of the first top beam, first bottom leg for slidably engaging with the first bottom beam at an angle  $\theta_{\text{sub.1B}}$  with the lateral movement of the first bottom beam, a second top leg for slidably engaging with the second top beam at an angle  $\theta_{\text{sub.2T}}$  with the lateral movement of the second top beam, and a second bottom leg for slidably engaging with the second bottom beam at an angle  $\theta_{\text{sub.2B}}$  with the lateral movement of the second bottom beam. In some embodiments, each of the angles  $\theta_{\text{sub.1T}}$ ,  $\theta_{\text{sub.1B}}$ ,  $\theta_{\text{sub.2T}}$ ,  $\theta_{\text{sub.2B}}$ , respectively, provide a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from the lateral movement that exceeds the expanded state. In some embodiments, the stabilizer further comprises a point of attachment for releasably attaching a guidewire for guiding the central beam into the lateroververtically expanding frame. And, in some embodiments, the first top leg, the first bottom leg, the second top leg, and the second bottom leg converge to form a hub having a point of attachment for releasably attaching a guidewire for guiding the central beam into the lateroververtically expanding frame.

(15) The stabilizer can be in an H-configuration. The H-configuration can have a first vertical leg, a second vertical leg, and a cross-member that connects the first vertical leg at least substantially parallel to the second vertical leg, the first vertical leg including a retaining surface for engaging with the first top beam and the first bottom beam, the second vertical leg including a retaining surface for engaging with the second top beam and the second bottom beam, and the cross member providing a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from the lateral movement that exceeds the expanded state. In some embodiments, the central beam has a horizontal groove configured complementary to the cross-member of the stabilizer, and the horizontal groove of the central beam slidably connects with the cross-member in the expanded state. In some embodiments, the cross-member further comprises a vertical support member and the central beam has a vertical groove configured complementary to the vertical support member of the stabilizer, and the vertical groove of the central beam slidably connects with the vertical support member in the expanded state. In some embodiments, the stabilizer further comprises a point of attachment for releasably attaching a guidewire adapted for guiding the central beam into the lateroververtically expanding frame. And, in some embodiments, cross-member includes a first pillar and a second pillar that operably connect at a hub that has a point of attachment for releasably attaching a guidewire for guiding the central

beam into the lateroververtically expanding frame.

(16) In some embodiments, the systems are bone graft distribution systems. In these embodiments, the central beam can further comprise a grafting port. Likewise the expanding frame can open bone graft distribution windows on the top, the bottom, the sides, or a combination thereof, upon expansion.

(17) In some embodiments, the frame can be formed monolithically. In these embodiments, each plurality connector elements can be struts; wherein, the top struts are configured monolithically integral to the first top beam and the second top beam; and, the bottom struts are configured monolithically integral to the first bottom beam and the second bottom beam. The top struts and the bottom struts of the lateroververtically-expanding frame can each be configured to open a graft distribution window upon expansion, expanding from the first top beam to the second top beam, the first top beam to the first bottom beam, the second top beam to the second bottom beam, or the first bottom beam to the second bottom beam. Likewise, in some embodiments, the top connector struts are configured monolithically integral to the first top beam and the second top beam; and, the bottom struts are configured monolithically integral to the first bottom beam and the second bottom beam; the first side struts are configured monolithically integral to the first top beam and the first bottom beam; and, the second side struts are configured monolithically integral to the second top beam and the second bottom beam. It should be appreciated that, in such embodiments, the top, bottom, first side, and second side of the lateroververtically-expanding frame can form a monolithically integral frame.

(18) The teachings are also directed to a method of fusing an intervertebral space. The methods can use the scaffolding systems taught herein. For example, the methods can include creating a point of entry into an intervertebral disc, the intervertebral disc having a nucleus pulposus surrounded by an annulus fibrosis; removing the nucleus pulposus from within the intervertebral disc through the point of entry, leaving the intervertebral space for expansion of the scaffolding system of claim 1 within the annulus fibrosis, the intervertebral space having a top vertebral plate and a bottom vertebral plate; inserting the lateroververtically expanding frame in the collapsed state through the point of entry into the intervertebral space; inserting the central beam into the frame to form the scaffolding system; and, adding a grafting material to the intervertebral space.

(19) The step of creating the point of entry can comprise creating a lateral dimension of the point of entry ranging from about 5 mm to about 15 mm, and the amount of lateral expansion can be selected to exceed the lateral dimension of the point of entry. The step of expanding can include expanding the lateroververtically expanding frame laterally to a width that exceeds the width of the point of entry; and, inserting the central beam to expand the lateroververtically expanding frame vertically to support the frame in the expanded state. The step of inserting the central beam into the lateroververtically expanding frame includes engaging a means for preventing the central beam from backing out of the lateroververtically-expanding frame after the expanding.

(20) The teachings are also directed to a kit comprising a scaffolding system taught herein. The systems can include a cannula for inserting the scaffolding system into the intervertebral space; and, a guidewire adapted for guiding the central beam into the lateroververtically expanding frame.

---

## Description

### BRIEF DESCRIPTION OF THE FIGURES

(1) FIGS. 1A-1I illustrate components of the graft distribution system, according to some embodiments.

(2) FIGS. 2A-2F illustrate a method of using a bidirectionally-expandable cage, according to some embodiments.

(3) FIGS. 3A-3D illustrate a bidirectionally-expandable cage for fusing an intervertebral disc space,

according to some embodiments.

(4) FIGS. 4A and 4B illustrate collapsed and expanded views of a bidirectionally-expandable cage having a bone graft window on each wall for fusing an intervertebral disc space, according to some embodiments.

(5) FIGS. 5A-5D illustrate system for fusing an intervertebral disc space, according to some embodiments.

(6) FIG. 6 is a diagram of a method of using a bidirectionally-expandable cage, according to some embodiments.

(7) FIGS. 7A-7F illustrate some additional features of graft distribution systems, according to some embodiments.

(8) FIGS. 8A-8D illustrate components of a graft distribution kit, according to some embodiments.

(9) FIGS. 9A-9C illustrate the expansion of a laterovertically-expandable frame in an intervertebral space, according to some embodiments.

(10) FIGS. 10A-10C illustrate profiles of an expanded graft distribution system to highlight the exit ports and bone graft windows, according to some embodiments.

(11) FIGS. 11A and 11B compare an illustration of the graft distribution in place to a test placement in a cadaver to show relative size, according to some embodiments.

(12) FIGS. 12A-12C show x-rays of a placement in a cadaver, according to some embodiments.

(13) FIGS. 13A-13D show orientations of the first top beam relative to the second top beam, first bottom beam relative to the second bottom beam, first top beam relative to the first bottom beam, and the second top beam relative to the second bottom beam, according to some embodiments.

(14) FIGS. 14A-14D illustrate components of a system having a stabilizer, wherein the stabilizer is in an X-configuration, according to some embodiments.

(15) FIGS. 15A-15D illustrate components of a system having a stabilizer, wherein the stabilizer is in an H-configuration, according to some embodiments.

#### DETAILED DESCRIPTION OF THE INVENTION

(16) The teachings herein are directed to intervertebral scaffolding systems having a stabilizer for stabilizing and/or retaining support beams upon expansion of the scaffolding in an intervertebral disc space. The systems can have, for example, a central beam having a proximal portion having an end, a grafting portion having a top and a bottom, a distal portion having an end, a central beam axis, a graft distribution channel having an entry port at the end of the proximal portion, a top exit port at the top of the grafting portion, and a bottom exit port at the bottom of the grafting portion. These systems can also include a laterovertically-expanding frame having a lumen, a first top beam, a second top beam, a first bottom beam, and a second bottom beam, each having a proximal portion and a distal portion, and each operably connected to each other at their respective proximal portions and distal portions with connector elements to form the laterovertically-expanding frame that is operable for a reversible collapse from an expanded state into a collapsed state. The expanded state, for example, can be configured to have an open graft distribution window that at least substantially closes upon the reversible collapse. In these embodiments, the laterovertically-expanding frame is adapted for receiving an insertion of the central beam to form the graft distribution system.

(17) In some embodiments, the systems can also include a laterovertically-expanding frame having a first top beam, a second top beam, a first bottom beam, and a second bottom beam; wherein, the beams are in an at least substantially parallel arrangement with each other, each having a proximal portion, a grafting portion, and a distal portion, and each operably connected to each other at their respective proximal portions and distal portions to form the laterovertically-expanding frame in a square, cylindrical shape that is operable for a reversible collapse from an expanded state into a collapsed state. The expanded state, for example, can be configured to have an open graft distribution window that at least substantially closes upon the reversible collapse. In these embodiments, the laterovertically-expanding frame is adapted for receiving an insertion of the central beam to form the graft distribution system.

(18) The term “subject” and “patient” can be used interchangeably in some embodiments and refer to an animal such as a mammal including, but not limited to, non-primates such as, for example, a cow, pig, horse, cat, dog; and primates such as, for example, a monkey or a human. As such, the terms “subject” and “patient” can also be applied to non-human biologic applications including, but not limited to, veterinary, companion animals, commercial livestock, and the like. Moreover, terms of degree are used herein to provide relative relationships between the position and/or movements of components of the systems taught herein. For example, the phrase “at least substantially parallel” is used to refer to a position of one component relative to another. An axis that is at least substantially parallel to another axis refers to an orientation that is intended, for all practical purposes to be parallel, but it is understood that this is just a convenient reference and that there can be variations due to stresses internal to the system and imperfections in the devices and systems. Likewise, the phrase “at least substantially on a . . . plane” refers to an orientation or movement that is intended, for all practical purposes to be on or near the plane as a convenient measure of the orientation or movement, but it is understood that this is just a convenient reference and that there can be variations due to stresses internal to the system and imperfections in the devices and systems. Likewise, the phrase “at least substantially coincident” refers to an orientation or movement that is intended, for all practical purposes to be on or near, for example, an axis or a plane as a convenient measure of the orientation or movement, but it is understood that this is just a convenient reference and that there can be variations due to stresses internal to the system and imperfections in the devices and systems.

(19) FIGS. 1A-1I illustrate components of the system, according to some embodiments. As shown in FIG. 1A, the graft distribution systems **100** can have a central beam **101** with a central beam axis **105**, a graft distribution channel with an entry port **135** in fluid communication with a top exit port **140**, and a bottom exit port **141**. The central beam **101** can also have a proximal portion **111** having and end with the entry port **135**, a grafting portion **112** having the top exit port **140** and the bottom exit port **141**, and a distal portion (not shown). The central beam **101** can also be sized to have a transverse cross-section **110** having a maximum dimension ranging from 5 mm to 15 mm for placing the central beam **101** into an intervertebral space through an annular opening having a maximum lateral dimension ranging from 5 mm to 15 mm, the intervertebral space having a top vertebral plate and a bottom vertebral plate. The central beam **101** can also have a top surface **115** with a first top-lateral surface **117** and a second top-lateral surface **119**, a bottom surface **120** with a first bottom-lateral surface **122** and a second bottom-lateral surface **124**, a first side surface **125** with a first top-side surface **127** and a first bottom-side surface **129**, and a second side surface **130** with a second top-side surface **132** and a second bottom-side surface **134**.

