CONTROL SYSTEM WITH OCCUPANCY SENSING

Abstract

A load control system controls an electrical load provided in a space and comprises a load control device and one or more occupancy sensors. The load control device controls the load in response to the wireless control signals received from the occupancy sensors. Each occupancy sensor transmits an occupied control signal to the load control device in response to detecting an occupancy condition in the space and a vacant control signal to the load control device in response to detecting a vacancy condition. The load control device turns on the load in response to receiving the occupied control signal from at least one of the occupancy sensors, and turns off the load in response to receiving vacant control signals from both of the occupancy sensors. The load control device is operable to determine that no wireless control signals have been received from the occupancy sensors for the length of a predetermined timeout period and to subsequently turn off the load.

No. 8,009,042, issued Aug. 30, 2011, the contents of each are hereby incorporated by reference in their entirety.

BACKGROUND OF THE INVENTION

Field of the Invention

[0002] The present invention relates to occupancy and vacancy sensors for detecting an occupancy or a vacancy in a space, and more particularly, to a wireless load control system including a plurality of battery-powered occupancy or vacancy sensors for detecting an occupancy or a vacancy in a space, and a load control device for controlling the amount of power delivered to an electrical load in response to the occupancy or vacancy sensors.

Description of the Related Art

[0003] Occupancy and vacancy sensors are often used to detect occupancy and/or vacancy conditions in a space in order to control an electrical load, such as, for example, a lighting load. An occupancy sensor typically operates to turn on the lighting load when the occupancy sensor detects the presence of a user in the space (i.e., an occupancy event) and then to turn off the lighting load when the occupancy sensor detects that the user has left the space (i.e., a vacancy event). A vacancy

sensor only operates to turn off the lighting load when the vacancy sensor detects a vacancy in the space. Therefore, when using a vacancy sensor, the lighting load must be turned on manually (e.g., in response to a manual actuation of a control actuator).

[0004] Occupancy and vacancy sensors have often been provided in wall-mounted load control devices that are coupled between an alternating-current (AC) power source and an electrical load for control of the amount of power delivered to the electrical load. Such wall-mounted load control devices typically comprise internal detectors, such as, for example, a pyroelectric infrared (PIR) detector, and a lens for directing energy to the PIR detector for detecting the presence of the user in the space. However, since the wall-mounted load control devices are mounted to a wall in a standard electrical wallbox (i.e., replacing a standard light switch), the detection of energy by the PIR detector may be hindered due to the direction that the load control device is facing and by obstacles in the space, thus increasing the likelihood that the load control device may not detect the presence of a user.

[0005] Some prior art occupancy and vacancy sensors have been provided as part of lighting control systems. These sensors are typically coupled via a wired control link to a lighting controller (e.g., a central processor), which then controls the lighting loads accordingly. Since the control link is typically a low-voltage control link, these occupancy and vacancy sensors are not required to be mounted in electrical wallboxes, but may be mounted to the ceiling or high on a wall. Therefore, the occupancy and vacancy sensors may be positioned optimally to detect the presence of the user in all areas of the space. However, these prior art lighting control systems require advanced system components and configuration procedures in order to operate properly.

[0006] Thus, there is a need for a simple lighting control system that has occupancy or vacancy sensors which may be easily and optimally installed into a space.

SUMMARY OF THE INVENTION

[0007] According to an embodiment of the present invention, a radio-frequency load control system with occupancy sensing comprises a load control device and first and second battery-powered occupancy sensors. The load control device is connected between an AC power source and an electrical load, and contains a radio-frequency (RF) receiver circuit for receiving radio frequency signals. Each of the first and second battery-powered occupancy sensors are fixable to a surface of a room in which the electrical load is located for transmitting an RF signal in response to the presence of an occupant in the room. The second occupancy sensor is spaced from the location of the first occupancy sensor. Each occupancy sensor comprises an enclosed plastic housing including at least one battery, a detector for sensing the presence or absence of occupants in the room, and a RF transmitter circuit for producing the RF signal which is modulated to indicate the presence or absence of the occupant in the room, the RF signals of the occupancy sensors having respective identifying information to identify themselves to the load control device. The load control device receives the RF signals transmitted by the occupancy sensors and controls the current supplied to the electrical load in a predetermined dependence on the detection of an occupancy or a vacancy in the room.

[0008] According to another embodiment of the present invention, a load control system for controlling the amount of power delivered from an AC power source to an electrical load provided in a space comprises two occupancy sensors and a load control device operable to enable the delivery of power to the electrical load in response to receiving an occupied wireless control signal from at least one of the occupancy sensors, and to cease the delivery of power to the electrical load in response to receiving vacant control signals from both of the occupancy sensors. The load control device is adapted to be coupled in series electrical connection between the AC power source and the electrical load for control of the amount of power delivered to the electrical load. The load control device receives wireless control signals and controls the amount of power delivered to the electrical load in response to the wireless control signals. Each of the two occupancy sensors independently detects an occupancy condition in the space, transmits the

occupied wireless control signal to the load control device in response to detecting the occupancy condition, and transmits the vacant wireless control signal to the load control device in response to detecting a vacancy condition in the space.

[0009] In addition, a method of controlling the amount of power delivered from an A C power source to an electrical load provided in a space comprises the steps of: (1) providing two occupancy sensors in the space; (2) detecting by one of the occupancy sensors an occupancy condition in the space; (3) transmitting by one of the occupancy sensors an occupied wireless control signal in response to the step of detecting the occupancy condition; (4) receiving the occupied wireless control signal from at least one of the occupancy sensors; (5) enabling the delivery of power to the electrical load in response to the step of receiving the occupied wireless control signal from at least one of the occupancy sensors; (6) detecting by one of the occupancy sensors a vacancy condition in the space; (7) transmitting by one of the occupancy sensors a vacant wireless control signal in response to the step of detecting a vacancy condition in the space; (8) receiving vacant control signals from both of the occupancy sensors; and (9) ceasing the delivery of power to the electrical load in response to the step of receiving vacant control signals from both of the occupancy sensors.

[0010] A sensor system for controlling a lighting load located within a room is also described herein. The sensor system comprises an RF-responsive light control device for turning on and turning off the lighting load, and at least first and second spaced occupancy sensors disposed to monitor occupancy in different areas of the room. Each of the first and second sensors produce first and second respective occupied and vacant RF signals to the light control device in response to the sensing of a respective presence or absence of an occupant in the room. The light control device turns on the lighting load in response to receiving an occupied RF signal from either of the first or second sensors, and turns off the lighting load in response to receiving an vacant RF signal from both of the sensors.

[0011] Further, a process of controlling a lighting load in a room dependent upon the occupancy or vacancy of the room comprises the steps of: (1) providing first and second spaced occupancy sensors mounted within the room; (2) monitoring by the first and second occupancy sensors for the presence of one or more persons in the room; (3) transmitting by the first and second occupancy sensors respective RF signals including occupancy or vacancy information with an identifier of the respective sensor producing such information; (4) receiving the RF signals by a load control device; (5) turning on by the load control device the lighting load in response to receiving an occupied RF output signal from either the first or the second sensor; and (6) turning off by the load control device the lighting load in response to receiving vacant RF signals from both of the first and second sensors.

[0012] According to another embodiment of the present invention, a load control system for controlling the amount of power delivered from an AC power source to an electrical load provided in a space comprises an occupancy sensor and a load control device operable to determine that no wireless control signals have been received from the occupancy sensor for the length of a predetermined timeout period and to subsequently cease the delivery of power to the electrical load. The load control device receives the wireless control signals and controls the amount of power delivered to the electrical load in response to the wireless control signals. The occupancy sensor detects an occupancy condition in the space and transmits a first wireless control signal to the load control device in response to detecting the occupancy condition, and transmits a second wireless control signal to the load control device in response to detecting a continued occupancy condition in the space. The load control device enables the delivery of power to the electrical load in response to the first wireless control signal, determines that no wireless control signals have been received from the occupancy sensor for the length of the predetermined timeout period, and subsequently ceases the delivery of power to the electrical load.

[0013] In addition, a method of controlling the amount of power delivered from an AC power source to an electrical load provided in a space comprises the steps of: (1) providing an occupancy

sensor in the space; (2) detecting by the occupancy sensor an occupancy condition in the space; (3) transmitting by the occupancy sensor a first wireless control signal in response to the step of detecting the occupancy condition; (4) enabling the delivery of power to the electrical load in response to the first wireless control signal; (5) detecting by the occupancy sensor a continued occupancy condition in the space; (6) transmitting by the occupancy sensor a second wireless control signal in response to the step of detecting a continued occupancy condition in the space; (7) determining that no wireless control signals have been received from the occupancy sensor for the length of a predetermined timeout period; and (8) ceasing the delivery of power to the electrical load in response to the step of determining that no wireless control signals have been received.

[0014] According to another embodiment of the present invention, a load control system for controlling the amount of power delivered from an AC power source to an electrical load provided in a space comprises a load control device an occupancy sensor comprising an occupancy detector for detecting an occupancy condition in the space and an ambient light level detector for measuring the ambient light level in the space. The load control device receives wireless control signals and controls the amount of power delivered to the electrical load in response to the wireless control signals. The occupancy sensor compares the ambient light level to an ambient light level threshold, transmits a first predetermined wireless control signal to the load control device in response to determining that the ambient light level is less than the threshold, and transmits a second predetermined wireless control signal to in response to determining that the ambient light level is greater than the threshold.

[0015] In addition, a wall or ceiling mounted occupancy sensor comprises: (1) at least one battery; (2) a controller coupled to the battery; (3) a PIR occupancy detector for sensing the presence or absence of an occupant in a room, the occupancy detector circuit coupled to the controller and delivering occupancy or vacancy information to the controller; (4) an RF transmitter coupled to the battery and the controller for transmitting an RF signal containing information related to the presence or absence of an occupant in the room; (5) an ambient light detector coupled to the controller, the controller compares the level of ambient light within the area to an ambient light threshold, whereby the RF signal transmitted by the RF transmitter is modified in accordance with the comparison of the level of ambient light within the area and the ambient light threshold; and (6) an enclosure housing containing the battery, the controller, and the PIR detector, the RF transmitter, and the ambient light detector, the housing having mounting structure for mounting the sensor to a wall or ceiling surface of a room.

