APPARATUS, METHOD AND COMPUTER PROGRAM

Abstract

An apparatus for a receiver is provided, said apparatus comprising means for receiving an input signal, based on a frequency domain signal, means for performing deprecoding on the received input signal and means for providing the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.

Background/Summary

FIELD

[0001] The present application relates to a method, apparatus, system and computer program and in particular but not exclusively to a deep learning receiver for a Discrete Fourier Transform (DFT)-spread-Orthogonal Frequency Division Multiplexing (OFDM) signal.

BACKGROUND

[0002] A communication system can be seen as a facility that enables communication sessions between two or more entities such as user terminals, base stations and/or other nodes by providing carriers between the various entities involved in the communications path. A communication system can be provided for example by means of a communication network and one or more compatible communication devices. The communication sessions may comprise, for example, communication of data for carrying communications such as voice, video, electronic mail (email), text message, multimedia and/or content data and so on. Non-limiting examples of services provided comprise two-way or multi-way calls, data communication or multimedia services and access to a data network system, such as the Internet.

[0003] In a wireless communication system at least a part of a communication session between at least two stations occurs over a wireless link. Examples of wireless systems comprise public land mobile networks (PLMN), satellite based communication systems and different wireless local networks, for example wireless local area networks (WLAN). Some wireless systems can be divided into cells, and are therefore often referred to as cellular systems.

[0004] A user can access the communication system by means of an appropriate communication device or terminal. A communication device of a user may be referred to as user equipment (UE) or user device. A communication device is provided with an appropriate signal receiving and transmitting apparatus for enabling communications, for example enabling access to a communication network or communications directly with other users. The communication device may access a carrier provided by a station, for example a base station of a cell, and transmit and/or receive communications on the carrier.

[0005] The communication system and associated devices typically operate in accordance with a given standard or specification which sets out what the various entities associated with the system are permitted to do and how that should be achieved. Communication protocols and/or parameters which shall be used for the connection are also typically defined. One example of a communications system is UTRAN (3G radio). Other examples of communication systems are the long-term evolution (LTE) of the Universal Mobile Telecommunications System (UMTS) radio-access technology and so-called 5G or New Radio (NR) networks. NR is being standardized by the 3rd Generation Partnership Project (3GPP).

SUMMARY

[0006] In a first aspect there is provided an apparatus for a receiver, the apparatus comprising means for receiving an input signal, based on a frequency domain signal, means for performing deprecoding on the received input signal and means for providing the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.

[0007] Means for performing deprecoding may comprise an inverse Discrete Fourier Transform, iDFT, deprecoding function.

[0008] The apparatus may comprise means for performing the deprecoding on a data branch of the input signal.

[0009] The data branch may comprise frequency-time grid symbols $N_{\text{sub},f} \times N_{\text{sub},t}$, where $N_{\text{sub},f}$ comprises the number of subcarriers and $N_{\text{sub},t}$ comprises number of orthogonal frequency-division multiplexing, OFDM, symbols.

[0010] The apparatus may comprise means for concatenating the deprecoded signal with a raw channel estimate branch of the frequency domain signal and providing the concatenated signal as

the input for the machine learning model.

[0011] The apparatus may comprise means for providing the input signal, prior to deprecoding, to a further machine learning model for processing the input signal, and means for performing deprecoding on an output of the further machine learning model.

[0012] The output of the further machine learning model may be $2 \times N_{\text{sub.f}} \times N_{\text{sub.t}}$, where $N_{\text{sub.f}}$ comprises iDFT size and $N_{\text{sub.t}}$ comprises the number of orthogonal frequency-division multiplexing, OFDM, symbols.

[0013] The output of the further machine learning model may further comprise a constellation monitoring output.

[0014] The apparatus may comprise means for causing a trigger to be sent to an apparatus for training the machine learning model and, if present, the further machine learning model and means for receiving an acknowledgment from the apparatus in response to the request.

[0015] The apparatus may comprise means for providing training configuration information to the apparatus, means for receiving training data from the apparatus in response to the configuration information and means for providing the training data to an entity for training the machine learning model and, if present, the further machine learning model.

[0016] The apparatus may comprise means for receiving deployment configuration information from a transmitter of the input signal and means for determining whether to deploy the machine learning model and, if present, the further machine learning model based on the deployment configuration information.