(20) In some embodiments, the central beam can have transverse cross-sectional lateral dimension ranging from about 5 mm to about 15 mm. In some embodiments, the vertical dimension of the central beam can range from about 4 mm to about 12 mm, about 5 mm to about 11 mm, about 6 mm to about 10 mm, and about 7 mm to about 9 mm, about 6 mm to about 8 mm, about 6 mm, or any range or amount therein in increments of 1 mm. In some embodiments, the lateral dimension of the central beam can range from about 5 mm to about 15 mm, about 6 mm to about 14 mm, about 7 mm to about 13 mm, about 8 mm to about 12 mm, about 10 mm, or any range or amount therein in increments of 1 mm. In some embodiments, transverse cross-section of the central beam has an area with an effective diameter ranging from about 2 mm to about 20 mm, from about 3 mm to about 18 mm, from about 4 mm to about 16 mm, from about 5 mm to about 14 mm, from about 6 mm to about 12 mm, from about 7 mm to about 10 mm, or any range therein. In some embodiments, the low profile has an area with a diameter of 2 mm, 4 mm, 6 mm, 8 mm, 10 mm, 12 mm, 14 mm, 16 mm, 18 mm, or any range therein, including any increment of 1 mm in any such diameter or range therein. In some embodiments, the width (mm)×height (mm) of the central beam can be 9.0×5.0, 9.0×6.0, 9.0×7.0, 9.0×8.0, 9.0×9.0, and 9.0×10.0, or any deviation in dimension therein in increments of +/-0.1 mm. And, in some embodiments, the central beam can have a

transverse cross-sectional lateral or vertical dimension that ranges from 6.5 mm to 14.0 mm.

(21) As shown in FIGS. 1B and 1C, the system **100** can also comprise a laterovertically-expanding frame **149** configured for operably contacting the central beam **101** to create a graft distribution system **100** in vivo, the frame **149** having a collapsed state **149c** with a transverse cross section **149ct** having a maximum dimension ranging from 5 mm to 15 mm for placing the frame **149** in the intervertebral space through the annular opening for expansion. Likewise, the frame **149** can also have an expanded state **149e** with a transverse cross section **149et** having a maximum dimension ranging from 6.5 mm to 18 mm for retaining the frame **149** in the intervertebral space, the expanded state operably contacting with the central beam **101** in the intervertebral space. The frame **149** can be defined as including a proximal portion **111** having an end, a grafting portion **112**, a distal portion (not shown) having an end, and a central frame axis **113** of the expanded state **149e**.

(22) In some embodiments, the frame can have transverse cross-sectional lateral dimension in the collapsed state ranging from about 5 mm to about 15 mm. In some embodiments, the vertical dimension of the frame in the collapsed state can range from about 4 mm to about 12 mm, about 5 mm to about 11 mm, about 6 mm to about 10 mm, and about 7 mm to about 9 mm, about 6 mm to about 8 mm, about 6 mm, or any range or amount therein in increments of 1 mm. In some embodiments, the lateral dimension of the frame in the collapsed state can range from about 5 mm to about 15 mm, about 6 mm to about 14 mm, about 7 mm to about 13 mm, about 8 mm to about 12 mm, about 10 mm, or any range or amount therein in increments of 1 mm. In some embodiments, transverse cross-section of the frame in the collapsed state has an area with an effective diameter ranging from about 2 mm to about 20 mm, from about 3 mm to about 18 mm, from about 4 mm to about 16 mm, from about 5 mm to about 14 mm, from about 6 mm to about 12 mm, from about 7 mm to about 10 mm, or any range therein. In some embodiments, the low profile has an area with a diameter of 2 mm, 4 mm, 6 mm, 8 mm, 10 mm, 12 mm, 14 mm, 16 mm, 18 mm, or any range therein, including any increment of 1 mm in any such diameter or range therein. In some embodiments, the width (mm)×height (mm) of the frame in the collapsed state can be 9.0×5.0, 9.0×6.0, 9.0×7.0, 9.0×8.0, 9.0×9.0, and 9.0×10.0, or any deviation in dimension therein in increments of +/-0.1 mm. In some embodiments, the frame can have a transverse cross-sectional dimension, lateral or vertical in the expanded state ranging from 4.0 mm to 18 mm, from 5.0 mm to 19.0 mm, from 6.0 mm to 17.5 mm, from 7.0 mm to 17.0 mm, from 8.0 mm to 16.5 mm, from 9.0 mm to 16.0 mm, from 9.0 mm to 15.5 mm, from 6.5 mm to 15.5 mm, or any range or amount therein in increments of +/-0.1 mm.

(23) The term “collapsed state” can be used to refer to a configuration of the frame in which the transverse cross-sectional area, or profile, is at least substantially at its minimum, and the term “expanded state” can be used to refer to a configuration of the frame that is expanded at least substantially beyond the collapsed state. In this context, a frame is expanded at least “substantially” beyond the collapsed state when a bone graft window of the frame has opened from the closed configuration by at least a 20% increase area of the bone graft window from the collapsed state. In some embodiments, the frame is expanded at least “substantially” beyond the collapsed state when a bone graft window of the frame has opened by at least a 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%, 60%, 70%, 80%, 90%, 100%, 150%, 200%, 250%, 300%, or more when compared to the bone graft window from the collapsed state. In some embodiments, the frame is expanded at least “substantially” beyond the collapsed state when a bone graft window of the frame has opened by at least 2×, 3×, 5×, 10×, 15×, 20×, or more when compared to the bone graft window from the collapsed state.

(24) In some embodiments, the laterovertically expandable frames are created in an expanded state. And the expanded state can include a state that is at least 30%, at least 40%, at least 50%, at least 60%, at least 70%, at least 80%, at least 90%, or at least 95% of the full expansion. The term “full expansion” can be used to refer to an extent of expansion upon which a connector element begins to fatigue, fail, or crack; or, in some embodiments, strain beyond 10%, 20%, or 30%.

(25) The frame **149** can be configured to have a first top beam **150** including a proximal portion **111** having an end, a grafting portion **112**, and a distal portion (not shown) having an end, the first top beam **150** configured for contacting the first top-lateral surface **117** of the central beam and the first top-side surface **127** of the central beam **101** in the expanded state **149e**, the central axis of the first top beam at least substantially on (i) a top plane containing the central axis of the first top beam and the central axis of a second top beam and (ii) a first side plane containing the central axis of the first top beam and the central axis of a first bottom beam. Likewise the frame **149** can be configured to have a second top beam **160** including a proximal portion **111** having an end, a grafting portion **112** having an end, and a distal portion (not shown) having an end, the second top beam **160** configured for contacting the second top-lateral surface **119** of the central beam **101** and the second top-side surface **132** of the central beam **101** in the expanded state **149e**, the central axis of the second top beam at least substantially on (i) the top plane and (ii) a second side plane containing the central axis of the second top beam and the central axis of a second bottom beam. Likewise the frame **149** can be configured to have a first bottom beam **170** including a proximal portion **111** having an end, a grafting portion **112**, and a distal portion (not shown) having an end, the first bottom beam **170** configured for contacting the first bottom-lateral surface **122** of the central beam **101** and the first bottom-side surface **129** of the central beam **101** in the expanded state **149e**, the central axis of the first bottom beam at least substantially on (i) a bottom plane containing the central axis of the first bottom beam and the central axis of a second top beam and (ii) the first side plane. Likewise the frame **149** can be configured to have a second bottom beam **180** including a proximal portion **111** having an end, a grafting portion **112** having an end, and a distal region (not shown) having an end, the second bottom beam **160** configured for contacting the second bottom-lateral surface **124** of the central beam **101** and the second bottom-side surface **134** of the central beam **101** in the expanded state **149e**, the central axis of the second bottom beam being at least substantially on (i) the bottom plane and (ii) a second side plane containing the central axis of the second bottom beam and the second top beam.

(26) In some embodiments, the central axis of the first top beam **150** can be at least substantially parallel to the central beam axis **105**. Likewise the frame **149** can be configured to have a second top beam **160** including a proximal portion **111** having an end, a grafting portion **112** having an end, and a distal portion (not shown) having an end, the second top beam **160** configured for contacting the second top-lateral surface **119** of the central beam **101** and the second top-side surface **132** of the central beam **101** in the expanded state **149e**, the central axis of the second top beam **160** being at least substantially parallel to the central beam axis **105**. Likewise the frame **149** can be configured to have a first bottom beam **170** including a proximal portion **111** having an end, a grafting portion **112**, and a distal portion (not shown) having an end, the first bottom beam **170** configured for contacting the first bottom-lateral surface **122** of the central beam **101** and the first bottom-side surface **129** of the central beam **101** in the expanded state **149e**, the central axis of the first bottom beam **170** being at least substantially parallel to the central beam axis **105**. Likewise the frame **149** can be configured to have a second bottom beam **180** including a proximal portion **111** having an end, a grafting portion **112** having an end, and a distal region (not shown) having an end, the second bottom beam **160** configured for contacting the second bottom-lateral surface **124** of the central beam **101** and the second bottom-side surface **134** of the central beam **101** in the expanded state **149e**, the central axis of the second bottom beam **180** being at least substantially parallel to the central beam axis **105**.

(27) As shown in FIG. 1D, the systems provided herein have the layered effect from the frame on the central beam that provides an additive dimension, both laterally and vertically. The added dimension allows for a low profile entry of the system into the intervertebral disc space, a wide lateral profile after expansion in vivo to avoid backout, as well as a sleeve for safe insertion of the central beam between the top endplate and bottom endplate in the intervertebral space. In some embodiments, the first top beam, second top beam, first bottom beam, and second bottom beam can

each have a transverse cross-sectional wall thickness adding to the respective central beam dimension, the thickness ranging from about 0.5 mm to about 5.0 mm, from about 0.75 mm to about 4.75 mm, from about 1.0 mm to about 4.5 mm, from about 1.25 mm to about 4.25 mm, from about 1.5 mm to about 4.0 mm, from about 1.75 mm to about 3.75 mm, from about 2.0 mm to about 3.5 mm, from about 2.25 mm to about 3.25 mm, or any range therein in increments of 0.05 mm. In some embodiments, the first top beam, second top beam, first bottom beam, and second bottom beam can each have a transverse cross-sectional wall thickness adding to the respective central beam dimension, the thickness ranging from about 1.5 mm to about 2.5 mm, including 1.5, 1.75, 2.0, 2.25, 2.5, or an amount therein in increments of 0.05 mm.

(28) The beams of the laterovertically-expanding frame **149** can be operably connected through connector elements. As such, the frame **149** can include a plurality of proximal top connector elements **191** configured to expandably connect the proximal portion **111** of the first top beam **150** to the proximal portion **111** of the second top beam **160**, the expanding consisting of a flexing at least substantially on a top plane containing the central axis of the first top beam **150** and the central axis of the second top beam **160**. Likewise the frame **149** can be configured to have a plurality of distal top connector elements (not shown) configured to expandably connect the distal portion of the first top beam **150** to the distal portion of the second top beam **160**, the expanding consisting of a flexing at least substantially on the top plane.