[0016] According to another embodiment of the present invention, a load control system for controlling the amount of power delivered from an AC power source to an electrical load provided in a space comprises an occupancy sensor and a load control device operable to store operating characteristics of the load control system. The load control device receives wireless control signals and controls the amount of power delivered to the electrical load in response to the wireless control signals. The occupancy sensor comprises an occupancy detector circuit for generating an occupancy control signal representative of an occupancy condition in the space, a controller responsive to the occupancy control signal, and a wireless transmitter for transmitting the wireless control signals. The controller determines whether the occupancy condition is presently occurring in the space based upon each of a plurality of occupancy criteria and generates a result for each of the determinations of the occupancy condition at each of the plurality of occupancy criteria. The occupancy sensor transmits to the load control device each of the results of the determinations of the occupancy condition at each of the plurality of occupancy criteria. The load control device is characterized by a predetermined one of the plurality of occupancy criteria, and selects one of the results of each of the determinations of the occupancy condition at each of the plurality of occupancy criteria based upon the predetermined one of the plurality of occupancy criteria. The load control device controls the amount of power delivered to the electrical load in response to the selected results of the determination of the occupancy condition.

[0017] Further, a method of controlling the amount of power delivered from an AC power source to an electrical load provided in a space comprises the steps of: (1) generating an occupancy control signal representative of an occupancy condition in the space; (2) determining whether the occupancy condition is presently occurring in the space based upon each of a plurality of occupancy criteria; (3) generating a result for each of the determinations of the occupancy condition at each of the plurality of occupancy criteria; (4) transmitting each of the results of the determinations of the occupancy condition at each of the plurality of occupancy criteria; (5) selecting one of the results of each of the determinations of the occupancy condition at each of the plurality of occupancy criteria based upon a predetermined one of the plurality of occupancy criteria; and (6) controlling the amount of power delivered to the electrical load in response to the step of selecting one of the results.

[0018] Other features and advantages of the present invention will become apparent from the following description of the invention that refers to the accompanying drawings.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

[0019] FIG. 1A is a simple diagram of a radio-frequency (RF) lighting control system having a dimmer switch and remote occupancy sensors for control of the amount of power delivered to a lighting load according to a first embodiment of the present invention;

[0020] FIG. 1B is a simplified state diagram illustrating the operation of one of the occupancy sensors of the RF lighting control system of FIG. 1A;

[0021] FIG. 1C is a simplified state diagram illustrating the state of a failsafe timer of the dimmer switch of the RF lighting control system of FIG. 1A;

[0022] FIG. 1D is a simplified state diagram illustrating how the dimmer switch of the RF lighting control system of FIG. 1A controls the lighting load;

[0023] FIG. 2A is a simplified block diagram of the dimmer switch of the RF lighting control system of FIG. 1A;

[0024] FIG. 2B is a simplified block diagram of one of the remote occupancy sensors of the RF lighting control system of FIG. 1A;

[0025] FIG. 3 is a simplified circuit diagram of an occupancy detector circuit of the occupancy sensor of FIG. 2B;

[0026] FIG. 4A is a front exploded perspective view of the occupancy sensor of FIG. 2B;

[0027] FIG. 4B is a rear exploded perspective view of the occupancy sensor of FIG. 2B;

[0028] FIG. 4C is a perspective view of a multi-functional structure of the occupancy sensor of FIG. 2B;

[0029] FIG. 4D is a rear perspective view of a base portion of the occupancy sensor of FIG. 2B with batteries removed;

[0030] FIG. 5 is a flowchart of a rear actuator procedure executed by a controller of the occupancy sensor of FIG. 2B when an actuator on a rear surface of the base portion of FIG. 4D is pressed;

[0031] FIGS. 6A and 6B is a simplified flowchart of a dimmer actuator procedure executed by a controller of the dimmer switch of FIG. 2A;

[0032] FIG. 7 is a simplified flow chart of an assignment procedure executed by the controller of the dimmer switch of FIG. 2A;

[0033] FIG. 8 is a flowchart of an occupancy detection procedure executed periodically by the controller of the occupancy sensor of FIG. 2B according to the first embodiment of the present invention;

[0034] FIG. 9 is a flowchart of a transmission timer procedure executed by the controller of the occupancy sensor of FIG. 2B according to the first embodiment of the present invention;

[0035] FIG. **10** is a flowchart of an occupancy timer procedure executed by the controller of the occupancy sensor of FIG. **2B** according to the first embodiment of the present invention;
[0036] FIG. **11** is a flowchart of a received message procedure executed by the controller of the dimmer switch of FIG. **2A** according to the first embodiment of the present invention;
[0037] FIG. **12** is a simplified flowchart of a failsafe timer procedure executed by the controller according to the first embodiment of the present invention;
[0038] FIG. **13** is a flowchart of an occupancy detection procedure executed periodically by the controller of the occupancy sensor of FIG. **2B** according to a second embodiment of the present invention;

[0039] FIG. **14** is a flowchart of a transmission procedure executed by the controller of the occupancy sensor of FIG. **2B** according to the second embodiment of the present invention;
[0040] FIG. **15** is a flowchart of a received message procedure executed by the controller of the dimmer switch of FIG. **2A** according to the second embodiment of the present invention;
[0041] FIG. **16** is a flowchart of an occupancy timer procedure executed by the controller of the dimmer switch of FIG. **2A** according to the second embodiment of the present invention;
[0042] FIG. **17A** is a simplified block diagram of a lighting control system having a dimmer switch, remote occupancy sensors, and a remote control for controlling the amount of power delivered to a lighting load according to a third embodiment of the present invention;
[0043] FIG. **17B** is a simplified state diagram illustrating how the dimmer switch of the RF lighting control system of FIG. **17A** controls the lighting load;
[0044] FIG. **17C** is a simplified state diagram illustrating the state of a failsafe timer of one of the occupancy sensors of the RF lighting control system of FIG. **17A**; and
[0045] FIG. **18** is a simplified schematic diagram of an occupancy detector circuit **232'** according to a fourth embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0046] The foregoing summary, as well as the following detailed description of the preferred embodiments, is better understood when read in conjunction with the appended drawings. For the purposes of illustrating the invention, there is shown in the drawings an embodiment that is presently preferred, in which like numerals represent similar parts throughout the several views of the drawings, it being understood, however, that the invention is not limited to the specific methods and instrumentalities disclosed.

[0047] FIG. **1A** is a simple diagram of a radio-frequency (RF) lighting control system **100** comprising a dimmer switch **110** and two remote occupancy sensors **120** (e.g., passive infrared sensors). The dimmer switch **110** is adapted to be coupled in series electrical connection between an AC power source **102** and a lighting load **104** for controlling the amount of power delivered to the lighting load. The dimmer switch **110** may be adapted to be wall-mounted in a standard electrical wallbox. Alternatively, the dimmer switch **110** could be implemented as a table-top load control device. The dimmer switch **110** comprises a faceplate **112** and a bezel **113** received in an opening of the faceplate. The dimmer switch **110** further comprises a toggle actuator **114**, i.e., a button, and an intensity adjustment actuator **116**. Actuations of the toggle actuator **114** toggle, i.e., turn off and on, the lighting load **104**. Actuations of an upper portion **116A** or a lower portion **116B** of the intensity adjustment actuator **116** respectively increase or decrease the amount of power delivered to the lighting load **104** and thus increase or decrease the intensity of the lighting load **104** from a minimum intensity (e.g., 1%) to a maximum intensity (e.g., 100%). A plurality of visual indicators **118**, e.g., light-emitting diodes (LEDs), are arranged in a linear array on the left side of the bezel **113**. The visual indicators **118** are illuminated to provide feedback of the intensity of the lighting load **104**. An example of a dimmer switch having a toggle actuator **114** and an intensity adjustment actuator **116** is described in greater detail in U.S. Pat. No. 5,248,919, issued Sep. 29, 1993, entitled LIGHTING CONTROL DEVICE, the entire disclosure of which is hereby incorporated by reference.

[0048] The remote occupancy sensors **120** are removably mountable to a ceiling or a wall, for example, in the vicinity of (i.e., a space around) the lighting load **104** controlled by the dimmer switch **110**, and are operable to detect occupancy conditions in the vicinity of the lighting load. The occupancy sensors **120** may be spaced apart to detect occupancy conditions in different areas of the vicinity of the lighting load **104**. The remote occupancy sensors **120** each include an internal detector, e.g., a pyroelectric infrared (PIR) detector **310** (FIG. 3), which is housed in an enclosure **122** (e.g., an enclosed plastic housing) and will be described in greater detail below. The enclosure **122** comprises a lens **124** (e.g., an outwardly domed lens) provided in a front surface **125** of the enclosure **122** (which defines a top plate of the occupancy sensor **120**). The internal detector is operable to receive infrared energy from an occupant in the space via the lens **124** to thus sense the occupancy condition in the space. The occupancy sensors **120** are operable to process the output of the PIR detector **310** to determine whether an occupancy condition (i.e., the presence of the occupant) or a vacancy condition (i.e., the absence of the occupant) is presently occurring in the space, for example, by comparing the output of the PIR detector **310** to a predetermined occupancy voltage threshold. Alternatively, the internal detector could comprise an ultrasonic detector, a microwave detector, or any combination of PIR detectors, ultrasonic detectors, and microwave detectors.

[0049] FIG. 1B is a simplified state diagram illustrating the operation of the occupancy sensors **120** of the RF lighting control system **100**. The occupancy sensors **120** each operate in an “occupied” state or a “vacant” state in response to the detections of occupancy or vacancy conditions, respectively, in the space. If one of the occupancy sensors **120** is in the vacant state and the occupancy sensor determines that the space is occupied in response to the PIR detector **310**, the occupancy sensor changes to the occupied state.