[0017] The deployment configuration information may comprise at least one of an indication to perform the deprecoding on the frequency domain signal, subcarrier number information, modulation and coding scheme, rank and a fallback indicator.

[0018] The apparatus may comprise means for determining not to deploy the machine learning model and, if present, the further machine learning model based on the fallback indicator.

[0019] In a second aspect there is provided a method for a receiver, the method comprising receiving an input signal, based on a frequency domain signal, performing deprecoding on the received input signal and providing the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.

[0020] Performing deprecoding may comprise an inverse Discrete Fourier Transform, iDFT, deprecoding function.

[0021] The method may comprise performing the deprecoding on a data branch of the input signal.

[0022] The data branch may comprise frequency-time grid symbols $N_{\text{sub.f}} \times N_{\text{sub.t}}$, where $N_{\text{sub.f}}$ comprises the number of subcarriers and $N_{\text{sub.t}}$ comprises number of orthogonal frequency-division multiplexing, OFDM, symbols.

[0023] The method may comprise concatenating the deprecoded signal with a raw channel estimate branch of the frequency domain signal and providing the concatenated signal as the input for the machine learning model.

[0024] The method may comprise providing the input signal, prior to deprecoding, to a further machine learning model for processing the input signal, and performing deprecoding on an output of the further machine learning model.

[0025] The output of the further machine learning model may be $2 \times N_{\text{sub.f}} \times N_{\text{sub.t}}$, where $N_{\text{sub.f}}$ comprises iDFT size and $N_{\text{sub.t}}$ comprises the number of orthogonal frequency-division multiplexing, OFDM, symbols.

[0026] The output of the further machine learning model may further comprise a constellation monitoring output.

[0027] The method may comprise causing a trigger to be sent to an apparatus for training the machine learning model and, if present, the further machine learning model and receiving an acknowledgment from the apparatus in response to the request.

[0028] The method may comprise providing training configuration information to the apparatus,

receiving training data from the apparatus in response to the configuration information and providing the training data to an entity for training the machine learning model and, if present, the further machine learning model.

[0029] The method may comprise receiving deployment configuration information from a transmitter of the input signal and determining whether to deploy the machine learning model and, if present, the further machine learning model based on the deployment configuration information.

[0030] The deployment configuration information may comprise at least one of an indication to perform the deprecoding on the frequency domain signal, subcarrier number information, modulation and coding scheme, rank and a fallback indicator.

[0031] The method may comprise determining not to deploy the machine learning model and, if present, the further machine learning model based on the fallback indicator.

[0032] In a third aspect there is provided an apparatus comprising: at least one processor and at least one memory including a computer program code, the at least one memory and computer program code configured to, with the at least one processor, cause the apparatus at least to, at a receiver, receive an input signal, based on a frequency domain signal, perform deprecoding on the received input signal and provide the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.

[0033] The apparatus may comprise an inverse Discrete Fourier Transform, iDFT, deprecoding function.

[0034] The apparatus may be caused to perform the deprecoding on a data branch of the input signal.

[0035] The data branch may comprise frequency-time grid symbols $N_{\text{sub},f} \times N_{\text{sub},t}$, where $N_{\text{sub},f}$ comprises the number of subcarriers and $N_{\text{sub},t}$ comprises number of orthogonal frequency-division multiplexing, OFDM, symbols.

[0036] The apparatus may be caused to concatenate the deprecoded signal with a raw channel estimate branch of the frequency domain signal and provide the concatenated signal as the input for the machine learning model.

[0037] The apparatus may be caused to provide the input signal, prior to deprecoding, to a further machine learning model for processing the input signal, and perform deprecoding on an output of the further machine learning model.

[0038] The output of the further machine learning model may be $2 \times N_{\text{sub},f} \times N_{\text{sub},t}$, where $N_{\text{sub},f}$ comprises iDFT size and $N_{\text{sub},t}$ comprises the number of orthogonal frequency-division multiplexing, OFDM, symbols.

[0039] The output of the further machine learning model may further comprise a constellation monitoring output.

[0040] The apparatus may be caused to cause a trigger to be sent to an apparatus for training the machine learning model and, if present, the further machine learning model and receive an acknowledgment from the apparatus in response to the request.

[0041] The apparatus may be caused to provide training configuration information to the apparatus, receive training data from the apparatus in response to the configuration information and provide the training data to an entity for training the machine learning model and, if present, the further machine learning model.

