METHOD OF FORMING HIGH VOLTAGE TRANSISTOR AND STRUCTURE RESULTING THEREFROM

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application is a divisional application of U.S. application Ser. No. 17/824,942, filed on May 26, 2022, which disclosure is incorporated by reference in their entirety.

BACKGROUND

[0002] High-voltage transistors are widely used in modern semiconductor devices, e.g., power management integrated circuits (PMIC). The high-voltage transistors are generally designed to be operated at a greater voltage, e.g., voltage greater than 10 volts, 20 volts or 30 volts. Therefore, a high breakdown voltage is required for a high-voltage transistor, which may be manufactured under a design specification different than that of a medium-voltage or low-voltage transistor in the same circuit. As such, there is a need to improve the manufacturing process of the high-voltage transistor to enhance the breakdown voltage while maintaining manufacturing compatibility with the medium-voltage or low-voltage transistors formed using the existing manufacturing processes.

BRIEF DESCRIPTION OF THE DRAWINGS

[0003] Aspects of the present disclosure are best understood from the following detailed description when read with the accompanying figures. It should be noted that, in accordance with the standard practice in the industry, various features are not drawn to scale. In fact, the dimensions of the various features may be arbitrarily increased or reduced for clarity of discussion.

[0004] FIGS. 1A to 1P are cross-sectional views of intermediate stages of a method of forming a semiconductor device, in accordance with some embodiments of the present disclosure.

DETAILED DESCRIPTION

[0005] The following disclosure provides many different embodiments, or examples, for implementing different features of the provided subject matter. Specific examples of components and arrangements are described below to simplify the present disclosure. These are, of course, merely examples and are not intended to be limiting. For example, the formation of a first feature over or on a second feature in the description that follows may include embodiments in which the first and second features are formed in direct contact, and may also include embodiments in which additional features may be formed between the first and second features, such that the first and second features may not be in direct contact. In addition, the present disclosure may repeat reference numerals and/or letters in the various examples. This repetition is for the purpose of simplicity and clarity and does not in itself dictate a relationship between the various embodiments and/or configurations discussed.

[0006] Further, spatially relative terms, such as “beneath,” “below,” “lower,” “above,” “upper” and the like, may be used herein for ease of description to describe one element or feature’s relationship to another element(s) or feature(s) as illustrated in the figures. The spatially relative terms are

intended to encompass different orientations of the device in use or operation in addition to the orientation depicted in the figures. The apparatus may be otherwise oriented (rotated 90 degrees or at other orientations) and the spatially relative descriptors used herein may likewise be interpreted accordingly.

[0007] Notwithstanding that the numerical ranges and parameters setting forth the broad scope of the disclosure are approximations, the numerical values set forth in the specific examples are reported as precisely as possible. Any numerical value, however, inherently contains certain errors necessarily resulting from the deviation normally found in the respective testing measurements. Also, as used herein, the terms “about,” “substantial” or “substantially” generally mean within 10%, 5%, 1% or 0.5% of a given value or range. Alternatively, the terms “about,” “substantial” or “substantially” mean within an acceptable standard error of the mean when considered by one of ordinary skill in the art. Other than in the operating/working examples, or unless otherwise expressly specified, all of the numerical ranges, amounts, values and percentages such as those for quantities of materials, durations of times, temperatures, operating conditions, ratios of amounts, and the likes thereof disclosed herein should be understood as modified in all instances by the terms “about,” “substantial” or “substantially.” Accordingly, unless indicated to the contrary, the numerical parameters set forth in the present disclosure and attached claims are approximations that can vary as desired. At the very least, each numerical parameter should at least be construed in light of the number of reported significant digits and by applying ordinary rounding techniques. Ranges can be expressed herein as being from one endpoint to another endpoint or between two endpoints. All ranges disclosed herein are inclusive of the endpoints, unless specified otherwise.

[0008] Embodiments of the present disclosure discuss a method of forming high-voltage (HV) transistors and a semiconductor structure resulting therefrom. The HV transistors are generally operated under a relatively high voltage, e.g., about 30 volts or higher. Among the various HV transistor configurations, laterally diffused metal-oxide semiconductor (LDMOS) transistors provide the advantages of low turn-on resistance and high breakdown voltage. However, as the voltage operation range is continually increased for the HV transistors in modern applications, the breakdown voltage of the HV transistor should also be increased accordingly for withstanding the high operation voltage. Since the existing LDMOS transistor is formed in which a uniform formation process is applied for all isolation regions of the LDMOS transistor and the isolation regions for other medium-voltage (MV) and low-voltage (LV) transistors. As a result, the isolation region designed for withstanding the high voltage may fail the design requirement despite that other isolation regions design for MV or LV transistors can still function normally.

[0009] To address the above issues, the present disclosure proposes a forming method of a semiconductor structure including the HV transistor and non-HV (NHV) transistor, where the various isolation regions subjected to different working voltages are formed with different methods and structures. As a result, the performance of the HV transistors can be improved due to the enhanced voltage-withstanding capability of the isolation region in the HV transistor while the manufacturing compatibility with the NHV transistors

can be maintained. Therefore, the overall semiconductor production cost and time can be enhanced.