[0050] During a setup procedure of the RF lighting control system **100**, the dimmer switch **110** may be assigned to (i.e., associated with) one or more remote occupancy sensors **120**. The remote occupancy sensors **120** transmit digital messages wirelessly via RF signals **106** to the dimmer switch **110** in response to the present state of the occupancy sensors. A message transmitted by the remote occupancy sensors **120** may include a command and identifying information, for example, a 52-bit serial number (i.e., a unique identifier) associated with the transmitting occupancy sensor. The dimmer switch **110** is responsive to messages containing the serial numbers of the remote occupancy sensors **120** to which the dimmer switch is assigned.

[0051] The commands included in the digital messages transmitted by the occupancy sensors **120** may comprise an occupied command (e.g., an occupied-take-action command or an occupied-no-action command) or a vacant command. When the lighting load **104** is off, the dimmer switch **110** is operable to turn on the lighting load in response to receiving a first occupied-take-action command from any one of the occupancy sensors **120**. The dimmer switch **110** is operable to turn off the lighting load **104** in response to the last vacant command received from those occupancy sensors **120** from which the occupancy sensor received either occupied-take-action or occupied-no-action commands. For example, if the occupancy sensors **120** both transmit occupied-take-action commands to the dimmer switch **110**, the dimmer switch will not turn off the lighting load **104** until subsequent vacant commands are received from both of the occupancy sensors.

[0052] Each occupancy sensor **120** also comprises an ambient light detector **234** (FIG. 2B), e.g., a photocell, for detecting the level of ambient light around the occupancy sensor. The occupancy sensor **120** only measures the ambient light level when an occupancy condition is first detected. The ambient light level is compared to a predetermined ambient light level threshold. If the measured ambient light level is less than the predetermined level when an occupancy condition is first detected by one of the occupancy sensors **120**, the occupancy sensor transmits the occupied-take-action command to the dimmer switch **110**. On the other hand, if the measured ambient light level is greater than the predetermined level when an occupancy condition is first detected, the occupancy sensor **120** transmits the occupied-no-action command to the dimmer switch **110**.

Accordingly, the dimmer switch **110** does not turn on the lighting load **104** if the ambient light level in the space is sufficiently high.

[0053] While one of the occupancy sensors **120** continues to detect the occupancy condition in the space (i.e., a continued occupancy condition), the occupancy sensor regularly transmits the occupied-no-action command to the dimmer switch **110**, such that the dimmer switch knows that the occupancy sensor **120** is still in the occupied state. In response to receiving the occupied-no-action command, the dimmer switch **110** either maintains the lighting load **104** on (e.g., if an occupied-take-action command was previously received) or maintains the lighting load off.

[0054] The occupancy sensors **120** are each characterized by a predetermined occupancy sensor timeout period $T_{sub.TIMEOUT}$, which provides some delay in the adjustment of the state of the occupancy sensor, specifically, in the transition from the occupied state to the vacant state. The predetermined occupancy sensor timeout period $T_{sub.TIMEOUT}$ may be user-selectable ranging, for example, from five to thirty minutes. Each occupancy sensor **120** will not transmit a vacant command until the occupancy sensor timeout period $T_{sub.TIMEOUT}$ has expired. Each occupancy sensor **120** maintain an occupancy timer to keep track of the time that has expired since the last detected occupancy condition. The occupancy sensors **120** periodically restart the occupancy timers in response to determining an occupancy condition (as shown by “Restart Timer” in the state diagram of FIG. 1B). Accordingly, the occupancy sensors **120** do not change to the vacant state, and the lighting load **104** is not turned off, in response to brief periods of a lack of movement of the occupant in the space. If the occupancy sensor **120** fails to continue detecting the occupancy conditions, the occupancy sensor **120** waits for the length of the occupancy sensor timeout period $T_{sub.TIMEOUT}$ (as shown by “Wait” in the state diagram of FIG. 1B). After the occupancy timer expires, the occupancy sensor **120** changes to the vacant state and transmits a vacant command to the dimmer switch **110** (as shown by “Timeout” in the state diagram of FIG. 1B).

[0055] If the dimmer switch **110** does not receive a digital message from any of the occupancy sensors **120** for a failsafe timeout period $T_{sub.FAILSAFE}$, the dimmer switch **110** assumes that all of the occupancy sensors are in the vacant state and turns off the lighting load **104**. To accomplish this control, the dimmer switch **110** maintains a failsafe timer. FIG. 1C is a simplified state diagram illustrating the state of the failsafe timer of the dimmer switch **110**. The failsafe timer is started when the lighting load **104** is controlled from off to one and at least one occupancy sensor **120** is assigned to the dimmer switch **110**. If there are not any occupancy sensors **120** assigned to the dimmer switch **110** when the lighting load **104** is turned on, the failsafe timer is not started. The failsafe timer is reset to the value of the failsafe timeout period $T_{sub.FAILSAFE}$ in response to receiving a digital message from any of the occupancy sensors **120** assigned to the dimmer switch **110** or in response to actuations of any the dimmer actuators (which do not cause the lighting load **104** to be turned off). When the failsafe timer expires, the dimmer switch **110** assumes that all of the occupancy sensors are in the vacant state and turns off the lighting load **104**. The failsafe timer is stopped whenever the lighting load **104** is turned off (i.e., when vacant commands are received from all occupancy sensors **120**, when one of the dimmer actuators is actuated to turn off the lighting load, or when the failsafe timer expires).

[0056] The dimmer switch **110** controls the lighting load **104** in response to the received digital messages as well as actuations of the dimmer actuators (i.e., toggle actuator **114** and the intensity adjustment actuator **116**) and the failsafe timer. FIG. 1D is a simplified state diagram illustrating how the dimmer switch **110** controls the state of the lighting load **104** (i.e., between on and off). The dimmer switch **110** does not control the intensity of the lighting load **104** in response to the occupied-no-action commands. The dimmer switch **110** turns on the lighting load **104** when the first occupied-take-action command is received or when one of the dimmer actuators is actuated to turn on the lighting load. Further, the dimmer switch **110** turns off the lighting load **104** when the last vacant command is received from the occupancy sensors **120**, when one of the dimmer actuators is actuated to turn off the lighting load, or when the failsafe timer expires.

[0057] FIG. 2A is a simplified block diagram of the dimmer switch **110**. The dimmer switch **110** comprises a controllably conductive device **210** coupled in series electrical connection between the AC power source **102** and the lighting load **104** for control of the power delivered to the lighting load. The controllably conductive device **210** may comprise any suitable type of bidirectional semiconductor switch, such as, for example, a triac, a field-effect transistor (FET) in a rectifier bridge, or two FETs in anti-series connection. The controllably conductive device **210** includes a control input coupled to a drive circuit **212**. The input to the control input will render the controllably conductive device **210** conductive or non-conductive, which in turn controls the power supplied to the lighting load **104**.

[0058] The drive circuit **212** provides control inputs to the controllably conductive device **210** in response to command signals from a controller **214**. The controller **214** is preferably implemented as a microcontroller, but may be any suitable processing device, such as a programmable logic device (PLD), a microprocessor, or an application specific integrated circuit (ASIC). The controller **214** receives inputs from the toggle actuator **114** and the intensity adjustment actuator **116** and controls the status indicators **118**. The controller **214** is also coupled to a memory **216** for storage of the preset intensity of lighting load **104** and the serial number of the occupancy sensor **120** to which the dimmer switch **110** is assigned. The memory **216** may be implemented as an external integrated circuit (IC) or as an internal circuit of the controller **214**. A power supply **218** generates a direct-current (DC) voltage $V_{sub.CC}$ for powering the controller **214**, the memory **216**, and other low-voltage circuitry of the dimmer switch **110**.

[0059] A zero-crossing detector **220** determines the zero-crossings of the input AC waveform from the AC power supply **102**. A zero-crossing is defined as the time at which the AC supply voltage transitions from positive to negative polarity, or from negative to positive polarity, at the beginning of each half-cycle. The zero-crossing information is provided as an input to controller **214**. The controller **214** provides the control inputs to the drive circuit **212** to operate the controllably conductive device **210** (i.e., to provide voltage from the AC power supply **102** to the lighting load **104**) at predetermined times relative to the zero-crossing points of the AC waveform.

[0060] The dimmer switch **110** further comprises an RF receiver **222** and an antenna **224** for receiving the RF signals **106** from the occupancy sensor **120**. The controller **214** is operable to control the controllably conductive device **210** in response to the messages received via the RF signals **106**. Examples of the antenna **224** for wall-mounted dimmer switches, such as the dimmer switch **110**, are described in greater detail in U.S. Pat. No. 5,982,103, issued Nov. 9, 1999, and U.S. patent application Ser. No. 10/873,033, filed Jun. 21, 2006, both entitled COMPACT RADIO FREQUENCY TRANSMITTING AND RECEIVING ANTENNA AND CONTROL DEVICE EMPLOYING SAME. The entire disclosures of both are hereby incorporated by reference.

[0061] FIG. 2B is a simplified block diagram of one of the remote occupancy sensors **120**. The remote occupancy sensor **120** comprises a controller **230** and an occupancy detector circuit **232**, which provides the controller with an occupancy control signal $V_{sub.OCC}$ representative of whether the space is occupied or not. The controller **230** receives an ambient light level control signal $V_{sub.AMB}$ representative of the level of ambient light around the occupancy sensor from the ambient light detector **234**. A plurality of actuators **236** provide user inputs to the occupancy sensor **120** for use during configuration and installation of the lighting control system **100** as will be described in greater detail below. The controller **230** is operable to illuminate a plurality of visual indicators **238**, e.g., light-emitting diodes (LEDs), to provide feedback to the user during configuration and installation of the occupancy sensor **120**.