[0042] The apparatus may be caused to receive deployment configuration information from a transmitter of the input signal and determine whether to deploy the machine learning model and, if present, the further machine learning model based on the deployment configuration information.

[0043] The deployment configuration information may comprise at least one of an indication to perform the deprecoding on the frequency domain signal, subcarrier number information, modulation and coding scheme, rank and a fallback indicator.

[0044] The apparatus may be caused to determine not to deploy the machine learning model and, if present, the further machine learning model based on the fallback indicator.

[0045] In a fourth aspect there is provided a computer readable medium comprising program instructions for causing an apparatus to perform at least the following at a receiver, receiving an input signal, based on a frequency domain signal, performing deprecoding on the received input signal and providing the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.

[0046] Performing deprecoding may comprise an inverse Discrete Fourier Transform, iDFT, deprecoding function.

[0047] The apparatus may be caused to perform performing the deprecoding on a data branch of the input signal.

[0048] The data branch may comprise frequency-time grid symbols symbols $N_{\text{sub.f}} \times N_{\text{sub.t}}$, where $N_{\text{sub.f}}$ comprises the number of subcarriers and $N_{\text{sub.t}}$ comprises number of orthogonal frequency-division multiplexing, OFDM, symbols.

[0049] The apparatus may be caused to perform concatenating the deprecoded signal with a raw channel estimate branch of the frequency domain signal and providing the concatenated signal as the input for the machine learning model.

[0050] The apparatus may be caused to perform providing the input signal, prior to deprecoding, to a further machine learning model for processing the input signal, and performing deprecoding on an output of the further machine learning model.

[0051] The output of the further machine learning model may be $2 \times N_{\text{sub.f}} \times N_{\text{sub.t}}$, where $N_{\text{sub.f}}$ comprises iDFT size and $N_{\text{sub.t}}$ comprises the number of orthogonal frequency-division multiplexing, OFDM, symbols.

[0052] The output of the further machine learning model may further comprise a constellation monitoring output.

[0053] The apparatus may be caused to perform causing a trigger to be sent to an apparatus for training the machine learning model and, if present, the further machine learning model and receiving an acknowledgment from the apparatus in response to the request.

[0054] The apparatus may be caused to perform providing training configuration information to the apparatus, receiving training data from the apparatus in response to the configuration information and providing the training data to an entity for training the machine learning model and, if present, the further machine learning model.

[0055] The apparatus may be caused to perform receiving deployment configuration information from a transmitter of the input signal and determining whether to deploy the machine learning model and, if present, the further machine learning model based on the deployment configuration information.

[0056] The deployment configuration information may comprise at least one of an indication to perform the deprecoding on the frequency domain signal, subcarrier number information, modulation and coding scheme, rank and a fallback indicator.

[0057] The apparatus may be caused to perform determining not to deploy the machine learning model and, if present, the further machine learning model based on the fallback indicator.

[0058] In a fifth aspect there is provided a non-transitory computer readable medium comprising program instructions for causing an apparatus to perform at least the method according to the third or fourth aspect.

[0059] In the above, many different embodiments have been described. It should be appreciated that further embodiments may be provided by the combination of any two or more of the embodiments described above.

Description

DESCRIPTION OF FIGURES

[0060] Embodiments will now be described, by way of example only, with reference to the accompanying Figures in which:

[0061] FIG. 1 shows a schematic diagram of an example 5GS communication system;

[0062] FIG. 2 shows a schematic diagram of an example mobile communication device;

[0063] FIG. 3 shows a schematic diagram of an example control apparatus;

[0064] FIG. 4 shows a block diagram of a conventional UL receiver architecture with a potential DeepRx replacement;

[0065] FIG. 5 shows a block diagram of a DeepRx structure for an OFDM system;

[0066] FIG. 6 shows a transmitter (Tx) and receiver (Rx) signal processing chain for OFDM and DFTS-OFDM systems;

[0067] FIG. 7 shows a flowchart of a method according to an example embodiment;

[0068] FIG. 8 shows a block diagram of a structure of a predeprecoded DeepRx according to an example embodiment;

[0069] FIG. 9 shows a detailed block diagram of a structure of a predeprecoded DeepRx according to an example embodiment;

[0070] FIG. 10 shows a block diagram of a structure of a deprecoded embedded hybrid DeepRx according to an example embodiment;