[0010] FIGS. 1A to 1P are cross-sectional views of intermediate stages of a method of forming a semiconductor device **100**, in accordance with some embodiments of the present disclosure. In some embodiments, the semiconductor device **100** includes at least two zones **100A** and **100B** for forming transistors of different operation voltages. The transistors of the semiconductor device **100** may include metal-oxide semiconductor (MOS) field-effect transistors (FET). In some embodiments, the zone **100A** is referred to herein as a HV zone, and includes HV transistors, e.g., an example HV transistor **100T**. In some embodiments, the zone **100B** is referred to herein as a NHV zone, e.g., one or more of the MV zone or LV zone, and includes MV transistors or LV transistors, e.g., an example NHV transistor **100N** (shown in FIG. 1H). Throughout the present disclosure, the term “HV transistor” refers to a transistor, e.g., an LDMOS transistor, that operates in a relatively high voltage range, e.g., the voltage may be greater than 5 volts, 10 volts, 20 volts, 30 volts or higher, and terms “NHV transistor” refers to an MV or LV transistor that operates in a medium or low operation voltage range, e.g., the operation voltage may be lower than 5 volts. In some embodiments, the operation voltage ranges for the various types of transistors, e.g., the HV transistor, the MV transistor, and the LV transistor, are varying based on different applications. In some embodiments, the operation voltage of the HV transistor is no less than that of the NHV transistor, and the operation voltage of the MV transistor is no less than that of the LV transistor. The category of the three types of transistors as discussed above is shown for illustration purposes. The semiconductor device **100** can include more than two zones for accommodating more than two types of transistors of the respective operation voltage ranges.

[0011] Referring to FIG. 1A, a substrate **102** is provided or formed. In some embodiments, the substrate **102** includes semiconductor material such as bulk silicon. In some embodiments, the substrate **102** includes other semiconductor materials, such as silicon germanium, silicon carbide, gallium arsenide, or the like. In some embodiments, the substrate **102** is a p-type semiconductive substrate (acceptor type) or an n-type semiconductive substrate (donor type). Alternatively, the substrate **102** includes another elementary semiconductor, such as germanium; a compound semiconductor including gallium arsenic, gallium phosphide, indium phosphide, indium arsenide, or indium antimonide; an alloy semiconductor including SiGe, GaAsP, AlInAs, AlGaAs, GaInAs, GaInP, or GaInAsP; or combinations thereof. In yet another embodiment, the substrate **102** includes portions to form a semiconductor-on-insulator (SOI) substrate. In other alternatives, the substrate **102** may include a doped epitaxial layer, a gradient semiconductor layer, and/or a semiconductor layer overlying another semiconductor layer of a different type, such as a silicon layer on a silicon germanium layer.

[0012] A barrier layer **104** is formed in the substrate **102**. The barrier layer **104** is formed in a lower portion at a depth of the substrate **102**, wherein barrier layer and the higher portion of the substrate **102** over the barrier layer **104** are spared for the HV transistor **100T**. The barrier layer **104** is also referred to as a buried layer. Furthermore, the barrier layer **104** is configured as an isolation layer such that noise resulting from different circuits disposed in other areas (not

shown) may be shielded by the barrier layer **104**. Thus, the electrical performance of the HV transistor **100T** may be maintained. In an embodiment, the barrier layer **104** is doped with a different conductivity type than the semiconductor substrate **102**. For example, the barrier layer **104** is doped with an N-type dopant in a P-type semiconductor substrate **102**. In some embodiments, the barrier layer **104** is present only in the HV zone **100A** for the HV transistors. In some embodiments, the NHV zone **100B** that not used for the HV transistors are free of any of barrier layers.

[0013] In some embodiments, the barrier layer **104** is formed by an ion implantation operation. The implantation dose and power are dependent upon the predetermined thickness and depth of the barrier layer **104**. In some embodiments, a patterned mask layer (not separately shown) is formed over the substrate **102** to expose the HV zone **100A** while covering the other zones, e.g., NHV zone **100B**. The dopants, e.g., an N-type dopant such as arsenic, phosphorus, or the like, are implanted into substrate **102** in the region of the HV zone **100A**. In some embodiments, after the ion implantation operation is completed, the pattern mask layer is stripped or removed.

[0014] Referring to FIG. 1B, a plurality of trenches **106T** are etched in the substrate **102**. The trenches **106T** are formed on the upper surface of the substrate **102** in the HV zone **100A**. The trenches **106T** may have substantially equal depths **D1** measured from the upper surface of the substrate **102**. In some embodiments, the depth **D1** is in a range between about 0.1 μm and about 0.5 μm , e.g., 0.3 μm . The trenches **106T** may be formed using a dry etch, a wet etch, a reactive ion etch (RIE), a combination thereof, of the like. In embodiments where the trenches **106T** are formed by a dry etch, each of the trenches **106T** has substantially straight and slanted sidewalls and a substantially flat bottom surface.

[0015] In some embodiments, a plurality of trenches **206T** are also etched on the substrate **102**. The trenches **206T** are formed on the upper surface of the substrate **102** in the NHV zone **100B**. The trenches **206T** may be formed using a dry etch, a wet etch, an RIE, a combination thereof, of the like. The trenches **206T** may have substantially equal depths **D1** measured from the upper surface of the substrate **102**, and may have depths **D1** equal to those of the trenches **106T**. In some embodiments, each of the trenches **206T** has substantially straight and slanted sidewalls and a substantially flat bottom surface. In some embodiments, the trenches **106T** and **206T** are formed by a same etching operation; alternatively, the trench **106T** and the trench **206T** are formed in separate etching operations.