[0062] According to a first embodiment of the present invention, the occupancy sensors **120** are each operable to store in a memory **240** the values of the various operating characteristics of the lighting control system **100**, e.g., the occupancy voltage threshold, the ambient light level threshold, and the occupancy sensor timeout period $T_{sub.TIMEOUT}$. The memory **240** may be implemented as an external integrated circuit (IC) or as an internal circuit of the controller **230**. To

adjust the values of the operating characteristics, the user must access the occupancy sensor **120** to actuate the actuators **236**. The occupancy sensors **120** use the operating characteristics to change between the occupied state and the vacant state as will be described in greater detail below. The occupancy sensors **120** also store the serial number in the memory **240**. The serial number may be programmed into the memory **240**, for example, during manufacture of the occupancy sensor **120**. [0063] The remote occupancy sensor **120** further comprises an RF transmitter **242** coupled to the controller **230** and an antenna **244**. In response to determining an occupancy or a vacancy condition of the space, the controller **230** causes the RF transmitter **242** to transmit a digital message to the dimmer switch **110** via the RF signals **106**. Each transmitted message comprises the serial number of the remote occupancy sensor **120** and the appropriate command dependent upon the various operating characteristics of the occupancy sensor and the magnitudes of the occupancy control signal V.sub.OCC and the ambient light level control signal V.sub.AMB. Alternatively, the RF transmitter **242** of the occupancy sensors **120** and the RF receiver **222** of the dimmer switch **110** could both comprise RF transceivers to allow for two-way communication between the occupancy sensors and the dimmer switch.

[0064] The occupancy sensor **120** also comprises two batteries: a first battery V1 and a second battery V2. The first battery V1 provides a first battery voltage V.sub.CC1 referenced to a first circuit common, and the second battery V2 provides a second battery voltage V.sub.CC2 referenced to a second circuit common. For example, the magnitudes of the first and second battery voltages V.sub.CC1, V.sub.CC2 may be the same, e.g., approximately 3 volts. The second battery V2 powers only the occupancy detector circuit **232**, while the first battery V1 powers the controller **230**, the RF transmitter **242**, and the other circuitry of the occupancy sensor **120**. Since the occupancy detector circuit **232** is powered by a separate battery from the other circuitry, the occupancy detector circuit is isolated from the noisy circuitry (e.g., the controller **230** and the RF transmitter **242**) of the occupancy sensor **120** without excessive electronic filtering. Accordingly, the amount of noise present in the occupancy detector circuit **232** is dramatically reduced without the use of advanced filters.

[0065] The magnitude of the current drawn by the occupancy detector circuit **232** is approximately equal to the magnitude of the total current drawn by the other circuitry of the occupancy sensor **120**. For example, the magnitude of the average current drawn from each of the batteries V1, V2 is less than approximately 7 μ A. The controller **230** is operable to monitor the magnitude of the first battery voltage V.sub.CC1 of the first battery V1 and to transmit a digital message representative of a low-battery condition to the dimmer switch **110** when the magnitude of the first battery voltage V.sub.CC1 drops below a predetermined level. In response to receiving the low-battery digital message, the dimmer switch **110** may, for example, blink one or more of the visual indicators **118** to indicate that the batteries V1, V2 are low. Since magnitudes of the currents drawn from the batteries V1, V2 are approximately the same, the dimmer switch **110** assumes that the magnitudes of the first and second battery voltages V.sub.CC1, V.sub.CC2 are decreasing in a similar fashion.

[0066] FIG. 3 is a simplified circuit diagram of the occupancy detector circuit **232**. The occupancy detector circuit **232** includes the PIR detector **310**, which may comprise, for example, part number LHi1128 manufactured by PerkinElmer, Inc. The PIR detector **310** receives power from the second battery V2 via a low-pass filter comprising a resistor R312 and a capacitor C314, which operate to minimize the noise introduced to the occupancy detector circuit **232** from the second battery V2. For example, the resistor R312 may have a resistance of 22 Ω , and the capacitor C314 may have a capacitance of 0.01 μ F. The PIR detector **310** generates an output signal characterized by a low frequency (e.g., approximately 0.3 Hz to 8 Hz) and representative of the change in infrared energy detected by the PIR detector **310**. These changes in infrared energy are typically representative of the occupant moving in the space.

[0067] The output of the PIR detector **310** is pulled down towards the second circuit common by a resistor R315 (e.g., having a resistance of 1 M Ω) and is coupled to a four-stage amplifier circuit via

a capacitor C316 (e.g., having a capacitance of 1 μ F) and a resistor R318 (e.g., having a resistance of 10 k Ω). The first stage of the amplifier circuit comprises an operational amplifier (OP amp) U320 and has a gain of approximately 70. A non-inverting input of the OP amp U320 is coupled to the second circuit common via a capacitor C322 (e.g., having a capacitance of 0.01 μ F). Two resistors R324, R325 are connected in series between the second battery voltage V.sub.CC2 and the second circuit common and both have, for example, resistances of 1 M Ω . The non-inverting input of the OP amp U320 is coupled to the junction of the resistors R324, R325 via a resistor R326 (e.g., having a resistance of 1 M Ω). The series-combination of a resistor R328 (e.g., having a resistance of 14.3 k Ω) and a capacitor C330 (e.g., having a capacitance of 100 μ F) is coupled between the inverting input of the OP amp U320 and the second circuit common. A capacitor C332 is coupled in parallel with the capacitor C330 and has, for example, a capacitance of 0.1 μ F. The parallel-combination of a resistor R334 and a capacitor C335 is coupled between the inverting input and the output of the OP amp U320.

[0068] The output of the OP amp U320 is coupled to the non-inverting input of a second OP amp U336 via two resistors R338, R340 (e.g., having resistances of 118 k Ω and 845 k Ω , respectively). The inverting input of the second OP amp U 336 is coupled to the output of the OP amp, such that the second OP amp operates as a buffer (i.e., forming the second stage of the amplifier circuit). The non-inverting input is coupled to the second circuit common through a capacitor C 342 (e.g., having a capacitance of 0.01 μ F). The junction of the two resistors R338, R340 is coupled to the output of the OP amp U336 via a capacitor C344 (e.g., having a capacitance of 0.047 μ F).

[0069] The third and fourth stages of the amplifier circuit of the occupancy detector circuit 232 are similar to the first and second stages, respectively. The third stage comprises a third OP amp U320' and also has a gain of approximately 70. The output of the second OP amp U336 is connected to the non-inverting input of the third OP amp U320' via a resistor R346 (e.g., having a resistance of 1 M Ω).

[0070] The fourth stage comprises a fourth OP amp U336', which also operates as a buffer. Thus, the total gain of the occupancy detector circuit 232 is approximately 4900. The output of the fourth OP amp U336' is used to generate the occupancy control signal V.sub.OCC, which is provided to an occupancy control signal input (e.g., an analog input) of the controller 230. Two resistors R350, R352 are connected in series between the second battery voltage V.sub.CC2 and the second circuit common and both have, for example, resistances of 1 M Ω . A capacitor C354 is coupled between the output of the fourth OP amp U320' and the junction of the two resistors R350, R352, and has, for example, a capacitance of 1 μ F. A resistor R356 is coupled between the junction of the two resistors R350, R352 and the occupancy control signal input of the controller 230 and has, for example, a resistance of 1 M Ω . The occupancy control signal input of the controller 230 is coupled to the second circuit common through a capacitor C358 (e.g., having a capacitance of 0.01 μ F). The controller 230 converts the occupancy control signal V.sub.OCC to a digital signal using, for example, an internal analog-to-digital converter (ADC). As previously mentioned, the occupancy detector circuit 232 draws a current having a magnitude of approximately 7 μ A or less from the second battery V2.

[0071] FIG. 4A is a front exploded perspective view and FIG. 4B is a rear exploded perspective view of one of the occupancy sensors 120. The occupancy sensor 120 comprises a base portion 412 and a flat, circular mounting plate 450 (i.e., a bottom plate), which is releasably attached to the base portion. The enclosure 122 comprises an integral cylindrical wall 415 extending from the periphery of the front surface 125, such that the wall forms a shallow, plastic cup and defines a generally, flat disk-shaped volume. The mounting plate 450 is disposed in a plane parallel to the plate of the front surface 125 of the enclosure 122 and has a diameter less than the diameter of the front surface. The front surface 125 of the enclosure 122 has a diameter greater than about 3 inches and the occupancy sensor 120 has a height from the front surface to the mounting plate 450 of less than about 1.5 inches.

[0072] The circuitry of the occupancy sensor **120** is mounted to a printed circuit board (PCB) **410**, which is connected to the base portion **412**. The base portion **412** is adapted to be connected to the housing **122** via a plurality of tabs **414** received by snaps **416** of the base portion. The PIR detector **310** is mounted to the center of the PCB **410** and is aligned with the lens **124**. When the base portion **412** is coupled to the housing **122**, the lens **124** is operable to direct the infrared energy from the space towards the PIR detector **310**.

[0073] The occupancy sensor **120** further comprises a multi-functional structure **420**, which is located between the housing **122** and base portion **412**. FIG. 4C is a perspective view of the multi-functional structure **420**. The multi-functional structure **420** comprises actuation posts **422**, **424**, **426**, which protrude through openings **428** in the front surface **125** of the occupancy sensor **120** to allow for actuation of tactile switches **430** on the PCB **410** from the front surface. The actuation posts **422**, **424**, **426** comprise a portion of the plurality of actuators **236** of the occupancy sensor **120** and are used during configuration of the lighting control system **100** to verify the operation of the occupancy sensor and the lighting control system. The multi-functional structure **420** also comprises a light pipe **432** positioned parallel to the third actuation post **426** for conducting light from one of the visual indicators **238** (i.e., one of the LEDs) mounted on the PCB **410** to the front surface **125** of the occupancy sensor **120**.

[0074] The batteries **V1**, **V2** are housed in battery compartments **434** of the base portion **412**. FIG. 4D is a rear perspective view of the base portion with the batteries **V1**, **V2** removed. When installed in the battery compartments **434**, the batteries **V1**, **V2** are electrically connected to the circuitry of the occupancy sensor **120** via electrical contacts **436** and are supported by battery supports **438** of the multi-functional structure **420**. The multi-functional structure **420** further comprises battery-removal tabs **440** that aid in removing the batteries **V1**, **V2** from the battery compartments **434**. When the tabs **440** are pulled away from the base portion **412**, flexible arms **442** of the multi-functional structure **420** flex, such that the battery supports **438** force the batteries **V1**, **V2** out of the battery compartments **434**.