(29) Likewise the frame **149** can be configured to have a plurality of proximal bottom connector elements **193** configured to expandably connect the proximal portion **111** of the first bottom beam **170** to the proximal portion **111** of the second bottom beam **180**, the expanding consisting of a flexing at least substantially on a bottom plane containing the central axis of the first bottom beam **170** and the central axis of the second bottom beam **180**. Likewise the frame **149** can be configured to have a plurality of distal bottom connector elements (not shown) configured to expandably connect the distal portion of the first bottom beam **170** to the distal portion of the second bottom beam **180**, the expanding consisting of a flexing at least substantially on the bottom plane.

(30) Likewise the frame **149** can be configured to have a plurality of proximal first side connector elements **195** configured to expandably connect the proximal portion **111** of the first top beam **150** to the proximal portion **111** of the first bottom beam **170**, the expanding consisting of a flexing at least substantially on a first side plane containing the central axis of the first top beam **150** and the central axis of the first bottom beam **170**; a plurality of distal first side connector elements (not shown) configured to expandably connect the distal portion of the first top beam **150** to the distal portion of the first bottom beam **170**, the expanding consisting of a flexing at least substantially on the first side plane. Likewise the frame **149** can be configured to have a plurality of proximal second side connector elements **197** configured to expandably connect the proximal portion **111** of the second top beam **160** to the proximal portion **111** of the second bottom beam **180**, the expanding consisting of a flexing at least substantially on a second side plane containing the central axis of the second top beam **160** and the central axis of the second bottom beam **180**; a plurality of distal second side connector elements (not shown) configured to expandably connect the distal portion of the second top beam **160** to the distal portion of the second bottom beam **180**, the expanding consisting of a flexing at least substantially on the second side plane.

(31) In some embodiments, each plurality of proximal connector elements can be configured as proximal struts in an at least substantially parallel alignment in the expanded state and the collapsed state; and, each plurality distal connector elements are distal struts can be configured in an at least substantially parallel alignment in the expanded state and the collapsed state. As such, the proximal top struts can be configured monolithically integral to the first top beam and the second top beam and adapted to flex toward the distal top struts during collapse; and, the distal top struts can be configured monolithically integral to the first top beam and the second top beam and adapted to flex toward the proximal top struts during collapse. Likewise, the proximal bottom struts can be configured monolithically integral to the first bottom beam and the second bottom beam and

adapted to flex toward the distal bottom struts during collapse; and, the distal bottom struts can be configured monolithically integral to the first bottom beam and the second bottom beam and adapted to flex toward the proximal bottom struts during collapse. Likewise, the proximal first side struts can be configured monolithically integral to the first top beam and the first bottom beam and adapted to flex toward the distal first side struts during collapse; and, the distal first side struts can be configured monolithically integral to the first top beam and the first bottom beam and adapted to flex toward the proximal first side struts during collapse. Likewise, the proximal second side struts can be configured monolithically integral to the second top beam and the second bottom beam and adapted to flex toward the distal second side struts during collapse; and, the distal second side struts can be configured monolithically integral to the second top beam and the second bottom beam and adapted to flex toward the proximal second side struts during collapse.

(32) As shown in FIG. 1D, the frame **149** can be configured for slidably engaging with the central beam **101** in vivo following placement of the central beam **101** in the intervertebral space through the annular opening, the slidably engaging including translating the central beam **101** into the frame **149** from the proximal end **11** of the frame **149** toward the distal end of the frame **149** in vivo; the translating including keeping the central beam axis **105** at least substantially coincident with the central frame axis **113** during the translating to create the graft distribution system **100** in vivo through the annular opening. The system **100** can also be configured to form a top graft-slab depth **199t** between the top surface **115** of the central beam **101** and the top vertebral endplate; and, a bottom graft-slab depth **199b** (not shown) between the bottom surface **120** of the central beam **101** and the bottom vertebral endplate in vivo. And, in some embodiments, the transverse cross-section **110** of the system **100** in vivo is greater than the maximum lateral dimension of the annular opening to avoid back-out.

(33) One of skill will appreciate that the central beam can have any configuration that would be operable with the teachings provided herein. In some embodiments, criteria for a suitable central beam may include a combination of a material and configuration that provides a suitable stiffness. In some embodiments, the central beam can comprise an I-beam. An example of an I-beam configuration and a complementary laterovertically expandable cage are shown in FIGS. 1E and 1F.

(34) One of skill will further appreciate that the central beam can have any one or any combination of graft port configurations that would be operable with the teachings provided herein. In some embodiments, criteria for a suitable graft port configuration may include a combination of port size, number of ports, and placement of ports. In some embodiments, the central beam can comprise a side graft port.

(35) One of skill will further appreciate that the connector elements can vary in design but should meet the constraints as taught herein. In some embodiments, for example each of the connector elements **191**, **193**, **195**, **197** can have a cross-sectional aspect ratio of longitudinal thickness to transverse thickness ranging from 1:2 to 1:8. A section of a connector element is shown in FIG. 1G.

(36) As such, the systems can also include an improved, low-profile, intervertebral disc cage that expands bidirectionally. Consistent with the teachings herein, the cages offer several improvements to the art that include, for example, preventing the cage from backing out of the annulus fibrosis after expansion in an intervertebral disc space. As such, the terms “cage,” “scaffold” and “scaffolding”, for example, can be used interchangeably with “laterovertically expandable frame”, “expandable frame”, or “frame”, in some embodiments. The cages have the ability to at least (i) laterally expand within the intervertebral space to avoid backout of the device through the annulotomy, (ii) vertically expand for distraction of the intervertebral space, (iii) provide additional space within the device in the annulus for the introduction of graft materials; (iv) maintain a large, footprint to distribute load over a larger area against the endplate, for example, by not contracting in length to expand in height and/or width; and, (v) insert into the annulus in a minimally-invasive manner using only a unilateral approach.

(37) FIGS. 2A-2F illustrate a method of using a bidirectionally-expandable cage, according to some embodiments. As shown in FIGS. 2A-2B, an annulus **205** is prepared with an annulotomy serving as a single point of entry **210** and an intervertebral space **215** for insertion of a bidirectionally expandable cage system **250**. As shown in FIGS. 2C-2F, the system **250** has a cage **255** having a proximal end **256**, a distal end **257**, and a lumen **258** that communicates with the intervertebral space **215** through an expandable/collapsible bone graft window **259**; a shim core **260** having a tapered nose **262** at the distal end of the shim core **260**; a releasably attachable rail beam **265**; a pusher **270** that slidably translates over the shim core **260** and the rail beam **265**; a trial shim **275** having a shoulder **277** and slidably translating over the rail beam **265** and shim core **260** into the lumen **258** of the cage **255**, and a permanent shim **280** having a shoulder **282** and slidably translating over the rail beam **265** and shim core **260** into the lumen **258** of the cage **255**.

(38) The procedure for implanting the cage **255** begins in FIG. 2A, including inserting a cannula (not shown) with a bullet-nosed obturator through the single point of entry **210** and inside the intervertebral disc space **215** until contacting the opposing wall of the annulus **205**. The cannula (not shown) depth is used to select the desired length of the cage **255**. The shim core **260** is loaded with bone graft material and the rail beam **265** is releasably attached to the shim core **260**. The cage **255** is loaded onto the rail beam **265** and pushed onto the shim core **260** and into the cannula (not shown) using the pusher **270** until the distal end **257** of the cage **255** contacts the back of the tapered nose **262** of the shim core **260** as shown in FIG. 2A. The assembly of the shim core **260** and the cage **255** are inserted into the intervertebral space **215**, and the cannula (not shown) is removed as shown in FIG. 2B. The lumen **258** of the cage **255** is loaded with bone graft material, and the trial shim **275** is slidably translated over the rail beam **265** and the shim core **260** into the lumen **258** of the cage **255** as shown in FIG. 2C. A variety of sizes of the trial shim **275** can be tested until the largest trial shim **275** that will fit is found, or until the trial shim having the desired vertical and lateral dimensions for expansion is used, in order to lateroververtically expand the cage **255** as desired. The trial shim **275** is then removed, and the lumen **258** of the cage **255** is again filled with bone graft material with the shim core **260** remaining in place as shown in FIG. 2D. The permanent shim **280** is then slidably translated along the rail beam **265** and the shim core **260** into the intervertebral space **215** using the pusher **270** until the distal end **257** of the cage **255** contacts the back of the tapered nose **262** of the shim core **260** to maintain the desired laterovertical expansion of the cage **255** as shown in FIG. 2E. The rail beam **265** is then disconnected from the shim core **260** as shown in FIG. 2F.

(39) It should be appreciated that the annulotomy can have nearly any dimension considered desirable to one of skill in the art. The annulotomy can have a vertical dimension, for example, that is the distance between a top vertebral plate and a bottom vertebral plate, the top vertebral plate and the bottom vertebral plate defining the upper and lower borders of the intervertebral disc space. In some embodiments, the vertical dimension can range from about 4 mm to about 12 mm, about 5 mm to about 11 mm, about 6 mm to about 10 mm, and about 7 mm to about 9 mm, about 6 mm to about 8 mm, about 6 mm, or any range or amount therein in increments of 1 mm. In some embodiments, the lateral dimension of the single point of entry can range from about 5 mm to about 15 mm, about 6 mm to about 14 mm, about 7 mm to about 13 mm, about 8 mm to about 12 mm, about 10 mm, or any range or amount therein in increments of 1 mm. In some embodiments, the single point of entry has an area with a diameter ranging from about 2 mm to about 20 mm, from about 3 mm to about 18 mm, from about 4 mm to about 16 mm, from about 5 mm to about 14 mm, from about 6 mm to about 12 mm, from about 7 mm to about 10 mm, or any range therein. In some embodiments, the low profile has an area with a diameter of 2 mm, 4 mm, 6 mm, 8 mm, 10 mm, 12 mm, 14 mm, 16 mm, 18 mm, or any range therein, including any increment of 1 mm in any such diameter or range therein. The low profile dimensions of the cages taught herein are designed to fit within these dimensions.

(40) One of skill will also appreciate that there are several methods and devices that could be used

to expand the cage. In some embodiments, the expanding includes using a means for (i) lateroververtically expanding the cage and (ii) creating a convex surface that at least substantially complements the concavity of a surface of a vertebral endplate that contacts the pair of top beams or the pair of bottom beams.

(41) One of skill will also appreciate a method that distracts the intervertebral space and laterally expands the cage to avoid back-out. As such, in some embodiments, the expanding includes introducing a lateroververtical expansion member into the intervertebral space through the single point of entry and into the cage, the lateroververtical expansion member configured to provide a vertical force through the cage and into the top vertical endplate and bottom vertical endplate to distract the intervertebral space; and, a lateral force on the first side wall and the second side wall to expand the cage to a width that is greater than the lateral dimension of the single point of entry to prevent the bidirectionally-expandable cage from backing out of the annulus fibrosis after the expanding.

(42) One of skill will also appreciate having a method for passing bone grafting material into the intervertebral space. As such, the lateroververtical expansion member can include a port for introducing the grafting material into the intervertebral space. The methods and systems provided herein include the use of bone graft materials known to one of skill. Materials which may be placed or injected into the intervertebral space include solid or semi-solid grafting materials, bone from removed from patient's facet, an iliac crest harvest from the patient, and bone graft extenders such as hydroxyapatite, demineralized bone matrix, and bone morphogenic protein. Examples of solid or semi-solid grafting material components include solid fibrous collagen or other suitable hard hydrophilic biocompatible material. Some materials may also include swelling for further vertical expansion of the intervertebral disc space.