[0016] Referring to FIG. 1C, a plurality of isolation regions **106** are formed in the trenches **106T**. The isolation regions **106** may include electrically insulating materials or dielectric materials, such as silicon oxide; however, other dielectric materials, e.g., silicon nitride, silicon oxynitride, silicon carbide, or the like, are also possible for forming the isolation regions **106**. In some embodiments, the isolation regions **106** are formed using chemical vapor deposition (CVD), physical vapor deposition (PVD), atomic layer deposition (ALD), oxidation, nitridation, spin-on coating, or other suitable deposition methods. In some embodiments, the isolation regions **106** are referred to as shallow trench isolation (STI) regions.

[0017] After the dielectric material of the isolation region **106** fills the trench **106T**, a planarization operation, e.g., chemical mechanical polishing (CMP), may be adopted to

remove excess dielectric materials over the upper surface of the substrate **102** and level the surface of the isolation regions **106** with the upper surface of the substrate **102**.

[0018] In some embodiments, a plurality of isolation regions **206** are formed in the trenches **206T**. The isolation regions **206** may include electrically insulating materials or dielectric materials, such as silicon oxide; however, other dielectric materials, e.g., silicon nitride, silicon oxynitride, silicon carbide, or the like, are also possible for forming the isolation regions **206**. The isolation regions **206** may have a material the same as or different from the isolation region **106**. In some embodiments, the isolation regions **206** are formed using CVD, PVD, ALD, oxidation, nitridation, spin-on coating, or other suitable deposition methods. After the dielectric material of the isolation region **206** fills the trench **206T**, a planarization operation, e.g., CMP, may be adopted to remove excess dielectric materials over the upper surface of the substrate **102** and level the surface of the isolation regions **206** with the upper surface of the substrate **102**. In some embodiments, the isolation regions **206** are formed together with the forming of the isolation regions **106**. In some embodiments, the isolation regions **206** are referred to as STI regions.

[0019] As discussed previously, in some embodiments, the electrically insulating material, e.g., silicon dioxide, of the isolation regions **106**, **206** are formed by deposition, e.g., reacting silicon-based precursor with oxygen in a deposition chamber to generate a film of silicon oxide on the sidewalls and bottom of the trench **106T** or **206T**. The silicon atoms of the substrate **102** around the trenches **106T** or **206T** are substantially not involved in the formation of the isolation region **106** or **206**.

[0020] In some embodiments, the isolation regions **106**, **206** are formed in the NHV zone **100B** and at the boundary of the HV zone **100A** and the NHV zone **100B**, and are used to define the boundary of the zones **100A**, **100B** or the boundary of each transistor in the respective zones **100A**, **100B**. The isolation regions **106**, **206** are also configured to electrically isolate adjacent transistors.

[0021] Referring to FIG. 1C, a sacrificial layer **108** is formed on the upper surface of the substrate **102** across the zones **100A** and **100B**. The sacrificial layer **108** may be formed of a dielectric material, such as silicon oxide, silicon nitride, silicon oxynitride, or other suitable materials. In the present embodiment, the sacrificial layer **108** is formed of silicon oxide. The sacrificial layer **108** can serve as a protective layer to protect the surface of the substrate **108** from being damaged in subsequent operations, and can be removed subsequent to these operations. In some embodiments, the sacrificial layer **108** is formed on the surface of the substrate **102** in the area other than the isolation regions **106**, **206**. As a result, the isolation regions **106**, **206** are exposed through the sacrificial layer **108**. In some embodiments, the sacrificial layer **108** is formed by CVD, PVD, ALD, thermal oxidation, or other suitable deposition methods.

[0022] Referring to FIG. 1D, a patterned mask layer **110** is formed over the substrate **102**. In some embodiments, the patterned mask layer **110** covers the isolation regions **106**, **206** and the sacrificial layer **108**. The patterned mask layer **110** may be formed of photoresist materials, or other hard mask material, e.g., oxide or nitride. As an example process of forming the patterned mask layer **110**, a photoresist or hard mask material is deposited over the substrate **102**, e.g.,

using CVD, PVD, ALD, spin-on coating, or other suitable deposition methods. The photoresist or hard mask material is patterned to form an opening **110T** in the HV zone **100A**. The forming of the opening **110T** may include lithography and etching operations. The etching operation may include a dry etch, a wet etch, an ion reactive etch (RIE), or a combination thereof. The opening **110T** is used to define the area of an implant region **109** of the HV transistor **100T**, in which the area has a width **W2** from a cross-sectional view. In some embodiments, the width **W2** is in a range between about 0.1 μm and about 10 μm , e.g., 3 μm . Through the forming of the opening **110T**, a portion of the sacrificial layer **108** is exposed through the patterned mask layer **110**.