[0075] As shown in FIGS. 4A and 4B, the mounting plate **450** forms a circular disk and allows the occupancy sensor **120** to be mounted to a ceiling or wall. The mounting plate **450** is first attached to the ceiling or wall via screws (not shown) received through attachment openings **452** of the mounting plate **450** and into anchors (not shown) in the ceiling or wall. The base portion **412** (along with the housing **122**) is then rotated clockwise around the perimeter of the mounting plate **450**, such that flanges **454** of the base portion **412** are received by attachment slots **456** of the support plate. The mounting plate **450** permits the mounting of the occupancy sensor **120** to selected positions within the space to produce optimal operation of the occupancy sensor.

[0076] The remainder of the plurality of actuators **236** of the occupancy sensor **120** are provided on the rear surface of the base portion **412** (as shown in FIGS. 4B and 4D) and comprise an assign button **460**, an unassign button **462**, an occupancy detection criteria (ODC) button **464**, an ambient light threshold (ALT) button **466**, and an occupancy sensor timeout period (OSTP) button **468**. Each of the buttons **460**, **462**, **464**, **466**, **468** is formed as an integral part of the base portion **412** and comprises an actuation knob at the end of a flexible arm provided in an elongated U-shaped slot. The actuation knob of each button **460**, **462**, **464**, **466**, **468** may be depressed, thus flexing the flexible arm of the button, such that the actuation knob actuates a tactile switch (not shown) mounted to the bottom side of the PCB **410**.

[0077] During configuration of the lighting control system **100**, the user may simultaneously press and hold the toggle button **114** of the dimmer switch **110** and the assign button **460** of one of the occupancy sensors **120** to link the dimmer switch and the one of the occupancy sensors. The user may also simultaneously press and hold the toggle button **114** of the dimmer switch **110** and the unassign button **462** of the occupancy sensor **120** to unassign the occupancy sensor from the dimmer switch. The lighting control system **100** may comprise a plurality of occupancy sensors **120** that may all be assigned to one dimmer switch **110**, such that the dimmer switch is responsive

to each of the occupancy sensors. The user simply needs to repeat the assignment procedure for each of the plurality of occupancy sensors **120**.

[0078] The occupancy detection criteria button **464**, the ambient light threshold button **466**, and the occupancy sensor timeout period button **468** allow for adjustment of various characteristics of the occupancy sensor **120**. Consecutive actuations of the occupancy detection criteria button **464** cause the controller **230** to adjust an occupancy detection criteria, used to determine whether the space is occupied, between a number of values, i.e., settings (e.g., three values). For example, actuations of the occupancy detection criteria button **464** may cause the controller **230** to adjust the predetermined occupancy voltage threshold to which the magnitude of the occupancy control signal V.sub.OCC is compared between a minimum value, a middle value, and a maximum value.

Alternatively, actuations of the occupancy detection criteria button **464** may cause the controller **230** to adjust a gain applied to the occupancy control signal V.sub.OCC before the magnitude of the occupancy control signal V.sub.OCC is compared to the occupancy voltage threshold. Similarly, the ambient light threshold button **466** and the occupancy sensor timeout period button **468** allow the user to adjust the values of the ambient light threshold and the occupancy sensor timeout period T.sub.TIMEOUT, respectively. A portion of the visual indicators **238** are mounted to the bottom side of the PCB **410** and shine through openings **470** in the base portion **412**. The visual indicators **238** mounted to the bottom side of the PCB **410** are illuminated by the controller **230** to distinguish which of the values of the occupancy detection criteria, the ambient light threshold and the occupancy sensor timeout period T.sub.TIMEOUT are selected.

[0079] FIG. 5 is a flowchart of a rear actuator procedure **500** executed by the controller **230** of each occupancy sensor **120** when one of the actuators **460**, **462**, **464**, **466**, **486** on the rear surface of the base portion **412** is pressed at step **510**. First, the serial number of the occupancy sensor **120** is retrieved from the memory **240** at step **512**, such that the serial number can be transmitted in a digital message to the dimmer switch **110**. If the assign button **460** is pressed at step **514**, an assign message (including the serial number) is transmitted to the dimmer switch **110** at step **516** and the rear actuator procedure **500** exits. Similarly, if the unassign button **462** is pressed at step **518**, an unassign message (including the serial number) is transmitted to the dimmer switch **110** at step **520**, before the rear actuator procedure **500** exits.

[0080] If neither the assign button **460** nor the unassign button **462** is being pressed at steps **514** and **518**, the controller **230** determines whether the occupancy detection criteria button **464**, the ambient light threshold button **466**, or the occupancy sensor timeout period button **468** is being pressed. Specifically, if the occupancy detection criteria button **464** is pressed at step **522**, the controller **230** selects the next of the three selectable values for the occupancy detection criteria at step **524**. At step **526**, the controller **230** illuminates the next of the three visual indicators **238** (that are linearly arranged next to the occupancy detection criteria button **464** as shown in FIG. 4D). The controller **230** then stores the new value of the occupancy detection criteria in the memory **240** at step **528**. If the ambient light threshold button **466** is pressed at step **530**, the controller **230** selects the next value for the ambient light threshold at step **532**, illuminates the next of the visual indicators **238** at step **534**, and stores the new ambient light threshold value in the memory **240** at step **536**. If the occupancy sensor timeout period button **468** is pressed at step **538**, the controller **230** selects the next value for the occupancy sensor timeout period T.sub.TIMEOUT at step **540**, illuminates the next of the visual indicators **238** at step **542**, and stores the new value of the occupancy sensor timeout period T.sub.TIMEOUT in the memory **240** at step **544**.

[0081] FIGS. 6A and 6B are simplified flowcharts of a dimmer actuator procedure **600** executed by the controller **214** of the dimmer switch **110** in response to an actuation of the toggle actuator **114** or the intensity adjustment actuator **116** at step **610**. If the toggle actuator **114** is actuated at step **612**, the controller **214** initializes a button timer to zero seconds and starts the button timer increasing with respect to time at step **614**. The button timer is used to determine how long the toggle actuator **114** is pressed. If the toggle actuator **114** is still being pressed at step **616**, a

determination is made as to whether the button timer is less than a predetermined button hold time, e.g., five (5) seconds, at step **618**. The dimmer actuator procedure **600** loops until either the toggle actuator **114** is released at step **616** or the button timer has exceeded the predetermined button hold time at step **618**. If the toggle button **114** is still pressed at step **616** and the button timer is greater than the predetermined button hold time at step **618**, the controller **214** executes an assignment procedure **700**, which will be described in greater detail below with reference to FIG. 7.

[0082] During the assignment procedure **700**, the dimmer switch **110** may be assigned to one or more occupancy sensors **120**. Specifically, the controller **214** is operable to store the serial numbers of the assigned occupancy sensors **120** in the memory **216**. Thereafter, the controller **214** is responsive to digital messages received from the assigned occupancy sensors **120**. If the dimmer switch **110** is assigned to at least one occupancy sensor **120**, the controller **214** starts the failsafe timer whenever the lighting load **104** is toggled from off to on.

[0083] Referring back to FIG. 6A, if the toggle actuator **114** is released at step **616** while the button timer is less than the predetermined button hold time at step **618**, the controller **214** controls the lighting load **104** appropriately. Specifically, if the lighting load **104** is on at step **620**, the controller **214** turns the lighting load off at step **622** and stops the failsafe timer at step **624**, before the dimmer actuator procedure **600** exits. If the lighting load **104** is off at step **620**, the controller **214** turns the lighting load on at step **625**. If there is a serial number of one of the occupancy sensors **120** stored in the memory **216** at step **626**, the controller **214** starts the failsafe timer at step **628** and the dimmer actuator procedure **600** exits.

[0084] Referring to FIG. 6B, if the toggle actuator **114** is not pressed at step **612**, but the upper portion **116A** of the intensity adjustment actuator **116** is pressed at step **630**, a determination is made as to whether the lighting load **104** is off at step **632**. If the lighting load **104** is off at step **632**, the controller **214** turns the lighting load on to the minimum intensity at step **634**. If there is a serial number of an occupancy sensor **120** stored in the memory **216** at step **636**, the controller **214** starts the failsafe timer at step **638** and the dimmer actuator procedure **600** exits. If the lighting load **104** is on at step **632** and the dimmer switch **110** is not at the maximum intensity at step **640**, the controller **214** increases the lighting intensity of the lighting load **104** by a predetermined increment at step **642**. If the dimmer switch **110** is at the maximum intensity at step **640**, the controller **214** does not adjust the lighting intensity. If there is a serial number of an occupancy sensor **120** stored in the memory **216** at step **644**, the controller **214** restarts the failsafe timer at step **646** and the dimmer actuator procedure **600** exits.

[0085] If the lower portion **116B** of the intensity adjustment actuator **116** is pressed at step **648** and the lighting load **104** is off at step **650**, the dimmer actuator procedure **600** exits. If the lighting load **104** is on at step **650** and the dimmer switch **110** is not at the minimum intensity at step **652**, the controller **214** decreases the lighting intensity by a predetermined increment at step **654**. If the dimmer switch **110** is at the minimum intensity at step **652**, the controller **214** does not turn off the lighting load **104**. If there is a serial number of an occupancy sensor **120** stored in the memory **216** at step **644**, the controller **214** restarts the failsafe timer at step **646** and the dimmer actuator procedure **600** exits.