(43) One of skill will also appreciate having a method for retaining the lateroververtical expansion member in the cage. As such, the introducing can include engaging a ratchet mechanism comprising a protuberance on the lateroververtical expansion member that engages with a strut of the cage to prevent the cage from backing out of the annulus fibrosis after the expanding. The ratchet mechanism can be, for example, similar to a zip-tie ratchet mechanism having a gear component and a pawl component. In some embodiments, the cage has the gear component, for example, including the struts; and, the lateroververtical expansion member is a shim device having the pawl component, for example, a projection that can angle toward the proximal end of the expansion member or away from the direction of insertion of the shim device. In some embodiments, the cage has the pawl component, for example, including the struts; and, the lateroververtical expansion member is a shim device having the gear component, for example, a series of projections. In some embodiments, a projection can angle from about 5° to about 75° toward the proximal end of the expansion member or away from the direction of insertion of the shim device.

(44) One of skill will also appreciate having a method of designing the shape of the cage upon expansion. As such, in some embodiments, the expanding includes selecting a shim configured to create a convex surface on the top surface of the top wall to at least substantially complement the concavity of the respective top vertebral plate, and/or the bottom surface of the bottom wall to at least substantially complement the concavity of the respective bottom vertebral plate. In some embodiments, the expanding includes selecting a shim configured to vertically expand the distal end of the cage more than the proximal end of the cage. And, in some embodiments, the expanding includes selecting a shim configured to laterally expand the distal end of the cage more than the proximal end of the cage.

(45) FIGS. 3A-3D illustrate collapsed and expanded views of a bidirectionally-expandable cage for fusing an intervertebral disc space, according to some embodiments. FIGS. 3A and 3C show an expanded configuration, and FIGS. 3B and 3D show a collapsed configuration. The cage **300** can comprise at least 4 walls **302,304,306,308** that form a cylinder having a long axis **309**, the at least 4 walls **302,304,306,308** including a top wall **302** forming a top plane and having a top surface with protuberances (not shown) adapted to contact the top vertebral plate (not shown); a bottom wall

**304** forming a bottom plane and having a bottom surface with protuberances (not shown) adapted to contact the bottom vertebral plate (not shown); a first side wall **306** forming a first side wall plane; and, a second side wall **308** forming a second side wall plane. In these embodiments, each of the walls **302,304,306,308** can have at least 2 longitudinal beams, such that a rectangular cylinder can have a total of 4 longitudinal beams **312,314,316,318**; and, a plurality of struts **333** that (i) stack in the collapsed state of the cage **300**, as shown in FIGS. 3B and 3D, to minimize void space in their respective wall for a low profile entry of the cage **300** both vertically and laterally into a single point of entry (not shown) into an intervertebral disc space (not shown) and (ii) deflect upon expansion to separate the at least 2 longitudinal beams of the total of 4 longitudinal beams **312,314,316,318** in the rectangular cylinder in their respective wall **302,304,306,308**. In addition, the cage **300** can be configured to expand laterally in the intervertebral space (not shown) to a size greater than a lateral dimension of the single point of entry (not shown) to prevent the bidirectionally-expandable cage **300** from backing out of the annulus fibrosis (not shown) after the expanding shown in FIGS. 3A and 3C.

(46) It should be appreciated that the collapsed configuration includes the design of a low profile entry through the annulus fibrosis to allow for a minimally-invasive procedure. In order to facilitate the use of a minimally-invasive procedure, the low profile entry of the collapsed configuration should be a substantially small area of entry having a diameter ranging, for example, from about 5 mm to about 12 mm for the single point of entry through the annulus fibrosis. In some embodiments, the low profile has an area with a diameter ranging from about 2 mm to about 20 mm, from about 3 mm to about 18 mm, from about 4 mm to about 16 mm, from about 5 mm to about 14 mm, from about 6 mm to about 12 mm, from about 7 mm to about 10 mm, or any range therein. In some embodiments, the low profile has an area with a diameter of 2 mm, 4 mm, 6 mm, 8 mm, 10 mm, 12 mm, 14 mm, 16 mm, 18 mm, or any range therein, including any increment of 1 mm in any such diameter or range therein.

(47) One of skill will appreciate that a variety of strut configurations may be contemplated to minimize void space for the low profile entry of the cage into the intervertebral space. In some embodiments, each wall of the cage has a series of v-shaped struts **333** that (i) stack in a closed-complementary configuration **344** in the collapsed state to minimize void space in their respective wall for the low profile entry of the cage both vertically and laterally into the intervertebral space, and (ii) deflect upon expansion in a plane that is at least substantially parallel to the plane of their respective wall to an open-complementary configuration **355** to separate the at least 2 longitudinal beams of the total of 4 longitudinal beams **312,314,316,318** in the rectangular cylinder in their respective wall and open a bone graft window **366** to pass a bone graft material into the intervertebral space in the expanded configuration. In some embodiments, the cage **300** is configured to accommodate the lateral dimension of the single point of entry ranging from about 5 mm to about 15 mm.

(48) The v-shaped struts can be “V” shaped slots projected through each of the cage walls starting at a distance of 2 mm (0.5-4) from each corner of the cage to effectively render the “V” shaped struts in the mid region of the wall faces, in which the struts can be fabricated as continuous with L shaped beams on the corners. The slots can be cut such that they are projected perpendicular to the faces or angled distally from the outside of the cage to the inside of the cage. The distally angled projection can facilitate insertion of the shims taught herein. And, the proximal faces of the corners of the beams can also have inward, distally angled chamfers to facilitate insertion of the shims taught herein. The struts can be uniform in thickness in the proximal-distal direction. In some embodiments, the struts range from about 0.2 mm to about 1.0 mm, from about 0.3 mm to about 0.9 mm, from about 0.4 mm to about 0.8 mm, from about 0.5 mm to about 0.7 mm in thickness, or any range therein in increments of about 0.1 mm. The vertex of the “V” strut can trace along the center axis of the each of the side faces and can be radiused to dimension of 0.031” (0.005-0.062”), in some embodiments, to prevent stress cracking. Moreover, the shape of the strut or the slot

projections can also be C, U, or W, in some embodiments. The struts can be 4 times thicker in the direction perpendicular to the long axis of the cage than in the direction of the long axis of the cage. In some embodiments, this thickness ratio can range from about 2× to about 8×, from about 3× to about 7×, from about 4× to about 6×, about 5×, or any range therein in increments of 1×. This thickness can help maintain a high structural stiffness and strength in the direction perpendicular to the proximal-distal axis so that the transverse cross section (perpendicular to the proximal-distal axis) shape is maintained during and after insertion of the cage into the intervertebral disc space.

(49) In some embodiments, the angle of each strut can range from about 140°-170° as measured at the vertex in the non-stressed state. In these embodiments, the angle facilitates flexion of the legs of each strut towards each other upon moderate inward pressure to collapse the cage for insertion into the disc space. Furthermore the angled strut lies in a plane at least substantially parallel to the plane of it's respective wall, and in some embodiments to the long axis of the cage, so that the flexion does not alter the side wall thickness. This helps to maintain the low profile for insertion while maximizing the lumen size. This geometry combined with the solid beams on the corners helps ensure that the implant has a minimal change in length, less than 15% reduction in length as measured along the long axis, when expanded more than 20% vertically and/or horizontally. As such, the top and bottom of the cage that support the vertebra remain at least substantially constant in length regardless of expansion.

(50) In some embodiments, the cage **300** has v-shaped struts **333** and a bone graft window **366** that (i) complements the v-shaped struts **333** in the collapsed configuration and (ii) opens upon expansion to pass a bone graft material into the intervertebral space in the open-complementary configuration **355**, which can also be referred to as an expanded configuration. And, in some embodiments, the cage **300** has a proximal region **311**, a proximal end **322**, a distal region **388**, a distal end **399**, and at least one of the at least 4 walls **302,304,306,308** having a first series of v-shaped struts **333** that are configured to stack in a closed-complementary configuration **344** in the collapsed state to minimize void space for the low profile entry of the cage **300** into the intervertebral space; and, deflect upon expansion to an open-complementary configuration **355** to separate the at least 2 longitudinal beams of the total of 4 longitudinal beams **312,314,316,318** in the rectangular cylinder in their respective wall and open a bone graft window **366** adapted to pass a bone graft material into the intervertebral space in the expanded configuration; wherein, the first series of v-shaped struts **333F** is located in the proximal region of the cage, the vertices of the first series of v-shaped struts **333F** pointing away from the proximal end **322** of the cage **300** and toward the distal end **399** of the cage **300**. In some embodiments, the cage **300** can further comprise a second series of v-shaped struts **333S** that stack in a closed-complementary configuration **344** in the collapsed state to minimize void space for the low profile entry of the cage **300** into the intervertebral space; and, deflect upon expansion to an open-complementary configuration **355** to separate the at least 2 longitudinal beams of the total of 4 longitudinal beams **312,314,316,318** in the rectangular cylinder in their respective wall and open a bone graft window **366** adapted to pass a bone graft material into the intervertebral space in the expanded configuration; wherein, the second series of v-shaped struts **333S** is located in the distal region **388** of the cage **300**, the vertices of the second series of v-shaped struts **333S** pointing away from the distal end **399** of the cage **300** and toward the proximal end **322** of the cage **300**. In such embodiments, the strut configuration can result in the expansion of the first series of v-shaped struts **333F** and the second series of v-shaped struts **333S** creating a bone graft window **366** that opens to the bow-tie configuration shown in FIGS. 3A and 3C.

(51) One of skill will also appreciate that the cage design provides flexibility in the relative amounts of lateral expansion and vertical expansion, as well as the relative amounts of expansion proximally and distally across the cage in either the lateral or vertical expansions. As such, in some embodiments, the cage is configured such that the ratio of the amount of lateral expansion to the amount of vertical expansion is variable. And, in some embodiments, the cage is configured such

that the ratio of the amount of proximal expansion to the amount of distal expansion is variable for lateral expansion or vertical expansion.

(52) FIGS. 4A and 4B illustrate collapsed and expanded views of a bidirectionally-expandable cage having a bone graft window on each wall for fusing an intervertebral disc space, according to some embodiments. FIG. 4A shows the cage 400 in the collapsed configuration for a low-profile entry 405 into a single point of entry into an intervertebral disc space, and FIG. 4B shows the cage 400 in the expanded configuration to distract the intervertebral disc space and avoid back-out of the cage through the single point of entry after the expansion. As shown, each wall contains a bone graft window 466 for passing bone graft material into the intervertebral disc space.