[0023] Referring to FIG. 1E, an ion implantation operation **111** is performed to form an implant region **109** in the HV zone **100A**. Through the ion implantation operation **111**, oxygen ions are implanted into the depths of the substrate **102** through the opening **110T** and the upper portions of the sacrificial layer **108**. The oxygen ions are brought to contact and bond with the silicon atoms of the substrate **102** to convert the substrate **102** into silicon dioxide in the implant region **109**. As such, the implant region **109** is also referred to herein an isolation region. The depth and profile of the implant region **109** are controlled by the recipes of the implantation operation **111**. For example, the implantation operation **111** adopts an implant energy between about 100 KeV and about 300 KeV. The implantation operation **111** may use the process gas, such as oxygen, with an implant dose in a range between about 1×10^{15} and about 1×10^{18} atoms/cm². In some embodiments, the process gas further includes fluorine for expediting the formation of the silicon oxide through enhancing the bonding of oxygen ions with silicon in the substrate **102**. The fluorine ions may not be left in the implant region **109** after the implantation operation **111**. In some embodiments, the implant dose of the fluorine is in a range between about 1×10^{15} and about 1×10^{18} atoms/cm². A flow rate ratio of fluorine to oxygen may be in a range between about 5% and about 70%.

[0024] In some embodiments, the implantation operation **111** includes one or more implantations to control the profile and boundary of the implant region **109**. For example, in order to obtain a desired height or depth **D2** of the isolation region **112**, the implantation operation **111** adopts with different implantation energies or implant doses to introduce the oxygen dopants to different depths of the substrate **102** in different shots of the implantations **111** to thereby achieve a uniformly distributed implant region **109**. In some embodiments, the implant region **109** include a rectangular shape from a cross-sectional view. In some embodiments, the implant region **109** has substantially straight sidewalls **109S** and a substantially flat bottom surface **109B**. The implant region **109** may has a height or depth **D2**. In some embodiments, the depth **D2** is greater than the depth **D1** for providing higher voltage-withstanding capability during a HV operation condition. In some embodiments, the depth **D2** is in a range between about 0.3 μm and about 4 μm , between about 0.5 μm and about 2.5 μm , e.g., 1.5 μm . In some embodiments, a depth ratio of **D3** to **D1** is between about 1.2 and about 20, or between about 1.5 and about 8. The implant region **109** may have bottom corners **109C** formed by the sidewall **109S** and the bottom surface **109B**. In some embodiments, the bottom corner **109C** is an angled corner. The bottom corner **109C** has a right angle. The independently determined depths **D2** for the implant region

109 can provide design flexibility for the HV transistor **100T** and would not be limited to the uniform depth **D1** of the isolation regions **106**, **206** in the other regions.

[0025] FIG. 1F illustrates the removal of the patterned mask layer **110**. In some embodiments, the patterned mask layer **110** is removed or stripped off using an etching operation. In some embodiments, the sacrificial layer **108** is retained and exposed after the removal of the patterned mask layer **110**.

[0026] In some embodiments, a thermal operation **114** is performed on the substrate **102** after the isolation region **106** or **206** is formed. As a result, the thermal operation **114** may aid in densify the isolation regions **106**, **206**. In some embodiments, the thermal operation **114** activates the implanted oxygen ions and drives them to diffuse beyond the implant region **109** to thereby form an expanded isolation region **112**. The thermal operation **114** may be performed using rapid thermal anneal (RTA), laser anneal, or other suitable annealing operations. In some embodiments, the thermal operation **114** is performed at a temperature between about 1000° C. and about 1200° C., e.g., between about 1050° C. and about 1100° C., for a period between about 30 seconds and about 30 minutes. In some embodiments, the CMP operation performed on the isolation regions **106**, **206** is performed after the thermal operation **114**. In some embodiments, since the isolation region **112** is formed by deposition, no excess material of the silicon oxide in the isolation region **112** extends over the surface of the substrate **102** or needs to be removed. In some embodiments, the isolation region **112** is referred to as an STI region.

[0027] In some embodiments, the isolation region **112** is formed as including fluorine-doped silicon oxide. In some embodiments, fluorine atoms are driven out of the isolation region **112** after the thermal operation **114**, and therefore the doping concentration of fluorine is decreased in the isolation region **112**. In some embodiments, the isolation region **112** is free of fluorine after the thermal operation **114**.

[0028] As shown in FIG. 1F, the isolation region **112** has a width **W3** and a depth (or height) **D3**. For the convenience of comparison, the boundary of the implant region **109** is marked in FIG. 1F by a dotted box within the isolation region **112**. Since the isolation region **112** is expanded from the implant region **109**, the sidewall **112S** is moved outward laterally from the sidewall **109S**, and the bottom surface **112B** is moved downward from the bottom surface **109B**.

[0029] In some embodiments, the bottom surface **112B** of the isolation region **112** is spaced apart from the barrier layer **104** by a distance **D4**. The distance **D4** may be in a range between about 0.05 μm and about 4 μm , e.g., 0.5 μm . The HV transistor may include a channel region **C1** formed between the isolation region **112** and the barrier layer **104** such that carriers may drift between source/drain terminals through the channel region **C1**. The height of the channel region **C1** may have impact on the channel resistance. Therefore, the dimensions of the depth **D3** and the distance **D4** should be appropriately determined to seek balance between the increased breakdown voltage and the reduced channel resistance.

[0030] In some embodiments, each of the isolation regions **106** or **206** has a bottom corner **106C** at the bottom of the isolation region **106** or **206**. The bottom corner **106C** has a shape formed by the sidewall **106S** and the bottom surface **106B**. Referring to FIGS. 1B and 1E, since the shape of the bottom corner **106C** is formed by etching the trench **106T**

through an etching operation, e.g., a dry etch, the sidewall **106S** or the bottom surface **106B** is substantially straight from a cross-sectional view. In some embodiments, the bottom corner **106C** is an angled corner.