[0086] FIG. 7 is a simplified flowchart of the assignment procedure **700** executed by the controller **214** of the dimmer switch **110** if the toggle actuator **114** is pressed and held for greater than the predetermined button hold time at step **618** of the dimmer actuator procedure **600**. The assignment procedure **700** is executed as long as the toggle actuator **114** is held. At step **712**, the controller **214** first begins to cycle the visual indicators **118**, such that the visual indicators are consecutively turned on and off at a first rate. Next, the controller **214** determines if an assign message or an unassign message has been received from an occupancy sensor **120** at step **714**. The assignment procedure **700** loops until either the toggle actuator **114** is released at step **716** or either an assign message or an unassign message is received at step **714**. If the toggle actuator **114** is no longer being held at step **716**, the controller **214** stops cycling the visual indicators **118** at step **718** and the

assignment procedure **700** exits.

[0087] When an assign message or an unassign message is received at step **714** while the toggle actuator **114** is still held, the controller **214** either stores the serial number of the received message in the memory **216** or deletes the serial number from the memory. Specifically, if the received message is an assign message at step **720**, and the serial number from the received message is not already stored in the memory **216** at step **722**, the controller **214** stores the serial number in the memory at step **724**. The controller **214** then temporarily cycles the visual indicators **118** at a second rate (faster than the first rate) at step **726**. The assignment procedure **700** then loops around such that another occupancy sensor **120** may be assigned to the dimmer switch **110**. If the received message is an unassign message at step **720**, and the serial number from the received message is stored in the memory **216** at step **728**, the controller **214** deletes the serial number from the memory at step **730** and temporarily cycles the visual indicators **118** at the second rate at step **726**. [0088] FIG. **8** is a flowchart of an occupancy detection procedure **800** executed periodically, e.g., every 50 msec, by the controller **230** of each occupancy sensor **120**. As previously, the controller **230** uses the occupancy timer to provide some delay in the adjustment of the state of the occupancy sensor. Whenever the controller **230** obtains a detector reading that signifies an occupancy condition, the controller initializes the occupancy timer to the predetermined occupancy sensor timeout period $T_{sub.TIMEOUT}$ and starts the occupancy timer counting down. Therefore, the occupancy sensor **120** stays in the occupied state as long as the controller **230** receives indications of the occupancy condition from the PIR detector before the occupancy timer expires. However, when the occupancy timer expires, the controller **230** changes to the vacant state as will be described in greater detail below. The controller **230** also uses a transmission timer (or “TX” timer) to keep track of when to transmit the next occupied-no-action command while in the occupied state.

[0089] Referring to FIG. **8**, the controller **230** first reads the output of the PIR detector circuit **232** at step **810**, for example, by sampling the occupancy control signal $V_{sub.OCC}$. The controller **230** then determines if the detector reading signifies an occupancy condition in the space, for example, by comparing the magnitude of the output voltage of the PIR detector to the predetermined occupancy voltage threshold. If the detector reading does not signify an occupancy condition in the space at step **814**, the occupancy detection procedure **800** simply exits. However, if the detector reading signifies an occupancy condition at step **814** and the occupancy sensor **120** is presently in the vacant state at step **815**, the controller **230** changes to the occupied state at step **816**. At step **818**, the controller **230** initializes the occupancy timer to the predetermined occupancy sensor timeout period $T_{sub.TIMEOUT}$ and starts the occupancy timer (such that the occupancy timer decreases in value with time). Then, the controller **230** reads the output of the ambient light detector **234** at step **820**. If the value of the ambient light level is less than the predetermined ambient light level threshold at step **822**, the controller **230** transmits (TX) the occupied-take-action command at step **824**. Otherwise, the controller **230** transmits the occupied-no-action command at step **826**. After transmitting either of the digital messages at step **824** and **826**, the controller **230** initializes and starts the transmission timer counting down at step **828** before the occupancy detection procedure **800** exits.

[0090] When the occupancy detection procedure **800** is executed and the state of the occupancy sensor **120** is occupied at step **815**, the controller **230** simply initializes and starts the occupancy timer at step **830** before the occupancy detection procedure **800** exits.

[0091] FIG. **9** is a flowchart of a transmission timer procedure **900** executed by the controller **230** of each occupancy sensor **120** when the transmission timer expires at step **910** to allow the occupancy sensor to regularly transmit the occupied-no-action commands to the dimmer switch **110**. If the occupancy sensor **120** is in the occupied state at step **912**, the controller **230** transmits the occupied-no-action command to the dimmer switch **110** at step **914** and restarts the transmission timer at step **916**, before the transmission timer procedure **900** exits. If the occupancy

sensor **120** is in the vacant state at step **912** when the transmission timer expires at step **910**, the controller **230** does not transmit any digital messages and the transmission timer procedure **900** simply exits.

[0092] FIG. **10** is a flowchart of an occupancy timer procedure **1000** executed by the controller **230** of each occupancy sensor **120** when the occupancy timer expires at step **1010**, i.e., when the occupancy sensor has determined that the space is unoccupied. Specifically, the controller **230** changes to the vacant state at step **1012** and transmits the vacant command to the dimmer switch **110** at step **1014** before the occupancy timer procedure **1000** exits.

[0093] FIG. **11** is a simplified flowchart of a received message procedure **1100** (or “RX” procedure) executed by the controller **214** of the dimmer switch **110** in response to receiving a digital message from one of the occupancy sensors **120** at step **1110**. The controller **214** keeps track of the states of the occupancy sensor **120** to which the dimmer switch **110** is assigned in response to the digital messages received from the occupancy sensors. Specifically, if the controller **214** receives an occupied-take-action command or an occupied-no-action command from an occupancy sensor **120**, the controller marks the serial number of the occupancy sensor as “occupied” in the memory **216**. If the controller **214** receives a vacant message from the occupancy sensor **120**, the controller marks the serial number of the occupancy sensor as “vacant” in the memory **216**. The controller waits for a vacant command from all of the occupancy sensors to which the dimmer switch **110** is assigned before turning off the lighting load **104**. However, if the failsafe timer expires, the controller **214** marks all of the serial numbers stored in the memory **216** as vacant and turns the lighting load **104** off.

[0094] Referring to FIG. **11**, after receiving the digital message at step **1110**, the controller **214** first determines whether the serial number provided in the received digital message is stored in the memory **216** at step **1112**. If not, the controller **214** does not process the received digital message and the received message procedure **1100** exits. If the serial number of the received digital message is stored in the memory **216** at step **1112** and the received digital message is an occupied-take-action command at step **1114**, the controller **214** determines if any of the serial numbers stored in the memory **216** are marked as occupied at step **1116** to determine if the space is occupied or vacant. If there are no serial numbers marked as occupied at step **1116** (i.e., the space has just become occupied), the controller **214** controls the controllably conductive device **210** to turn on the lighting load **104** at step **1118** and starts the failsafe timer at step **1120**. The controller **214** then marks the serial number of the received digital message as occupied at step **1122** and the received message procedure **1100** exits. If there are serial numbers marked as occupied at step **1116** (i.e., the space is occupied), the controller **214** marks the serial number of the received digital message as occupied at step **1124**. If the failsafe timer is presently on at step **1126**, the controller **214** restarts the failsafe timer at step **1128**, before the received message procedure **1100** exits.

[0095] If the received digital message is an occupied-no-action command at step **1130**, the controller **214** does not adjust the amount of power delivered to the lighting load **104**. The controller **214** simply marks the serial number as occupied at step **1124** and restarts the failsafe timer at step **1128** if the failsafe timer is on at step **1126**. If the received digital message is a vacant command at step **1132**, the controller **214** marks the serial number as vacant at step **1134**. If any of the serial numbers are still marked as occupied at step **1136** (i.e., the space is still occupied), the controller **214** restarts the failsafe timer at step **1128** if the failsafe timer is on at step **1126**. However, if all of the serial numbers are marked as vacant at step **1136** (i.e., the space is now vacant), the controller **214** controls the lighting load **104** off at step **1138** and stops the failsafe timer at step **1140**, before the received message procedure **1100** exits.

[0096] FIG. **12** is a simplified flowchart of a failsafe timer procedure **1200** executed by the controller **214** of the dimmer switch **110** when the failsafe timer expires at step **1210**. The controller **214** simply marks all of the serial numbers stored in the memory **216** as vacant at step **1212** and turns off the lighting load **104** at step **1214** before the failsafe timer procedure **1200** exits.

[0097] According to a second embodiment of the present invention, the dimmer switch **110** is operable to store in the memory **216** the values of the various operating characteristics of the lighting control system **100**, e.g., the occupancy voltage threshold, the ambient light level threshold, and the occupancy sensor timeout period T.sub.TIMEOUT. The dimmer switch **110** may provide, for example, an advanced programming mode, such that the values of the operating characteristics may be adjusted in response to actuations of the toggle actuator **114** and the intensity adjustment actuator **116**. An advanced programming mode is described in greater detail in U.S. Pat. No. 7,190,125, issued Mar. 13, 2007, entitled PROGRAMMABLE WALLBOX DIMMER, the entire disclosure of which is hereby incorporated by reference. Since the user does not need to access the occupancy sensors **120** (which may be mounted to a ceiling) to adjust the operating characteristics, the use of the toggle actuator **114** and the intensity adjustment actuator **116** of the dimmer switch **110** allows for easier adjustment of the operating characteristics.

[0098] Because the dimmer switch **110** stores the values of the operating characteristics, the occupancy sensors **120** must transmit multiple digital messages to the dimmer switch **110**. For example, if the occupancy voltage threshold can be programmed to three different levels, the occupancy sensors **120** must determine occupancy in the space at all three different levels and transmit the results of all three determinations to the dimmer switch **110**. The dimmer switch **110** is then able to use the result of the detections that was determined at the occupancy voltage threshold stored in the memory **216** to change between an occupied state and a vacant state and to control the lighting load **104**. The dimmer switch **110** maintains an occupancy timer (or "occ" timer), such that the dimmer switch turns off the lighting load **104** after the occupancy timeout period T.sub.TIMEOUT.