(53) FIGS. 5A-5D illustrate system for fusing an intervertebral disc space, according to some embodiments. As shown, the system 550 has a cage 555 having an expandable/collapsible bone graft window 566; a shim core 560 having a tapered nose 562 at the distal end of the shim core 560 and a bone graft window 566; a releasably attachable rail beam 565; a pusher (not shown) that slidably translates over the shim core 560 and the rail beam 565; a trial shim 575 having a shoulder 577 and slidably translating over the rail beam 565 and shim core 560 into the cage 555, and a permanent shim 580 having a shoulder 582 and slidably translating over the rail beam 565 and shim core 560 into the cage 555. The system can comprise a bidirectionally-expandable cage having at least 4 walls that form a cylinder having a long axis. The at least 4 walls can include, for example, a top wall forming a top plane and having a top surface with protuberances adapted to contact the top vertebral plate; a bottom wall forming a bottom plane and having a bottom surface with protuberances adapted to contact the bottom vertebral plate; and, a first side wall forming a first side wall plane, and a second side wall forming a second side wall plane. Each of the walls can have at least 2 longitudinal beams; and, a plurality of struts that (i) stack in the collapsed state to minimize void space in their respective wall for a low profile entry of the cage both vertically and laterally into a single point of entry into an intervertebral disc; and, (ii) deflect upon expansion to separate the at least 2 longitudinal beams in their respective wall. In some embodiments, the cage can be configured to expand laterally in the intervertebral space to a size greater than a lateral dimension of the single point of entry to prevent the bidirectionally-expandable cage from backing out of the annulus fibrosis after the expanding. Moreover, the system can include a laterovertical expansion member configured to induce the laterally expanding and the vertically expanding of the cage; and, a core configured to guide the laterovertical expansion member into the cage to induce the laterally expanding and the vertically expanding of the cage.

(54) One of skill will appreciate that the laterovertical expansion member can also be configured to slidably engage with the core to translationally enter the cage in along the long axis of the cage. In some embodiments, the lateral expansion can occur concurrent with the vertical expansion and, in some embodiments, the lateral expansion can occur prior to the vertical expansion, for example, to reduce frictional stress on the cage during the lateral expansion. A two stage shim, for example, can be used. A first stage shim can be inserted to expand the cage laterally before inserting a second stage shim to expand the cage vertically. In some embodiments, the second stage shim can slidably translate along the first stage shim. The shim can be made of any material considered desirable to one of skill, for example, a metal or a polymer. In some embodiments, the shim can comprise a non-resorbable polymer material, an inorganic material, a metal, an alloy, or bone.

(55) One of skill will appreciate that a system can include all or any combination of the above. As such, the teachings also include system for fusing an intervertebral disc space, the system comprising a bidirectionally-expandable cage having a proximal region, a proximal end, a distal region, a distal end, and at least 4 walls, the cage fabricated as a continuous single piece. In these embodiments, the at least 4 walls form a cylinder having a long axis and include a top wall forming a top plane and having a top surface with protuberances adapted to contact the top vertebral plate; a bottom wall forming a bottom plane and having a bottom surface with protuberances adapted to contact the bottom vertebral plate; and, a first side wall forming a first side wall plane, and a

second side wall forming a second side wall plane. Each of the walls can have at least 2 longitudinal beams and a plurality of struts.

(56) At least one of the walls can have a first series of v-shaped struts that are configured to stack in a closed-complementary configuration in the collapsed state to minimize void space for a low profile entry of the cage through a single point of entry into an intervertebral disc space; and, deflect upon expansion to an open-complementary configuration to separate the at least 2 longitudinal beams in their respective wall and open a bone graft window adapted to pass a bone graft material into the intervertebral space in the expanded configuration. The first series of v-shaped struts can be located in the proximal region of the cage, the vertices of the first series of v-shaped struts pointing away from the proximal end of the cage and toward the distal end of the cage; and, the cage can be configured to expand laterally in the intervertebral space to a size greater than a lateral dimension of the single point of entry to prevent the bidirectionally-expandable cage from backing out of the annulus fibrosis after the expanding. A laterovertical expansion member can be configured to induce the laterally expanding and the vertically expanding of the cage; and, a core can be configured to guide the laterovertical expansion member into the proximal end of the cage, and along the long axis of the cage, to expand the cage laterally and vertically. Moreover, the laterovertical expansion member can slidably engage with the core to translationally enter the cage along the long axis of the cage.

(57) One of skill will appreciate that the systems and system components can be manufactured using any method known to one of skill in the manufacture of such intricate metal and/or polymeric components. For example, the cage can be fabricated in a partially expanded state or a fully expanded state. Moreover, the cage can be manufactured to have no internal stress or strain in the partially or fully expanded state when no external loading is applied.

(58) The system components can comprise any suitable material, or any combination of materials, known to one of skill. For example, all components can be metal, all components can be plastic, or the components can be a combination of metal and plastic. One of skill will appreciate that the cages can have performance characteristics that are near that of a bone structure, in some embodiments, such that the scaffoldings are not too stiff or hard, resulting in a localized loading issue in which the scaffolding puts too much pressure on native bone tissue, and likewise such that the scaffoldings are too flexible or soft, resulting in a localized loading issue in which the bone tissue puts too much pressure on the scaffolding. A radio-opaque material can be employed to facilitate identifying the location and position of the scaffolding in the spinal disc space. Examples of such materials can include, but are not limited to, platinum, tungsten, iridium, gold, or bismuth.

(59) One of skill can select materials on the basis of desired material performance characteristics. For example, one of skill will look to performance characteristics that can include static compression loading, dynamic compression loading, static torsion loading, dynamic torsion loading, static shear testing, dynamic shear testing, expulsion testing, and subsidence testing. The parameters for upper and lower limits of performance for these characteristics can fall within the range of existing such spinal devices that bear the same or similar environmental conditions during use. For example, a desired static compression loading can be approximately 5000N. A desired dynamic compression loading can have an asymptotic load level of  $\geq 3000\text{N}$  at  $5 \times 10^6$  cycles or  $\geq 1500\text{N}$  at  $10 \times 10^6$  cycles. The desired load level can range, for example, from about  $1.0\times$  to about  $2.0\times$ , from about  $1.25\times$  to about  $1.75\times$ , or any range therein in increments of  $0.1\times$ , the vertebral body compression strength. Examples of standard procedures used to test such performance characteristics include ASTM F2077 and ASTM F2624.

(60) Examples of suitable materials can include non-reinforced polymers, carbon-reinforced polymer composites, PEEK (polyether ketone) and PEEK composites, polyetherimide (ULTEM), polyimide, polyamide or carbon fiber. Other examples include metals and alloys comprising any one or more components including, but not limited to, shape-memory alloys, nickel, titanium, titanium alloys, cobalt chrome alloys, stainless steel, ceramics and combinations thereof. In some

embodiments, the components are all titanium or titanium alloy; all PEEK; or a combination of titanium or titanium alloy and PEEK. In some embodiments, the cage comprises titanium or titanium alloy, and the shim comprises PEEK. In some embodiments, the scaffolding can comprise a metal frame and cover made of PEEK or ULTEM. Examples of titanium alloys can include alloys of titanium, aluminum, and vanadium, such as Ti.sub.6Al.sub.4V in some embodiments.

(61) In some embodiments, the cage can be fabricated from strong and ductile polymers having a tensile modulus of about 400,000 psi or more, and a tensile strength of about 14,000 psi or more. Such polymers may also have the ability to strain more than 4% to break, and perhaps at least 20% to break in some embodiments. The materials can be stiffened by being filled with glass fibers or carbon fibers in some embodiments.

(62) Bone ingrowth is desirable in many embodiments. As such, the scaffolding can comprise materials that contain holes or slots to allow for such bone ingrowth. Consistently, the scaffoldings can be coated with hydroxyapatite, or other bone conducting surface, for example, bone morphogenic protein, to facilitate bone ingrowth. Moreover, the surfaces of the scaffoldings can be formed as rough surfaces with protuberances, insets, or projections of any type known to one of skill, such as teeth or pyramids, for example, to grip vertebral endplates, avoid migration of the scaffolding, and encourage engagement with bone ingrowth.

(63) The methods and systems provided herein include the use of bone graft materials known to one of skill. Materials which may be placed or injected into the intervertebral space include solid or semi-solid grafting materials, bone from removed from patient's facet, an iliac crest harvest from the patient, and bone graft extenders such as hydroxyapatite, demineralized bone matrix, and bone morphogenic protein. Examples of solid or semi-solid grafting material components include solid fibrous collagen or other suitable hard hydrophilic biocompatible material. Some materials may also include swelling for further vertical expansion of the intervertebral disc space.

(64) The systems taught herein can be provided to the art in the form of kits. A kit can contain, for example, a cage, a vertical expansion member, and a bone graft material. In some embodiments, the kit will contain an instruction for use. The vertical expansion member can be any vertical expansion mechanism or means taught herein. For example, the vertical expansion member can be a shim. In some embodiments, the kit includes a graft-injection shim for temporarily distracting the intervertebral space, the graft-injection shim having a port for receiving and distributing the bone graft material in the intervertebral space. In these embodiments, the graft-injection shim can remain as a permanent shim or be removed and replaced with a permanent shim.

(65) FIG. 6 is a flowchart of a method of using a bidirectionally-expandable cage, according to some embodiments. The methods can include creating **605** a single point of entry into an intervertebral disc, the intervertebral disc having a nucleus pulposus surrounded by an annulus fibrosis, and the single point of entry having a lateral dimension created through the annulus fibrosis. The methods can also include removing **615** the nucleus pulposus from within the intervertebral through the single point of entry, leaving an intervertebral space for expansion of a bidirectionally-expandable cage within the annulus fibrosis, the intervertebral space having a top vertebral plate and a bottom vertebral plate. The methods can also include inserting **625** a bidirectionally-expandable cage through the single point of entry into the intervertebral space. Moreover, the methods can include expanding **635** the cage in the intervertebral space both laterally and vertically, adding **645** a grafting material to the intervertebral space through the single point of entry, and inserting **665** a permanent shim into the cage.

(66) One of skill will appreciate having the ability to control the amounts of vertical expansion and lateral expansion of the cage to accommodate a variety of applications, for example, to accommodate a variety annulotomy dimensions used for the single point of entry. As such, in some embodiments, the expanding **635** includes selecting **655** an amount of lateral expansion independent of an amount of vertical expansion. The lateral expanding of the cage can be selected, for example, to exceed the lateral dimension of the single point of entry through an annulotomy by

a desired amount to avoid, or prevent, the cage from backing out of the intervertebral space after expansion.

(67) As such, methods of fusing an intervertebral space are provided herein using any of the graft distribution systems taught herein. The methods can include creating a single point of entry into an intervertebral disc, the intervertebral disc having a nucleus pulposus surrounded by an annulus fibrosis, and the single point of entry having the maximum lateral dimension created through the annulus fibrosis. The methods can also include removing the nucleus pulposus from within the intervertebral disc through the single point of entry, leaving the intervertebral space for expansion of the graft distribution system within the annulus fibrosis, the intervertebral space having the top vertebral plate and the bottom vertebral plate. The methods can also include inserting the laterover vertically expanding frame in the collapsed state through the single point of entry into the intervertebral space; and, inserting the central beam into the frame to form the graft distribution system. Moreover, the methods can also include adding a grafting material to the intervertebral space through the entry port.

(68) FIGS. 7A-7F illustrate some additional features of graft distribution systems, according to some embodiments. The graft distribution systems **700** provided herein have at least a top exit port **740** and a bottom exit port **741** in the grafting portion of the central beam **701**, but they can also contain side ports **742,743**, such that there are at least 4 graft distribution ports in some embodiments. In some embodiments, the central beam **701** further comprises a first side graft port **742** and a second side graft port **743**, in addition to a locking clip **702** at the proximal end of the central beam. In some embodiments, the laterover vertically-expanding frame **749** can be a monolithically integral frame, optionally having a “bullet nose” **703** at the distal end of the frame for safe position of the cage against the anterior inner annulus in vivo, and adapted to open a graft distribution window **788** on at least the top and bottom sides, as well as the first side and second side in some embodiments containing side ports, upon expansion of the connector elements to facilitate graft distribution within the intervertebral space.