[0031] In contrast, the isolation region **112** has a bottom corner **112C** at the bottom of the isolation region **112**. The bottom corner **112** has a shape formed by the sidewall **112S** and the bottom surface **112B**. Referring to FIG. 1E, since the shape of the bottom corner **106C** is determined by the implanted and then thermally diffused oxygen ions which react with silicon atoms of the substrate **102** to form a region of silicon oxide, the diffused oxygen ions lead to the rounded or curved contour of the sidewall **106S** or the bottom surface **106B** around the bottom corner **112C** from a cross-sectional view. As a result, in some embodiments, the bottom corner **106C** or **206C** is sharper than the bottom corner **112C**. In some embodiments, the bottom corner **112C** is a rounded corner.

[0032] Since the bottom corner **112C** is connected to the sidewall **112S** and the bottom surface **112B**, the sidewall **112S** and the bottom surface **112B** may not be entirely flat or straight. In some embodiments, the sidewall **112S** has an upper portion proximal to the surface of the substrate **102** and a lower portion connected to the bottom corner **112C**, in which the upper portion is substantially straight. The upper portion of the sidewall **112S** has a height **D3F** less than the height **D3**. In some embodiments, a height ratio between the upper portion (with height **D3F**) and the sidewall **112S** (with height **D3**) is in a range between about 20% and about 80%. In some embodiments, the bottom surface **112B** has a central portion and edge portions on two sides of the central portion, in which the central portion is substantially straight or flat. The central portion of the bottom surface **112B** has a width **W3F** less than the width **W3**. In some embodiments, a width ratio between the central portion (with width **W3F**) and the bottom surface **112B** (with width **W3**) is in a range between about 20% and about 80%. In some embodiments, the lower portion of the sidewall **112S** and the edge portions of the bottom surface **112B** constitute the bottom corner **112C**, in which the lower portion of the sidewall **112S** and the edge portions of the bottom surface **112B** are curved or rounded from a cross-sectional view.

[0033] The proposed isolation region **112** provides advantages. During HV operation of the HV transistors in the zone **100A**, a great amount of charges tend to accumulate at the tip or angled corner of the isolation region **112** if the isolation region **112** is formed otherwise to include angle corners. Existing methods of forming the isolation region **112** may not provide a rounded corner **112C** as illustrated in FIG. 1E. Rather, in some embodiments, the isolation region **112** is formed along with the forming of the isolation region **106** or **206** during a single formation operation, e.g., an etching operation to generate a trench with angled corners, followed by filling the trench by dielectric materials. As a result, the electric field caused by the HV transistor may have peaks around the angled corner of the isolation region **112**, and the performance of the HV transistor may be adversely affected. In contrast, the rounded corner **112C** of the isolation region **112** proposed herein can effectively eliminate the angles on the sidewall **112S** or the bottom surface **112B** to thereby reduce the likelihood of electric field peaks around the corner **112C**.

[0034] In some embodiments, through the usage of the patterned mask layer **108**, the isolation region **112** has

sidewalls substantially perpendicular to the surface of the substrate **102**. In some embodiments, the isolation region **106** (or **206**) has a sidewall **106S** and a bottom surface **106B**, where the sidewall **106S** forms an included angle **A1** with the bottom surface **106B**. An extension line of the upper portion of the sidewall **112S** and an extension line of the central portion of the bottom surface **112B** form an included angle **A2**. In some embodiments, the included angle **A1** is an obtuse angle. In some embodiments, the included angle **A2** is substantially a right angle. The included angle **A1** is greater than the included angle **A2**.

[0035] Subsequently, several doped regions are formed in the zones **100A** and **100B**. Referring to FIG. 1G, a well region **116** is formed in the HV zone **100A**. The well region **116** may include a dopant of a conductivity type, e.g., P-type, different from the barrier layer **104**. The well region **116** may be a doped region formed by an ion implantation operation with an implant dose between about 10^{16} atoms/cm² and about 10^{17} atoms/cm². The well region **116** may be used to form a guard ring to prevent or mitigate leakage current.

[0036] Doped regions **212**, **222** and **232** are formed in the HV zone **100A**, and a doped region **242** is formed in the NHV zone **100B**, as shown in FIG. 1H. The doped regions **212**, **222**, **232** and **242** may include dopants of a conductivity type, e.g., N-type, the same as the barrier layer **104**. The doped regions **212**, **222**, **232** and **242** may be formed as well regions by an ion implantation operation with an implant dose between about 10^{16} atoms/cm² and about 10^{17} atoms/cm². In some embodiments, the doped regions **212**, **222**, **232** and **242** are formed by separate implantation operations or the same implantation operation.

[0037] Through the formation of the doped regions **212**, **222** and **232**, doped regions **252** and **262** are defined accordingly. The doped regions **252** and **262** may also referred to as well regions, and have a conductivity type the same as the substrate **102** or the well region **116**. In some embodiments, the doped regions **212**, **222**, **232**, **242**, **252**, **262** or the well region **116** are defined by the isolation regions **106** or **206**. In some embodiments, the doped region **222** includes a channel region, which allows carriers to drift between the source/drain regions of the HV transistor **100T** along with sidewall **112S** and the bottom surface **112B** of the isolation region **112** upon appropriate bias voltages on the gate electrode and source/drain terminals of the HV transistor **100T**. The doped region **222** laterally surrounds the isolation region **112**, and therefore the channel region forms a U-shape around the sidewalls **112S** and the bottom surface **112B** in the doped region **222**.