[0099] FIG. **13** is a simplified flowchart of an occupancy detection procedure **1300** executed periodically, e.g., every 50 msec, by the controller **230** of each occupancy sensor **120** according to the second embodiment of the present invention. The controller **230** begins by sampling the output of the PIR detector circuit **232** at step **1310** and selecting the first occupancy voltage threshold at step **1312**. If the sample is greater than the first occupancy voltage threshold at step **1314**, the controller **230** stores an occupancy detection for the first occupancy voltage threshold in the memory **240** at step **1316**. Otherwise, the controller **230** stores a vacancy detection in the memory **240** at step **1318**. If the controller **230** has not determined occupancy at all of the possible values of the occupancy voltage threshold at step **1320**, the controller changes to the next occupancy voltage threshold value at step **1322** and compares the reading from step **1310** to that occupancy voltage threshold at step **1314**. When the controller **230** has determined occupancy for each of the possible values of the occupancy voltage threshold at step **1320**, the occupancy detection procedure **1300** exits.

[0100] FIG. **14** is a simplified flowchart of a transmission procedure **1400** executed periodically, e.g., every one minute, by the controller **230** of each occupancy sensor **120** according to the second embodiment of the present invention. First, the controller **230** retrieves the occupancy and vacancy detections from the memory **240** at step **1410**. If there no occupancy detections at step **1412** (i.e., there have not been any occupancy detections in the last minute), the transmission procedure **1400** simply exits. Otherwise, the controller **230** selects the first occupancy voltage threshold at step **1414**. If the occupancy sensor **120** has determined at least one occupancy detection since the last execution of the transmission procedure **1400** (i.e., in the last minute) at step **1416**, the controller **230** transmits at step **1418** a digital message that indicates an occupancy detection at the first occupancy voltage threshold. If the occupancy sensor **120** did not determine at least one occupancy detection since the last execution of the transmission procedure **1400** at step **1416**, the controller **230** transmits at step **1418** a digital message that indicates a Vacant detection at the first occupancy voltage threshold.

[0101] If the controller **230** has not transmitted the results of the detections for all of the possible occupancy voltage thresholds at step **1422**, the controller selects the next occupancy voltage

threshold at step **1424** and determines at step **1416** whether at least one occupancy detection occurred at that occupancy voltage threshold. The controller **230** then either transmits an occupancy detection at step **1418** or a vacancy detection at step **1420** for the present occupancy voltage threshold. When the controller **230** is finished transmitting all of the results of the detections for the possible occupancy voltage thresholds at step **1422**, the controller **230** reads the output of the ambient light detector **234** at step **1426** and transmits the ambient light level reading to the dimmer switch **110** at step **1428** before the transmission procedure **1400** exits.

[0102] FIG. **15** is a simplified flowchart of a received message procedure **1500** executed by the controller **214** of the dimmer switch **110** in response to receiving a digital message at step **1510**. Specifically, the dimmer switch **110** may receive a number of digital messages containing the results of the detections at the various occupancy voltage thresholds and the ambient light level reading. The controller **214** first determines if the serial number of the received digital messages is stored in the memory **216** at step **1512**. If not, the received message procedure **1500** simply exits. However, if the serial number is assigned to the dimmer switch **110** at step **1512**, the controller **214** chooses at step **1514** to use the result of the detection at the desired occupancy voltage threshold (i.e., as chosen by the user during configuration).

[0103] If the result of the detection from step **1514** is not an occupancy detection at step **1516**, the received message procedure **1500** simply exits. However, if the result of the detection is an occupancy detection at step **1516**, and the dimmer switch **110** is in the vacant state at step **1518**, the controller **214** changes to the occupied state at step **1520** and then initializes and starts the occupancy timer at step **1522**. If the ambient light level (received in the digital messages at step **1510**) is less than the ambient light level threshold stored in the memory **216** at step **1524**, the controller **214** turns on the lighting load **104** at step **1526** and the received message procedure **1500** exits. If the ambient light level is not less than the ambient light level threshold at step **1524**, then the received message procedure **1500** exits.

[0104] If the result of the detection is an occupancy detection at step **1516** and the dimmer switch **110** is in the occupied state at step **1518**, the controller **214** restarts the occupancy timer at step **1528**. If, at step **1530**, the result is the first occupancy detection for the occupancy sensor **120** from which the digital messages were received at step **1512** since the dimmer switch **110** was last in the vacant state, the controller **214** determines whether the ambient light level is less than the ambient light level threshold at step **1524** and may turn on the lighting load at step **1526**. Otherwise, the received message procedure **1500** simply exits.

[0105] FIG. **16** is a flowchart of an occupancy timer procedure **1600** executed by the controller **214** of the dimmer switch **110** when the occupancy timer expires at step **1610**. Specifically, the controller **214** changes to the vacant state at step **1612** and turns off the lighting load **104** at step **1614** before the occupancy timer procedure **1600** exits.

[0106] Alternatively, the controller **230** of the occupancy sensor **120** could compare the ambient light level reading to three different ambient light level thresholds (e.g., high, medium, and low ambient light level thresholds) and then transmit the results of the comparisons to the dimmer switch **110** in a manner similar to that described above with response to the PIR occupancy detection comparisons. The dimmer switch **110** could then control the lighting load **104** based upon the resultant ambient light level threshold comparison corresponding to the ambient light level threshold stored in the memory **216**.

[0107] FIG. **17A** is a simplified block diagram of a lighting control system **100'** having a dimmer switch **110'** according to a third embodiment of the present invention. The lighting control system **100'** may additionally comprise one or more remote controls **130**. The remote control **130** comprises a plurality of actuators: an on button **132**, an off button **134**, a raise button **136**, a lower button **138**, and a preset button **140** (for recalling a preset lighting intensity stored in the memory **216** of the dimmer switch **110'**). Alternatively, the remote control **130** could comprise a plurality of preset buttons. The remote control **130** transmits digital messages via the RF signals **106** to the

dimmer switch **110'** in response to actuations of any of the actuators. The dimmer switch **110'** is responsive to digital messages containing the serial number of the remote control **130** to which the dimmer switch is associated. The dimmer switch **110'** is operable to turn on and to turn off the lighting load **104** in response to an actuation of the on button **132** and the off button **136**, respectively. The dimmer switch **110'** is operable to control the lighting load **104** to the preset intensity in response to an actuation of the preset button **134**.

[0108] During the setup procedure of the RF load control system **100'**, the dimmer switch **110'** is associated with one or more remote controls **130**. A user simultaneously presses and holds the on button **132** on the remote control **130** and the toggle button **114** on the dimmer switch **110'** to link the remote control **130** and the dimmer switch **110'**. The user may simultaneously press and hold the off button **136** on the remote control **130** and the toggle button **114** on the dimmer switch **110'** to unassociate the remote control **130** with the dimmer switch **110'**. The configuration procedure for associating the remote control **130** with the dimmer switch **110'** is described in greater detail in co-pending commonly-assigned U.S. patent application Ser. No. 11/559,166, filed Nov. 13, 2006, entitled RADIO-FREQUENCY LIGHTING CONTROL SYSTEM, the entire disclosure of which is hereby incorporated by reference.

[0109] FIG. **17B** is a simplified state diagram illustrating how the dimmer switch **110'** of the lighting control system **100'** controls the state of the lighting load **104** (i.e., between on and off). The dimmer switch **110'** turns on the lighting load **104** when the first occupied-take-action command is received from one of the occupancy sensors **120**, when one of the dimmer actuator buttons (i.e., the toggle actuator **114** and the intensity adjustment actuator **116**) is actuated to turn on the lighting load, or when digital messages are received from the remote control **130**, i.e. when one of the remote control actuators (e.g., the on button **132**, the raise button **136**, or the preset button **140** of the remote control) is actuated to turn on the lighting load **104**. Further, the dimmer switch **110** turns off the lighting load **104** when the last vacant command is received from the occupancy sensors **120**, when one of the dimmer actuator buttons is actuated to turn off the lighting load **104**, when the failsafe timer expires, or when digital messages are received from the remote control **130**, i.e. when one of the remote control actuators (e.g., the off button **134** of the remote control) is actuated to turn off the lighting load.

[0110] FIG. **17C** is a simplified state diagram illustrating the state of the failsafe timer of the dimmer switch **110'**, which is similar to the state diagram of the failsafe timer as shown in FIG. **1C** according to the first embodiment of the present invention. However, the dimmer switch **110'** of the lighting control system **100'** additionally starts the failsafe timer when digital messages to turn on the lighting load **104** are received from the remote control **130** and at least one occupancy sensor **120** is assigned to the dimmer switch **110'**. The dimmer switch **110'** restarts the failsafe timer when digital messages are received from any of the occupancy sensors **120** or remote controls **130** to which the dimmer switch is assigned. The dimmer switch **110'** is also operable to stop the failsafe timer in response to receiving digital messages to turn off the lighting load **104** from the remote control **130**.

[0111] FIG. **18** is a simplified schematic diagram of an occupancy detector circuit **232'** according to a fourth embodiment of the present invention. The occupancy detector circuit **232'** comprises a two-stage amplifier circuit having two amplifier stages and no buffer stages. Resistors **R324'**, **R325'**, **R350'**, **R352'** have, for example, resistances of 1.5 M Ω . The occupancy detector circuit **232'** has a gain of approximately 4900 and draws a current having a magnitude of approximately 5 μ A or less from the second battery **V2**.

[0112] The present invention has been described with reference to the lighting control system **100** having a plurality of occupancy sensors **120** (i.e., the dimmer switch **100** is operable to both turn on and turn off the lighting load **104** in response to the occupancy sensors). However, the concepts of the present invention can also be applied to a lighting control system having a plurality of vacancy sensors in which the dimmer switch **110** would not turn on, but would only turn off, the lighting

load **104** in response to the vacancy sensors. To implement this control with the lighting control system described in the flowcharts of FIGS. **5-12**, the dimmer switch **110** could simply not turn on the lighting load **104** and not start the failsafe timer in response to receiving an occupied-take-action command (i.e., skip steps **1118** and **1120** of the received message procedure **1100** of FIG. **11**). Alternatively, the vacancy sensors could simply transmit occupied-no-action commands rather than the occupied-take-action commands (at step **824** of the occupancy detection procedure **800** of FIG. **8**). In both cases, the dimmer switch **100** would only turn on the lighting load **100** in response to a manual actuation of the toggle actuator **114** or the intensity adjustment actuator **116**, using the dimmer actuator procedure **600** of FIGS. **6A** and **6B**.