(69) The distal end of the frame **749** can be configured to have a laterover vertically operable connection with a guide plate **707** that restricts the first top beam, the first bottom beam, the second top beam, and the second bottom beam to laterover vertical movement relative to the guide plate when converting the frame from the collapsed state to the expanded state in vivo. And, in some embodiments, the laterover vertically-expandable frame has a lumen, and the guide plate has a luminal side with a connector **708** for reversibly receiving a guide wire for inserting the laterover vertically-expandable frame into the intervertebral space. In some embodiments, the frame has a chamfer inside the proximal end of the frame beams to facilitate insertion of central beam. And, in many embodiments, the frames have means for creating friction between the vertebral endplates and the frame, such as protuberances, for example cleat-type structures **704**, to further avoid back-out.

(70) As can be seen in at least FIG. 7, the bone graft distribution systems provided herein include bone graft windows defined by the connector elements, the bone graft windows opening upon expansion of the laterover vertically expanding frame. In some embodiments, the method further comprises opening a bone graft window, wherein the connector elements include v-shaped struts that (i) stack either proximally or distally in a closed-complementary configuration in the collapsed state to minimize void space for a low profile entry of the system both vertically and laterally into the intervertebral space, and (ii) deflect upon expansion to open the bone graft window.

(71) It should be appreciated that the bone graft distribution systems provided herein also allow for independent expansion laterally and vertically by expanding in steps. In some embodiments, the expanding includes selecting an amount of lateral expansion independent of an amount of vertical expansion. And, in some embodiments, the lateral expansion exceeds the width of the annular opening that is the single point of entry into the intervertebral space. For example, the lateral dimension of the single point of entry can range from about 5 mm to about 15 mm in some embodiments. As such, in some embodiments, the expanding includes expanding the

laterovertically expanding frame laterally to a width that exceeds the width of the single point of entry; and, inserting the central beam to expand the laterovertically expanding frame vertically to create the graft distribution system.

(72) The bone graft distribution systems provided herein also have additional means for retaining the central beam in the laterovertically expanding frame. In some embodiments, the inserting of the central beam into the laterovertically expanding frame includes engaging a ratchet mechanism comprising a protuberance on the central beam that engages with the laterovertically-expanding frame to prevent the central beam from backing out of the laterovertically-expanding frame after the expanding.

(73) Moreover, the bone graft distribution systems provided herein can be in the form of a kit. The kits can include, for example, a graft distribution system taught herein, a cannula for inserting the graft distribution system into the intervertebral space, a guidewire adapted for guiding the central beam into the laterovertically expanding frame, and an expansion handle for inserting the central beam into the laterovertically expanding frame to form the graft distribution system.

(74) FIGS. 8A-8D illustrate components of a kit, according to some embodiments. FIGS. 8A and 8B illustrate a 4-sided funnel cannula **805** as taught herein having a shaft **810** forming a channel **815**, a funnel **820** for guiding a laterovertically expandable frame into an annulus in a low-profile configuration, the cannula shown with an obturator **825** in the channel **815** of the cannula **805**, the cannula **805** inserted posterolaterally through an annulotomy **877** in the annulus **888**, into an intervertebral space **899**, with the distal end of the cannula **805** position near the inner anterior wall of the annulus **888**. FIG. 8C illustrates FIG. 8A with a guidewire used to insert the laterovertically expandable frame **749** into the funnel **820** of the cannula **805** to guide the frame **749** into the annulus **888** in the low profile, collapsed state of the frame **749**. FIG. 8D illustrates an expansion handle **855** having trigger **856** that pushes a pushrod **857** along the guidewire **866** while holding the guidewire to push on the proximal end of the central beam **701** to insert the central beam **701** into the frame **749** to expand the frame **749** by applying equal, or substantially equal forces: a proximally-directed force,  $F_{sub.P}$ , at the connection **708** between the guide plate **707** and the guide wire **866** onto the distal portion of the beams of the frame **749**, and a distally-directed force,  $F_{sub.D}$ , at the proximal end of the central beam **701**.

(75) FIGS. 9A-9C illustrate the expansion of a laterovertically-expandable frame in an intervertebral space, according to some embodiments. FIG. 9A shows a collapsed frame **949** receiving a central beam **901** along a guidewire **966**. FIG. 9B shows the central beam **901** partially inserted into the frame **949** in an expanded state, the guidewire **966** still in place FIG. 9C shows how the expanded state may appear when inserted posterolaterally and expanded in the intervertebral space in an annulus **988**. Side ports **942,943** for bone graft distribution are shown through an open bone graft window in the expanded frame **749**.

(76) FIGS. 10A-10C illustrate profiles of an expanded graft distribution system to highlight the exit ports and bone graft windows, according to some embodiments. Profiles of an expanded frame **1049**, highlighting bone graft windows **1088** and graft ports **1040, 1041, 1042, 1043** as they may appear in an intervertebral space after an implant procedure. The guidewire **1066** is shown as remaining in place.

(77) FIGS. 11A and 11B compare an illustration of the graft distribution in place to a test placement in a cadaver to show relative size, according to some embodiments. Likewise, FIGS. 12A-12C show x-rays of a placement in a cadaver, according to some embodiments.

(78) As described above, the frame **149** can be configured such that the central axis of the first top beam **150** is at least substantially on (i) the top plane and (ii) the first side plane; the central axis of the second top beam **160** is at least substantially on (i) the top plane and (ii) the second side plane; the central axis of the first bottom beam **170** is at least substantially on (i) the bottom plane and (ii) the first side plane; and, the central axis of the second bottom beam being at least substantially on (i) the bottom plane and (ii) the second side plane. It should be appreciated that this configuration

provides a “top face” framed by the first top beam and the second top beam, a “bottom face” framed by the first bottom beam and the second bottom beam, a “first side face” framed by the first top beam and the first bottom beam, and a “second side face” framed by the second top beam and the second bottom beam.

(79) In some embodiments, it can be desirable to have the frame expand to shape that is predesigned to fit between the top endplate and the bottom endplate of the intervertebral space in a manner that calls, for example, for opposing faces of the frames to be something other than “at least substantially parallel.” For example, it may be desired to have the two opposing sides of the frame expand such that the central axis of the first top beam is no longer at least substantially parallel to the central axis of the second top beam. Likewise, it may be desired to have the two opposing sides of the frame expand such that the central axis of the first bottom beam is no longer at least substantially parallel to the central axis of the second bottom beam. Likewise, it may be desired to have the opposing top and bottom sides of the frame expand such that the central axis of the first top beam is no longer at least substantially parallel to the central axis of the first bottom beam. Likewise, it may be desired to have the opposing top and bottom sides of the frame expand such that the central axis of the second top beam is no longer at least substantially parallel to the central axis of the second bottom beam. Or, any combination of the above may be desired. The lateroververtically expandable frames taught herein enable each of these desirable configurations.

(80) FIGS. 13A-13D show orientations of the first top beam relative to the second top beam, first bottom beam relative to the second bottom beam, first top beam relative to the first bottom beam, and the second top beam relative to the second bottom beam, according to some embodiments. FIG. 13A shows the first top beam **150** relative to the second top beam **160**, in which the angle  $\theta_{sub.T}$  is formed by the two beams to shape the top face of the frame. FIG. 13B shows the first bottom beam **170** relative to the second bottom beam **180**, in which the angle  $\theta_{sub.B}$  is formed by the two beams to shape the bottom face of the frame. FIG. 13C shows the first top beam **150** relative to the first bottom beam **170**, in which the angle  $\theta_{sub.FS}$  is formed by the two beams to shape the first side face of the frame. FIG. 13D shows the second top beam **160** relative to the second bottom beam **180**, in which the angle  $\theta_{sub.SS}$  is formed by the two beams to shape the second side face of the frame. In some embodiments, each of  $\theta_{sub.T}$ ,  $\theta_{sub.B}$ ,  $\theta_{sub.FS}$ , and  $\theta_{sub.SS}$  can be independently selected and each can range from  $0^\circ$  to  $32^\circ$ , from  $0.5^\circ$  to  $31.5^\circ$ , from  $0.1^\circ$  to  $31.0^\circ$ , from  $1.5^\circ$  to  $30.5^\circ$ , from  $2.0^\circ$  to  $30.0^\circ$ , from  $2.5^\circ$  to  $29.5^\circ$ , from  $3.0^\circ$  to  $29.0^\circ$ , from  $3.5^\circ$  to  $28.5^\circ$ , from  $4.0^\circ$  to  $28.0^\circ$ , from  $4.5^\circ$  to  $27.5^\circ$ , from  $5.0^\circ$  to  $27^\circ$ , from  $5.5^\circ$  to  $26.5^\circ$ , from  $6.0^\circ$  to  $26.0^\circ$ , from  $6.5^\circ$  to  $25.5^\circ$ , from  $7.0^\circ$  to  $25.0^\circ$ , from  $7.5^\circ$  to  $25.5^\circ$ , from  $8.0^\circ$  to  $26.0^\circ$ , from  $8.5^\circ$  to  $26.5^\circ$ , from  $9.0^\circ$  to  $26.0^\circ$ , from  $9.5^\circ$  to  $25.5^\circ$ , from  $10.0^\circ$  to  $25.0^\circ$ , from  $10.5^\circ$  to  $24.5^\circ$ , from  $11.0^\circ$  to  $24.0^\circ$ , from  $11.5^\circ$  to  $23.5^\circ$ , from  $12.0^\circ$  to  $23.0^\circ$ , from  $12.5^\circ$  to  $22.5^\circ$ , from  $13.0^\circ$  to  $22.0^\circ$ , from  $13.5^\circ$  to  $21.5^\circ$ , from  $14.5^\circ$  to  $21.0^\circ$ , from  $15.5^\circ$  to  $20.5^\circ$ , from  $16.0^\circ$  to  $20.0^\circ$ , from  $16.5^\circ$  to  $19.5^\circ$ , from  $17.0^\circ$  to  $19.0^\circ$ , or any range therein in increments of  $0.1^\circ$ . In some embodiments, each of  $\theta_{sub.T}$ ,  $\theta_{sub.B}$ ,  $\theta_{sub.FS}$ , and  $\theta_{sub.SS}$  can be independently selected and each can be about  $1^\circ$ ,  $2^\circ$ ,  $3^\circ$ ,  $4^\circ$ ,  $5^\circ$ ,  $6^\circ$ ,  $7^\circ$ ,  $8^\circ$ ,  $9^\circ$ ,  $10^\circ$ ,  $11^\circ$ ,  $12^\circ$ ,  $13^\circ$ ,  $14^\circ$ ,  $15^\circ$ ,  $16^\circ$ ,  $17^\circ$ ,  $18^\circ$ ,  $19^\circ$ ,  $20^\circ$ ,  $21^\circ$ ,  $22^\circ$ ,  $23^\circ$ ,  $24^\circ$ ,  $25^\circ$ ,  $26^\circ$ ,  $27^\circ$ ,  $28^\circ$ ,  $29^\circ$ ,  $30^\circ$ ,  $31^\circ$ ,  $32^\circ$ ,  $33^\circ$ ,  $34^\circ$ ,  $35^\circ$ , or any angle therein in increments of  $0.1^\circ$ .