[0038] Referring to FIG. 1I, doped regions **214** and **224** are formed in the doped regions **252** and **262**, respectively. The doped regions **214** and **224** may include dopants of a conductivity type, e.g., P-type, the same as the corresponding doped regions **252** and **262**. In some embodiments, the doped regions **214** and **224** include dopant concentrations greater than their corresponding doped regions **252** and **262**. The doped regions **214** and **224** may be formed by an ion implantation operation with an implant dose between about 10^{17} atoms/cm² and about 10^{19} atoms/cm². In some embodiments, the doped regions **214** and **224** are formed by separate implantation operations or the same implantation operation.

[0039] Referring to FIG. 1J, doped regions **216**, **226** and **236** are formed in the HV zone **100A**. The doped regions

216, **226**, **236** may include dopants of a conductivity type, e.g., N-type, the same as the barrier layer **104** or the doped regions **212**, **222**, **232**, **242**. In some embodiments, the doped regions **216**, **226**, **236** include dopant concentrations greater than their corresponding doped regions **212**, **222**, **232**. The doped regions **216**, **226**, **236** may be formed by an ion implantation operation with an implant dose between about 10^{18} atoms/cm² and about 5×10^{19} atoms/cm². In some embodiments, the doped regions **216**, **226**, **236** are formed by separate implantation operations or the same implantation operation.

[0040] FIG. 1K illustrates the formation of sacrificial gate structures **121** and **131** for the HV transistor **100T** and the NHV transistor **100N** in the HV zone **100A** and the NHV region **100B**, respectively. In some embodiments, the sacrificial layer **108** is removed. The sacrificial layer is removed by an etching operation, e.g., a dry etch, a wet etch, an RIE, a combination thereof, or the like. The surface of the substrate **102** is exposed accordingly.

[0041] The sacrificial gate structure **121** or **131** may include a gate dielectric layer **118** or **128** deposited in the HV zone **100A** and the NHV region **100B**, respectively. In some embodiments, the gate dielectric layers **118** and **218** are formed of dielectric materials, e.g., nitride, oxide, oxynitride, or the like. In an embodiment, the gate dielectric layers **118** and **128** include a high-k material, such as HfO₂, ZrO₂, La₂O₃, Y₂O₃, Al₂O₃, TiO₂, HfSi_xO₃, ZrSi_xO₃, LaSi_xO₃, YSi_xO₃, AlSi_xO₃, TiSi_xO₃, or the like. The gate dielectric layers **118** and **128** may include the same or different materials.

[0042] In some embodiments, the sacrificial gate structure **131** or **133** also includes a sacrificial gate layer **103** or **113** over the gate dielectric layer **118** or **128**, respectively. The sacrificial gate layer **103** or **113** may include a gate electrode formed of a conductive material, e.g., polysilicon. In some embodiments, the sacrificial gate layer **103** or **113** includes a multilayer structure, e.g., a hard mask is formed over the gate electrode. The sacrificial gate layer **103** or **113** may be formed by photolithography and etching operations. The etching operation may include a dry etch, a wet etch, an RIE, or a combination thereof. The sacrificial gate layer **103** in the HV zone **100A** may be disposed over the isolation region **112**. The sacrificial gate layer **103** may partially cover or overlap the isolation region **112** and partially cover or overlap the doped region **214**. In some embodiments, the sacrificial gate layer **103** extends from a location above the doped region **252** to a location above the isolation region **112** through the doped region **222**. In some embodiments, the sacrificial gate layer **103** is formed between two adjacent isolation regions **206** in the NHV region **100B**.

[0043] Referring to FIG. 1K, gate spacers **122** or **132** are formed on sidewalls of the respective sacrificial gate structure **131** or **133**. In an embodiment, the gate spacers **122** or **132** are formed of a dielectric material such as oxide, oxynitride, nitride, nitrogen-bearing oxide, nitrogen-doped oxide, silicon oxynitride or high-k materials. The gate spacers **122** or **132** may include a multilayer structure. The gate spacers **122** or **132** may be formed by depositing a blanket dielectric material covering the sacrificial gate layer **103** and **113** and the surface of the substrate **102**, followed by an anisotropic etching operation to remove the horizontal portions of the dielectric material.

[0044] Referring to FIG. 1L, two doped regions **246** are formed in the NHV zone **100B**. The doped regions **246** may

include dopants of a conductivity type, e.g., N-type or P-type. In some embodiments, the doped regions **246** include dopant concentrations greater than the corresponding doped region **242**. The doped regions **246** may be formed by an ion implantation operation with an implant dose between about 10^{18} atoms/cm² and about 5×10^{19} atoms/cm². In some embodiments, the doped region **246** are formed by an implantation operations using the sacrificial gate structure **131** and the gate spacers **132** as an implant mask.