[0113] While the present invention has been described with reference to the dimmer switch **110** for controlling the intensity of the lighting load **104**, the concepts of the present invention could be applied to load control systems comprising other types of load control devices, such as, for example, fan-speed controls for fan motors, electronic dimming ballasts for fluorescent loads, and drivers for light-emitting diodes (LEDs). Further, the concepts of the present invention could be used to control other types of electrical loads, such as, for example, fan motors or motorized window treatments.

[0114] Although the present invention has been described in relation to particular embodiments thereof, many other variations and modifications and other uses will become apparent to those skilled in the art. It is preferred, therefore, that the present invention be limited not by the specific disclosure herein, but only by the appended claims.

Claims

1. A sensing apparatus, comprising: occupant detection circuitry; ambient light detection circuitry; interface circuitry; and control circuitry to: receive a first signal indicative of a presence of an occupant in a space from the occupant detection circuitry; receive a second signal indicative of an ambient light level from the ambient light detection circuitry; responsive to receipt of the first signal: compare the second signal to an ambient light threshold value; determine whether the second signal indicates an ambient light level above a threshold; responsive to the determination that the ambient light level is at or above the threshold: generate a first output signal indicative of the occupied/high light condition; and communicate the first output signal via the interface circuitry; and responsive to the determination that the ambient light level is below the threshold: generate a second output signal indicative of an occupied/low light condition; and transmit the second output signal via the interface circuitry.
2. The sensing apparatus of claim 1 wherein the control circuitry to further, responsive to communication of the second signal: initialize a countdown timer; during a pendency of a countdown timer timeout period, re-initialize the countdown timer responsive to generation of the second signal; and responsive to expiration of the countdown timer timeout period, communicate a third output signal via the interface circuitry.
3. The sensing apparatus of claim 2, further comprising: a first manually actuatable element to provide a first actuator signal to the control circuitry wherein, responsive to receipt of the first actuator signal, the control circuitry to: incrementally cycle through a plurality of defined countdown timer timeout periods; and cause a storage of a selected countdown timer timeout period in the memory circuitry.
4. The sensing apparatus of claim 1, further comprising: memory circuitry to store at least one of: an occupancy detection voltage threshold value; or an ambient light threshold value.
5. The sensing apparatus of claim 4, further comprising: a second manually actuatable element to provide a second actuator signal to the control circuitry wherein, responsive to receipt of the second actuator signal, the control circuitry to: incrementally cycle through a plurality of defined ambient light threshold values; and cause a storage of a selected ambient light threshold value in the

memory circuitry.

6. The sensing apparatus of claim 5, further comprising: a third manually actuatable element to provide a third actuator signal to the control circuitry wherein, responsive to receipt of the third actuator signal, the control circuitry to: incrementally cycle through a plurality of defined occupancy detection voltage threshold values; and cause a storage of a selected occupancy detection voltage threshold value in the memory circuitry.

7. The sensing apparatus of claim 4, further comprising: a fourth manually actuatable element to provide a fourth actuator signal to the control circuitry; wherein, responsive to receipt of the fourth actuator signal, the control circuitry to communicate a unique identifier assigned to the occupancy sensing apparatus via the interface circuitry.

8. The sensing apparatus of claim 1 wherein the control circuitry to further, responsive to the first signal that indicates the presence of the occupant in the space: cause an activation of the ambient light detection circuitry; and cause the ambient light detection circuitry to: measure the ambient light level in the space; and generate the second signal indicative of the ambient light level in the space.

9. The sensing apparatus of claim 1, further comprising: a first energy storage device to provide power to the occupancy detection circuitry; and a second energy storage device to provide power to the ambient light detection circuitry, the memory circuitry, the interface circuitry, and the control circuitry.

10. A detection method, comprising: receiving by control circuitry, a first signal indicative of a presence of an occupant in a space from occupant detection circuitry; receiving by the control circuitry, a second signal indicative of an ambient light level from ambient light detection circuitry; responsive to the receipt of the first signal: comparing by the control circuitry, the second signal to an ambient light threshold value; determining by the control circuitry, whether the second signal indicates an ambient light level above a threshold; responsive to the determination that the ambient light level is at or above the threshold: generating by the control circuitry, a first output signal indicative of the occupied/high light condition; and causing by the control circuitry, a communication of the first output signal via communicatively coupled interface circuitry; and responsive to the determination that the ambient light level is below the threshold: generating by the control circuitry, a second output signal indicative of the occupied/low light condition; and causing by the control circuitry, a communication of the second output signal via the interface circuitry.

11. The method of claim 10 further comprising, responsive to communication of the second signal: initializing by the control circuitry, a countdown timer; re-initializing by the control circuitry, the countdown timer responsive to generation of the second signal during a pendency of a countdown timer timeout period; and causing by the control circuitry, a communication of a third output signal via the interface circuitry responsive to expiration of the countdown timer timeout period.

12. The method of claim 11, further comprising: receiving, by the control circuitry, a first actuator input signal from a first manually actuatable element; and responsive to receipt of the first actuator input signal by the control circuitry: incrementally cycling through a plurality of defined countdown timer timeout periods; and causing by the control circuitry, a storage of a selected countdown timer timeout period in the memory circuitry.

13. The method of claim 10, further comprising at least one of: causing by the control circuitry, a storage of an occupancy detection voltage threshold value in communicatively coupled memory circuitry; or causing by the control circuitry, a storage of an ambient light threshold value in the communicatively coupled memory circuitry.

14. The method of claim 13, further comprising: receiving, by the control circuitry, a second actuator input signal from a second manually actuatable element; and responsive to receipt of the second actuator signal by the control circuitry: incrementally cycling through a plurality of defined ambient light threshold values; and causing by the control circuitry, a storage of a selected ambient

light threshold value in the memory circuitry.

15. The method of claim 14, further comprising: receiving, by the control circuitry, a third actuator input signal from a third manually actuatable element; and responsive to receipt of the third actuator signal by the control circuitry: incrementally cycling through a plurality of defined occupancy detection voltage threshold values; and causing by the control circuitry, a selected occupancy detection voltage threshold value in the memory circuitry.

16. The method of claim 15, further comprising: receiving, by the control circuitry, a fourth actuator input signal from a fourth manually actuatable element; and responsive to receipt of the fourth actuator signal by the control circuitry: causing a communication of a unique identifier assigned to the occupancy sensing apparatus via the interface circuitry.

17. The method of claim 1, further comprising: responsive to the of the first signal that indicates the presence of the occupant in the space: causing, by the control circuitry, an activation of the ambient light detection circuitry; and causing, by the control circuitry, the ambient light detection circuitry to: measure the ambient light level in the space; and generate the second signal indicative of the ambient light level in the space.

18. A non-transitory, machine-readable, storage device that includes instructions that, when executed by control circuitry disposed in a detection apparatus, cause the control circuitry to: receive a first signal indicative of a presence of an occupant in a space from occupant detection circuitry; receive a second signal indicative of the ambient light level from ambient light detection circuitry; responsive to the receipt of the first signal: compare the second signal to an ambient light threshold value; determine whether the second signal indicates an ambient light level above a threshold; responsive to the determination that the ambient light level is at or above the threshold: generate a first output signal indicative of the occupied/high light condition; and cause a communication of the first output signal via communicatively coupled interface circuitry; and responsive to the determination that the ambient light level is below the threshold: generate a second output signal indicative of the occupied/low light condition; and cause communication of the second output signal via the interface circuitry.

19. The non-transitory, machine-readable, storage device of claim 18 wherein the instructions, when executed by the control circuitry, further cause the control circuitry to: responsive to communication of the second signal: initialize a countdown timer; re-initialize the countdown timer responsive to generation of the second signal during a pendency of a countdown timer timeout period; and cause a communication of a third output signal via the interface circuitry responsive to expiration of the countdown timer timeout period.

20. The non-transitory, machine-readable, storage device of claim 19 wherein the instructions, when executed by the control circuitry, further cause the control circuitry to: receive a first actuator signal from a first manually actuatable element; and responsive to receipt of the first actuator signal: incrementally cycle through a plurality of defined countdown timer timeout periods; and cause a storage of a selected countdown timer timeout period in the memory circuitry.

21. The non-transitory, machine-readable, storage device of claim 18, wherein the instruction, when executed by the control circuitry, cause the control circuitry to, at least one of: cause a storage of an occupancy detection voltage threshold value in communicatively coupled memory circuitry; or cause a storage of an ambient light threshold value in the communicatively coupled memory circuitry.

22. The non-transitory, machine-readable, storage device of claim 21 wherein the instructions, when executed by the control circuitry, further cause the control circuitry to: receive a second actuator signal from a second manually actuatable element; and responsive to receipt of the second actuator signal: incrementally cycle through a plurality of defined ambient light threshold values; and cause a storage of a selected ambient light threshold value in the memory circuitry.

23. The non-transitory, machine-readable, storage device of claim 22 wherein the instructions, when executed by the control circuitry, further cause the control circuitry to: receive a third

actuator signal from a third manually actuatable element; and responsive to receipt of the third actuator signal: incrementally cycle through a plurality of defined occupancy detection voltage threshold values; and cause a selected occupancy detection voltage threshold value in the memory circuitry.

24. The non-transitory, machine-readable, storage device of claim 23 wherein the instructions, when executed by the control circuitry, further cause the control circuitry to: receive a fourth actuator signal from a fourth manually actuatable element; and responsive to receipt of the fourth actuator signal: cause a communication of a unique identifier assigned to the occupancy sensing apparatus via the interface circuitry.

25. The non-transitory, machine-readable, storage device of claim 18, wherein the instructions, when executed by the control circuitry, further cause the control circuitry to: responsive to the of the first signal that indicates the presence of the occupant in the space: cause an activation of the ambient light detection circuitry; and cause the ambient light detection circuitry to: measure the ambient light level in the space; and generate the second signal indicative of the ambient light level in the space.