(81) It should be appreciated that the beams can each be independently designed to have its own, independently selected curvature, whether convex or concave, and the curvatures can be the same or different between beams that share a face of the frame. And, the curvatures can be opposing for beams that form opposing faces of the frame. Moreover, the frame can have a mixture of one or more straight and one or more curved beams.

(82) Given the above, it should be appreciated that the frames can be designed according to nearly any opening bordered by the top vertebral endplate and bottom vertebral endplate of an intervertebral space, as well as according to a given clinical treatment regardless of the opening dimensions prior to treatment. In some embodiments, the top face of the frame can be at least substantially parallel to the bottom face of the frame, whereas the first side face of the frame and

the second side face of the frame can be oriented at angles  $\theta_{\text{sub.T}}$  and  $\theta_{\text{sub.B}}$ , wherein  $\theta_{\text{sub.T}}$  and  $\theta_{\text{sub.B}}$  can be independently selected to be the same or different. Likewise, in some embodiments, the first side face of the frame can be at least substantially parallel to the second side face of the frame, whereas the top face of the frame and the bottom face of the frame can be oriented at angles  $\theta_{\text{sub.FS}}$  and  $\theta_{\text{sub.SS}}$ , wherein  $\theta_{\text{sub.FS}}$  and  $\theta_{\text{sub.SS}}$  can be independently selected to be the same or different. In some embodiments, each of  $\theta_{\text{sub.T}}$ ,  $\theta_{\text{sub.B}}$ ,  $\theta_{\text{sub.FS}}$ , and  $\theta_{\text{sub.SS}}$  can be independently selected to range from about  $5^\circ$  to about  $32^\circ$ , from about  $7^\circ$  to about  $22^\circ$ , and from about  $8^\circ$  to about  $16^\circ$ , in some embodiments. As such, any of a variety of frames can be constructed from any of a variety of quadrilateral structures having the angles taught herein.

(83) In some embodiments, the systems include a stabilizer that slidably engages with the distal region of the first top beam, the first bottom beam, the second top beam, the second bottom beam, or a combination thereof. The stabilizer serves the function of the guide plate taught herein and can also be configured for retaining the first top beam, the first bottom beam, the second top beam, the second bottom beam, or the combination thereof, from a lateral movement that exceeds the expanded state.

(84) And, in some embodiments, the framing can be configured for engaging with the central beam in vivo to support the framing in the expanded state. Moreover, the connector elements can be struts configured to have a cross-sectional aspect ratio of longitudinal thickness to transverse thickness ranging from 1:2 to 1:8, adapted to maintain structural stiffness in the laterovertically expanding frame in a direction perpendicular to the central frame axis of the expanded state of the frame.

(85) FIGS. 14A-14D illustrate components of a system having a stabilizer, wherein the stabilizer is in an X-configuration, according to some embodiments. As shown in FIG. 14A, the system **1400** can include a stabilizer **1407** that can be in an X-configuration. In some embodiments, the X-configuration can have a first top leg TL.sub.1 for slidably-engaging with the first top beam **1450** at an angle  $\theta_{\text{sub.1T}}$  with the intended lateral movement LM.sub.1T of the first top beam **1450**, first bottom leg BL.sub.1 for slidably engaging with the first bottom beam **1470** at an angle  $\theta_{\text{sub.1B}}$  with the intended lateral movement LM.sub.1B of the first bottom beam **1470**, a second top leg TL.sub.2 for slidably engaging with the second top beam **1460** at an angle  $\theta_{\text{sub.2T}}$  with the intended lateral movement LM.sub.2T of the second top beam **1460**, and a second bottom leg BL.sub.2 for slidably engaging with the second bottom beam **1480** at an angle  $\theta_{\text{sub.2B}}$  with the intended lateral movement LM.sub.2B of the second bottom beam **1480**.

(86) In some embodiments, each of the angles  $\theta_{\text{sub.1T}}$ ,  $\theta_{\text{sub.1B}}$ ,  $\theta_{\text{sub.2T}}$ ,  $\theta_{\text{sub.2B}}$ , respectively, provide a tensile force for resisting the first top beam **1450**, the first bottom beam **1470**, the second top beam **1460**, and the second bottom beam **1480** from the lateral movement LM.sub.1T, LM.sub.2T, LM.sub.1B, LM.sub.2B that exceeds the expanded state. In some embodiments, each of the angles  $\theta_{\text{sub.1T}}$ ,  $\theta_{\text{sub.1B}}$ ,  $\theta_{\text{sub.2T}}$ ,  $\theta_{\text{sub.2B}}$  can be independently selected from an amount of angulation ranging from about  $15^\circ$  to about  $75^\circ$ , from about  $20^\circ$  to about  $75^\circ$ , from about  $25^\circ$  to about  $75^\circ$ , from about  $30^\circ$  to about  $75^\circ$ , from about  $35^\circ$  to about  $75^\circ$ , from about  $55^\circ$  to about  $75^\circ$ , from about  $15^\circ$  to about  $70^\circ$ , from about  $15^\circ$  to about  $65^\circ$ , from about  $15^\circ$  to about  $60^\circ$ , from about  $15^\circ$  to about  $55^\circ$ , from about  $15^\circ$  to about  $50^\circ$ , from about  $15^\circ$  to about  $45^\circ$ , or any range therein. In some embodiments, each of the angles  $\theta_{\text{sub.1T}}$ ,  $\theta_{\text{sub.1B}}$ ,  $\theta_{\text{sub.2T}}$ ,  $\theta_{\text{sub.2B}}$  can be independently selected from an amount of angulation that is about  $10^\circ$ , about  $15^\circ$ , about  $20^\circ$ , about  $25^\circ$ , about  $30^\circ$ , about  $35^\circ$ , about  $40^\circ$ , about  $45^\circ$ , about  $50^\circ$ , about  $55^\circ$ , about  $60^\circ$ , about  $65^\circ$ , about  $70^\circ$ , about  $75^\circ$ , about  $80^\circ$ , or any angulation therein in amounts of  $1^\circ$ .

(87) In some embodiments, the stabilizer **1407** further comprises a point of attachment **1408** for releasably attaching a guidewire (not shown) for guiding the central beam **1401** into the laterovertically expanding frame comprising the first top beam **1450**, the second top beam **1460**, the first bottom beam **1470**, and the second bottom beam **1480**. And, in some embodiments, the first top leg TL.sub.1, the first bottom leg BL.sub.1, the second top leg TL.sub.2, and the second

bottom leg BL.sub.2 converge to form a hub **1408H** having a point of attachment **1408** on the posterior surface of the hub **1408H** for releasably attaching a guidewire (not shown) for guiding the central beam **1401** into the lateroververtically expanding frame. The point of attachment might be, for example, a male or female threaded component, or any other releasable connector known to one of skill. And, the beams **1450, 1460, 1470, 1480** can be configured with ports TP.sub.1, TP.sub.2, BP.sub.1, BP.sub.2 for passage of the respective legs TL.sub.1, TL.sub.2, BL.sub.1, BL.sub.2 of the stabilizer **1407**. FIGS. **14B** and **14C** show the system in a collapsed configuration and expanded side configuration, respectively. In some embodiments, the central beam **1401** can include one or more bone graft distribution ports **1466**. And, as in other embodiments taught herein, the beams **1450, 1460, 1470, 1480** can be interconnected using flexible struts **1495**.

(88) FIGS. **15A-15D** illustrate components of a system having a stabilizer, wherein the stabilizer is in an H-configuration, according to some embodiments. The H-configuration can have a first vertical leg VL.sub.1, a second vertical leg VL.sub.2, and a cross-member CM that connects the first vertical leg VL.sub.1 at least substantially parallel to the second vertical leg VL.sub.2, the first vertical leg VL.sub.1 including a first retaining surface RS.sub.1 for engaging with the first top beam **1550** and the first bottom beam **1570**, the second vertical leg VL.sub.2 including a second retaining surface RS.sub.2 for engaging with the second top beam **1560** and the second bottom beam **1580**, and the cross member CM providing a tensile force for resisting the first top beam **1550**, the first bottom beam **1570**, the second top beam **1560**, and the second bottom beam **1580** from the lateral movement that exceeds the expanded state. In some embodiments, the central beam **1501** has a horizontal groove HG configured complementary to the cross-member CM of the stabilizer **1507**, and the horizontal groove HG of the central beam **1501** slidably connects with the cross-member CM in the expanded state. In some embodiments, the cross-member CM further comprises a vertical support member VSM and the central beam **1501** has a vertical groove VG configured complementary to the vertical support member VSM of the stabilizer, and the vertical groove VG of the central beam **1501** slidably connects with the vertical support member VSM in the expanded state. In some embodiments, the stabilizer **1507** further comprises a point of attachment **1508** at a hub **1508H** for releasably attaching a guidewire (not shown) adapted for guiding the central beam **1501** into the lateroververtically expanding frame comprising the first top beam **1550**, the second top beam **1560**, the first bottom beam **1570**, and the second bottom beam **1580**. guidewire (not shown) for guiding the central beam **1501** into the lateroververtically expanding frame. The point of attachment might be, for example, a male or female threaded component, or any other releasable connector known to one of skill. And, the beams **1550, 1560, 1570, 1580** can be configured with slots S.sub.1, S.sub.2 in which the vertical legs VL.sub.1, VL.sub.2 can travel during the lateral expansion of the beams **1550, 1560, 1570, 1580** of the expandable frame. And, in some embodiments, cross-member CM includes a first pillar P.sub.1 and a second pillar P.sub.2 that operably connect at a hub that has the point of attachment **1508** for releasably attaching the guidewire (not shown) for guiding the central beam **1501** into the lateroververtically expanding frame. In some embodiments, the central beam **1501** can include one or more bone graft distribution ports **1566**. And, as in other embodiments taught herein, the beams **1550, 1560, 1570, 1580** can be interconnected using flexible struts **1595**.

(89) One of skill will appreciate that the teachings provided herein are directed to basic concepts that can extend beyond any particular embodiment, embodiments, figure, or figures. It should be appreciated that any examples are for purposes of illustration and are not to be construed as otherwise limiting to the teachings. For example, it should be appreciated that the devices provided herein can also be used as implants in other areas of the body. The devices provided herein can be used, for example, in intravertebral body procedures to support or distract vertebral bodies in the repair of, for example, collapsed, damaged or unstable vertebral bodies suffering from disease or injury.