[0045] Referring to FIG. 1M, doped regions **218**, **228**, **238**, **248** are formed in the respective doped regions **212**, **226**, **236** and **246** with the same conductivity type, e.g., N-type. Similarly, doped regions **268** and **278** are formed in the respective doped regions **224** and **214** with the same conductivity type, e.g., P-type. In addition, a doped region **258** is formed in the doped region **214** adjacent to the doped region **278**, in which the doped region **258** has a conductivity type different from that of the doped region **278**. The doped regions **218**, **228**, **238**, **248**, **258**, **268** and **278** may be formed to reduce contact resistance of the corresponding doped regions. In some embodiments, the doped regions **218**, **228**, **238**, **248**, **268** and **278** include dopant concentrations greater than their corresponding doped regions **216**, **226**, **236**, **246**, **224** and **214**. The doped regions **218**, **228**, **238**, **248**, **258**, **268** and **278** may be formed by an ion implantation operation with an implant dose between about 10^{19} atoms/cm² and about 5×10^{20} atoms/cm².

[0046] In some embodiments, a butted contact **288** is formed over the doped regions **258** and **278**. In some embodiments, the butted contact **288** electrically connect the doped regions **258** and **278**. The butted contact **288** and include conductive materials, such as titanium, tungsten, copper, aluminum, alloys thereof, or the like.

[0047] Referring to FIG. 1N, an interlayer dielectric (ILD) layer **160** is formed over the substrate **102**. The ILD layer **160** may be formed with a variety of dielectric materials and may be, for example, oxide, oxynitride, silicon nitride, nitrogen-bearing oxide, nitrogen-doped oxide, silicon oxynitride, polymer, or the like. The ILD layer **160** may formed by any suitable method, such as CVD, PVD, spin coating, or the like. In some embodiments, a planarization operation, e.g., CMP, is adopted to remove excess dielectric materials over the upper surface of the ILD layer **160** and level the surface of the sacrificial gate structures **121**, **131** with the upper surface of the ILD layer. The sacrificial gate structures **121**, **131** or the gate spacers **122**, **132** are exposed through ILD layer **160** after the CMP operation.

[0048] Referring to FIG. 1O, the sacrificial gate structures **121**, **131** are removed and replaced by replacement gate structures **123**, **133**, respectively. The sacrificial gate layers **103**, **113** are removed and replaced by gate electrodes **125**, **135**, respectively. In some embodiments, each of the gate electrodes **125** and **135** includes a capping layer, a glue layer, a barrier layer, one or more work function adjustment layer, and a filling layer, the combinations thereof, or the like. Each of the aforesaid component layers of the replacement gate structures **123**, **133** may be formed by CVD, PVD, ALD, sputtering, or other suitable deposition methods.

[0049] In some embodiments, the gate electrode **125** in the HV zone **100A** is disposed over the isolation region **112**. The gate electrode **125** partially covers or overlaps the isolation region **112** and partially covers or overlaps the doped region **214**. In some embodiments, the gate electrode **125** extends from a location above the doped region **252** to a location

above the isolation region **112** through the doped region **222**. In some embodiments, the gate electrode **125** is formed between two adjacent isolation regions **106** in the HV region **100A**. In some embodiments, the gate electrode **135** is formed between two adjacent isolation regions **106** or doped regions **246** in the NHV region **100B**.

[0050] In some embodiments, during operation, the doped regions **246** serve as source/drain regions of the NHV transistor **100N** while the replacement gate structure **133** serves as the gate terminal of the NHV transistor **100N**. In some embodiments, the doped region **242** is used to define an active region of a NHV transistor **100N** in the NHV zone **100B**.

[0051] In some embodiments, during operation, the doped regions **214** and **226** serve as source/drain regions of the HV transistor **100T** while the replacement gate structure **123** serves as the gate terminal of the HV transistor **100T**. In some embodiments, the doped regions **252**, **262** and **116** form a first guard ring of a conductivity type opposite to the doped region **222**, in which the first guard ring laterally surround the channel region formed in the doped region **222**. In some embodiments, the doped regions **212**, **232** and the barrier layer **104** form a second guard ring of a conductivity type identical to the doped region **222**, in which the second guard ring laterally surround the first guard ring and the doped region **222**. The first guard ring and the second guard ring are formed to prevent leakage and ensure proper functioning of the HV transistor **100T**.

[0052] Referring to FIG. 1P, several conductive vias **266** are formed in the ILD layer **160**. One or more conductive vias **266** formed over the HV zone **100A** are electrically coupled to the doped regions **218**, **228**, **238**, **268** and **288**. One or more conductive vias **266** formed over the NHV zone **100B** are electrically coupled to the doped regions **248**. The conductive vias **266** may be formed by forming openings through the ILD layer **160** by an etching operation. A conductive material may fill the openings to electrically connect the underlying structures (e.g., doped regions **218**, **228**, **238**, **248**, **268** and **288**) to overlying structures (not separately shown). The conductive material of the conductive vias **266** may include, but is not limited to, titanium, tantalum, titanium nitride, tantalum nitride, copper, copper alloys, nickel, tin, gold, or combinations thereof.

[0053] According to an embodiment, a semiconductor structure includes a first zone and a second zone. The first zone includes: a first transistor on a substrate; and a first isolation region in the substrate and defining a boundary of the first transistor. The second zone includes a second transistor on the substrate, wherein the second transistor includes: a second isolation region in the substrate and a gate electrode disposed over the substrate, the gate electrode partially overlapping the second isolation region; and a barrier layer below and spaced apart from the second isolation region.