## Claims

1. A method of stabilizing a laterally-expandable intervertebral scaffolding in a subject, the method comprising: obtaining a laterally-expandable intervertebral scaffolding having a plurality of support beams each beam in the plurality of support beams (i) designed to bear a compression load in the cephalocaudal direction in a subject and (ii) independently selected from the group consisting of straight beams and curved beams; and, expanding the scaffolding in the subject in operable connection with a stabilizer that slidably engages with the support beams and provides an opposing force to each beam in the plurality of support beams during the expanding, the opposing force retaining each beam in the plurality of support beams from a lateral movement that exceeds the expanded state.
2. The method of claim 1, further comprising: selecting the intervertebral scaffolding to include an assembly of 4 independently operable, structural beams in an at least substantially parallel orientation for an expansion of the assembly from a collapsed state to an expanded state; wherein, the assembly includes a first top beam, a second top beam, a first bottom beam, and a second bottom beam, each beam having a central axis and designed to bear the compression load in the cephalocaudal direction in a subject, the compression load applied at least substantially normal to the central axis of each beam in an intervertebral space of the subject.
3. The method of claim 2, further comprising: selecting the stabilizer to include an X-configuration having a first top leg for slidably-engaging with the first top beam at an angle  $\theta_{\text{sub.1T}}$  with the lateral movement of the first top beam, first bottom leg for slidably engaging with the first bottom beam at an angle  $\theta_{\text{sub.1B}}$  with the lateral movement of the first bottom beam, a second top leg for slidably engaging with the second top beam at an angle  $\theta_{\text{sub.2T}}$  with the lateral movement of the second top beam, and a second bottom leg for slidably engaging with the second bottom beam at an angle  $\theta_{\text{sub.2B}}$  with the lateral movement of the second bottom beam; wherein, each of the angles  $\theta_{\text{sub.1T}}$ ,  $\theta_{\text{sub.1B}}$ ,  $\theta_{\text{sub.2T}}$ ,  $\theta_{\text{sub.2B}}$ , respectively, provides a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from a lateral movement that exceeds the expanded state.
4. The method of claim 2, further comprising: selecting the stabilizer with an X-configuration having a first top leg for slidably-engaging with the first top beam at an angle  $\theta_{\text{sub.1T}}$  with the lateral movement of the first top beam, first bottom leg for slidably engaging with the first bottom beam at an angle  $\theta_{\text{sub.1B}}$  with the lateral movement of the first bottom beam, a second top leg for slidably engaging with the second top beam at an angle  $\theta_{\text{sub.2T}}$  with the lateral movement of the second top beam, and a second bottom leg for slidably engaging with the second bottom beam at an angle  $\theta_{\text{sub.2B}}$  with the lateral movement of the second bottom beam, wherein each of the angles  $\theta_{\text{sub.1T}}$ ,  $\theta_{\text{sub.1B}}$ ,  $\theta_{\text{sub.2T}}$ ,  $\theta_{\text{sub.2B}}$ , respectively, provides a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from a lateral movement that exceeds the expanded state; and, obtaining a rigid expansion member for expansion of the beams and retention by the stabilizer.
5. The method of claim 2, wherein the obtaining further comprises selecting the stabilizer with a first top leg for slidably-engaging with the first top beam at an angle  $\theta_{\text{sub.1T}}$  with the lateral movement of the first top beam; a first bottom leg for slidably engaging with the first bottom beam at an angle  $\theta_{\text{sub.1B}}$  with the lateral movement of the first bottom beam; a second top leg for slidably engaging with the second top beam at an angle  $\theta_{\text{sub.2T}}$  with the lateral movement of the second top beam; and, a second bottom leg for slidably engaging with the second bottom beam at an angle  $\theta_{\text{sub.2B}}$  with the lateral movement of the second bottom beam; wherein each of the angles  $\theta_{\text{sub.1T}}$ ,  $\theta_{\text{sub.1B}}$ ,  $\theta_{\text{sub.2T}}$ ,  $\theta_{\text{sub.2B}}$ , respectively, is  $>0$  and provides a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from a lateral movement that exceeds the expanded state.

6. The method of claim 2, wherein the obtaining further comprises selecting the stabilizer with a first vertical leg, a second vertical leg, and a cross-member that connects the first vertical leg to the second vertical leg, the first vertical leg including a retaining surface for engaging with the first top beam and the first bottom beam, the second vertical leg including a retaining surface for engaging with the second top beam and the second bottom beam, and the cross member providing a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from a lateral movement that exceeds the expanded state.

7. The method of claim 2, wherein the obtaining further comprises selecting the stabilizer with a first vertical leg, a second vertical leg, and a cross-member that connects the first vertical leg to the second vertical leg, the first vertical leg including a retaining surface for engaging with the first top beam and the first bottom beam, the second vertical leg including a retaining surface for engaging with the second top beam and the second bottom beam, and the cross member providing a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from a lateral movement that exceeds the expanded state; and, obtaining a rigid expansion member for expansion of the beams and retention by the stabilizer.

8. The method of claim 2, further comprising: selecting the stabilizer to have a first vertical leg, a second vertical leg, a cross-member that connects the first vertical leg at least substantially parallel to the second vertical leg, the first vertical leg including a retaining surface for engaging with the first top beam and the first bottom beam, the second vertical leg including a retaining surface for engaging with the second top beam and the second bottom beam, and the cross member providing a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from the lateral movement that exceeds the expanded state; and, a point of attachment for releasably attaching a guidewire adapted for guiding an expansion member into the laterally expandable scaffolding.

9. The method of claim 2, further comprising: selecting the stabilizer to have an H-configuration having a first vertical leg, a second vertical leg, a cross-member that connects the first vertical leg at least substantially parallel to the second vertical leg, the first vertical leg including a retaining surface for engaging with the first top beam and the first bottom beam, the second vertical leg including a retaining surface for engaging with the second top beam and the second bottom beam, and the cross member providing a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from the lateral movement that exceeds the expanded state.

10. The method of claim 2, further comprising adding a top connector element that is configured to expandably connect the first top beam to the second top beam to form a top plane; and, adding a bottom connector element that is configured to expandably connect the first bottom beam to the second bottom beam to form a bottom plane; wherein, the top connector element and the bottom connector each operate independently of the stabilizer.

11. The method of claim 2, further comprising adding a first side connector element configured to expandably connect the first top beam to the first bottom beam; and, adding a second side connector element configured to expandably connect the second top beam to the second bottom beam; wherein, the top connector element is configured monolithically integral to the first top beam and the second top beam; the bottom connector element is configured monolithically integral to the first bottom beam and the second bottom beam; the first side connector element is configured monolithically integral to the first top beam and the second top beam; the second side connector element is configured monolithically integral to the first bottom beam and the second bottom beam; wherein, the top connector element, the bottom connector element, the first side connector element, and the second side connector element each operate independently of the stabilizer.

12. The method of claim 1 further comprising obtaining a rigid expansion member having a grafting port.

13. A method of fusing an intervertebral space with a stabilized intervertebral scaffolding, the

method comprising: obtaining a laterally expandable intervertebral scaffolding having a collapsed state, an expanded state, and a plurality of support beams, each beam in the plurality of beams designed to bear a compression load in the cephalocaudal direction in a subject; creating a point of entry into an intervertebral disc, the intervertebral disc having a nucleus pulposus surrounded by an annulus fibrosis; removing the nucleus pulposus from within the intervertebral disc through the point of entry, leaving the intervertebral space for expansion of the scaffolding within the annulus fibrosis, the intervertebral space having a top vertebral plate and a bottom vertebral plate; inserting the laterally expandable intervertebral scaffolding in the collapsed state through the point of entry into the intervertebral space; expanding the scaffolding in the presence of a stabilizer providing an opposing lateral force to a respective support beam during the expansion of the assembly, the opposing lateral force retaining the respective support beam from the lateral movement that exceeds the expanded state in the subject; and, adding a grafting material to the intervertebral space.

14. The method of claim 13, wherein the creating of the point of entry comprises creating a lateral dimension of the point of entry ranging from about 5 mm to about 15 mm, and the amount of lateral expansion is selected to exceed the lateral dimension of the point of entry.

15. The method of claim 13, wherein the expanding includes: expanding the laterally expandable intervertebral scaffolding laterally to a width that exceeds the width of the point of entry.

16. The method of claim 13, wherein the expanding of the laterally expandable intervertebral scaffolding includes inserting an expansion member that is sized to expand the scaffolding laterally within the stabilizer for the retaining; and, engaging a means for preventing the expansion member from backing out of the laterally expandable intervertebral scaffolding after the expanding.

17. A kit, comprising: a laterally expandable intervertebral scaffolding having a collapsed state, an expanded state, and a plurality of support beams, each beam in the plurality of support beams designed to bear a compression load in the cephalocaudal direction in a subject; a stabilizer providing an opposing lateral force to a respective support beam during the expansion of the scaffolding, the opposing lateral force retaining the respective support beam from a lateral movement that exceeds the expanded state; and, a guidewire adapted for guiding an expansion member into the laterally expandable scaffolding; wherein: the laterally expandable scaffolding has 4 independently operable beams in an at least substantially parallel orientation, the beams including a first top beam, a second top beam, a first bottom beam, and a second bottom beam; and, the stabilizer has an X-configuration with a first top leg for slidably-engaging with the first top beam at an angle  $\theta_{\text{sub.1T}}$  with the lateral movement of the first top beam, first bottom leg for slidably engaging with the first bottom beam at an angle  $\theta_{\text{sub.1B}}$  with the lateral movement of the first bottom beam, a second top leg for slidably engaging with the second top beam at an angle  $\theta_{\text{sub.2T}}$  with the lateral movement of the second top beam, and a second bottom leg for slidably engaging with the second bottom beam at an angle  $\theta_{\text{sub.2B}}$  with the lateral movement of the second bottom beam, wherein each of the angles  $\theta_{\text{sub.1T}}$ ,  $\theta_{\text{sub.1B}}$ ,  $\theta_{\text{sub.2T}}$ ,  $\theta_{\text{sub.2B}}$ , respectively, provides a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from a lateral movement that exceeds the expanded state.

18. The kit of claim 17, wherein: the laterally expanding scaffolding has 4 independently operable beams in an at least substantially parallel orientation, the beams including a first top beam, a second top beam, a first bottom beam, and a second bottom beam; and, the stabilizer has a first top leg for slidably-engaging with the first top beam at an angle  $\theta_{\text{IT}}$  with the lateral movement of the first top beam; a first bottom leg for slidably engaging with the first bottom beam at an angle  $\theta_{\text{sub.1B}}$  with the lateral movement of the first bottom beam; a second top leg for slidably engaging with the second top beam at an angle  $\theta_{\text{sub.2T}}$  with the lateral movement of the second top beam; and, a second bottom leg for slidably engaging with the second bottom beam at an angle  $\theta_{\text{2B}}$  with the lateral movement of the second bottom beam; wherein each of the angles  $\theta_{\text{sub.1T}}$ ,  $\theta_{\text{sub.1B}}$ ,  $\theta_{\text{sub.2T}}$ ,  $\theta_{\text{sub.2B}}$ , respectively, is  $>0$  and provides a tensile force for resisting the first top beam,

the first bottom beam, the second top beam, and the second bottom beam from a lateral movement that exceeds the expanded state.

19. The kit of claim 17, wherein: the laterally expandable scaffolding has 4 independently operable beams in an at least substantially parallel orientation, the beams including a first top beam, a second top beam, a first bottom beam, and a second bottom beam; and, the stabilizer has a first vertical leg, a second vertical leg, and a cross-member that connects the first vertical leg to the second vertical leg, the first vertical leg including a retaining surface for engaging with the first top beam and the first bottom beam, the second vertical leg including a retaining surface for engaging with the second top beam and the second bottom beam, and the cross member providing a tensile force for resisting the first top beam, the first bottom beam, the second top beam, and the second bottom beam from a lateral movement that exceeds the expanded state.