[0054] According to an embodiment, a semiconductor structure includes a first zone and a second zone. The first zone includes: a first transistor on a substrate; and a first isolation region in the substrate and defining a boundary of the first transistor. The second zone includes: a second transistor on the substrate, wherein the second transistor comprises a second isolation region in the substrate and a channel region laterally surrounding the second isolation region; and a barrier layer below the second isolation region.

[0055] According to an embodiment, a semiconductor structure includes a first zone and a second zone. The first zone includes: a first transistor on a substrate; and a first isolation region in the substrate and defining a boundary of the first transistor, wherein the first isolation region has a first depth. The second zone includes: a second transistor on the substrate, wherein the second transistor comprises a second isolation region in the substrate and a gate electrode disposed over the substrate; and a barrier layer below and spaced apart from the second isolation region. The second isolation region has a second depth greater than the first depth.

[0056] The foregoing outlines features of several embodiments so that those skilled in the art may better understand the aspects of the present disclosure. Those skilled in the art should appreciate that they may readily use the present disclosure as a basis for designing or modifying other processes and structures for carrying out the same purposes and/or achieving the same advantages of the embodiments introduced herein. Those skilled in the art should also realize that such equivalent constructions do not depart from the spirit and scope of the present disclosure, and that they may make various changes, substitutions, and alterations herein without departing from the spirit and scope of the present disclosure.

What is claimed is:

1. A semiconductor structure, comprising:
 - a first zone comprising:
 - a first transistor on a substrate; and
 - a first isolation region in the substrate and defining a boundary of the first transistor; and
 - a second zone comprising:
 - a second transistor on the substrate, wherein the second transistor comprises a second isolation region in the substrate and a gate electrode disposed over the substrate, the gate electrode partially overlapping the second isolation region; and
 - a barrier layer below and spaced apart from the second isolation region.
2. The semiconductor structure according to claim 1, wherein the second transistor further comprises a channel region partially overlapping the barrier layer from a top-view perspective.
3. The semiconductor structure according to claim 2, wherein the channel region laterally surrounds the second isolation region.
4. The semiconductor structure according to claim 3, wherein the channel region extends to a region between the second isolation region and the barrier layer.
5. The semiconductor structure according to claim 2, wherein the second transistor further comprises a gate dielectric layer arranged between the channel region and the gate electrode, wherein the gate dielectric layer is non-overlapped with the second isolation region.
6. The semiconductor structure according to claim 1, wherein the second transistor further comprises a sidewall spacer on a side of the gate electrode, wherein the second isolation region extends beyond the sidewall spacer.
7. The semiconductor structure according to claim 1, wherein the first isolation region has a first depth, and the second isolation region has a second depth greater than the first depth.
8. The semiconductor structure according to claim 1, wherein the first isolation region has a first sidewall and a

first bottom surface, and the second isolation region has a second sidewall and a second bottom surface, wherein the first sidewall and the first bottom surface forms a first included angle, and the second sidewall and the second bottom surface forms a second included angle less than the first included angle.

9. The semiconductor structure according to claim 1, wherein the first isolation region has a first bottom corner, and the second isolation region has a second bottom corner less sharper than the first bottom corner.

10. The semiconductor structure according to claim 1, wherein the second isolation region comprises fluorine-doped silicon oxide.

11. A semiconductor structure, comprising:

a first zone comprising:

- a first transistor on a substrate; and
- a first isolation region in the substrate and defining a boundary of the first transistor; and

a second zone comprising:

- a second transistor on the substrate, wherein the second transistor comprises a second isolation region in the substrate and a channel region laterally surrounding the second isolation region; and
- a barrier layer below the second isolation region.

12. The semiconductor structure according to claim 11, wherein the first isolation region has a first depth, and the second isolation region has a second depth, wherein a ratio of the second depth to the first depth is between about 1.5 and about 8.0.

13. The semiconductor structure according to claim 11, further comprising a third isolation region in the substrate, the third isolation region defining a boundary of the second transistor and has a depth substantially equal to that of the first isolation region.

14. The semiconductor structure according to claim 11, wherein the barrier layer is an N-type layer.

15. The semiconductor structure according to claim 11, wherein the channel region is included in a first doped region with a conductivity same as that of the barrier layer.

16. The semiconductor structure according to claim 15, wherein the second transistor further comprises a second doped region and a third doped region on two sides of the second isolation region.

17. The semiconductor structure according to claim 16, wherein a concentration of the second doped region or the third doped region is greater than that of the first doped region.

18. A semiconductor structure, comprising:

a first zone comprising:

- a first transistor on a substrate; and
- a first isolation region in the substrate and defining a boundary of the first transistor, wherein the first isolation region has a first depth; and

a second zone comprising:

- a second transistor on the substrate, wherein the second transistor comprises a second isolation region in the substrate and a gate electrode disposed over the substrate; and
- a barrier layer below and spaced apart from the second isolation region, wherein the second isolation region has a second depth greater than the first depth.

19. The semiconductor structure according to claim **18**, wherein the second transistor further comprises a well region between the second isolation region and the barrier layer.

20. The semiconductor structure according to claim **19**, wherein the second transistor further comprises two source/drain regions on two sides of the second isolation region and a doped region laterally surrounding the second isolation region and one of the source/drain region.