[0071] FIG. 11 shows a detailed block diagram of a structure of a deprecoded embedded hybrid DeepRx according to an example embodiment;

[0072] FIG. 12 shows a signalling diagram according to an example embodiment;

[0073] FIG. 13 shows a signalling diagram according to an example embodiment;

[0074] FIG. 14 shows a block diagram of scheduling according to an example embodiment;

[0075] FIG. 15 shows a block diagram of scheduling according to an example embodiment;

[0076] FIG. 16 shows uncoded bit error rate (BER) for a conventional receiver and a receiver according to a first and second example embodiment;

[0077] FIG. 17 shows coded BER for a conventional receiver and a receiver according to a first and second example embodiment;

[0078] FIG. 18 shows BER in training for a conventional receiver and a receiver according to a first and second embodiment;

[0079] FIG. 19 shows a constellation output according to an example embodiment.

DETAILED DESCRIPTION

[0080] Before explaining in detail the examples, certain general principles of a wireless communication system and mobile communication devices are briefly explained with reference to FIGS. 1 to 3 to assist in understanding the technology underlying the described examples.

[0081] An example of a suitable communications system is the 5G System (5GS). Network architecture in 5GS may be similar to that of LTE-advanced. Base stations of NR systems may be known as next generation Node Bs (gNBs). Changes to the network architecture may depend on the need to support various radio technologies and finer QoS support, and some on-demand requirements for example QoS levels to support QoE of user point of view. Also network aware services and applications, and service and application aware networks may bring changes to the architecture. Those are related to Information Centric Network (ICN) and User-Centric Content Delivery Network (UC-CDN) approaches. NR may use multiple input-multiple output (MIMO) antennas, many more base stations or nodes than the LTE (a so-called small cell concept), including macro sites operating in co-operation with smaller stations and perhaps also employing a variety of radio technologies for better coverage and enhanced data rates.

[0082] 5G networks may utilise network functions virtualization (NFV) which is a network architecture concept that proposes virtualizing network node functions into “building blocks” or entities that may be operationally connected or linked together to provide services. A virtualized

network function (VNF) may comprise one or more virtual machines running computer program codes using standard or general type servers instead of customized hardware. Cloud computing or data storage may also be utilized. In radio communications this may mean node operations to be carried out, at least partly, in a server, host or node operationally coupled to a remote radio head. It is also possible that node operations will be distributed among a plurality of servers, nodes or hosts. It should also be understood that the distribution of labour between core network operations and base station operations may differ from that of the LTE or even be non-existent.

[0083] FIG. 1 shows a schematic representation of a 5G system (5GS) **100**. The 5GS may comprise a user equipment (UE) **102** (which may also be referred to as a communication device or a terminal), a 5G radio access network (5GRAN) **104**, a 5G core network (5GCN) **106**, one or more application functions (AF) **108** and one or more data networks (DN) **110**.

[0084] An example 5G core network (CN) comprises functional entities. The 5GCN **106** may comprise one or more access and mobility management functions (AMF) **112**, one or more session management functions (SMF) **114**, an authentication server function (AUSF) **116**, a unified data management (UDM) **118**, one or more user plane functions (UPF) **120**, a unified data repository (UDR) **122** and/or a network exposure function (NEF) **124**. The UPF is controlled by the SMF (Session Management Function) that receives policies from a PCF (Policy Control Function).

[0085] The CN is connected to a terminal device via the radio access network (RAN). The 5GRAN may comprise one or more gNodeB (GNB) distributed unit functions connected to one or more gNodeB (GNB) centralized unit functions. The RAN may comprise one or more access nodes.

[0086] A UPF (User Plane Function) whose role is called PSA (Protocol Data Unit (PDU) Session Anchor) may be responsible for forwarding frames back and forth between the DN (data network) and the tunnels established over the 5G towards the UE(s) exchanging traffic with the DN.

[0087] A possible mobile communication device will now be described in more detail with reference to FIG. 2 showing a schematic, partially sectioned view of a communication device **200**. Such a communication device is often referred to as user equipment (UE) or terminal. An appropriate mobile communication device may be provided by any device capable of sending and receiving radio signals. Non-limiting examples comprise a mobile station (MS) or mobile device such as a mobile phone or what is known as a 'smart phone', a computer provided with a wireless interface card or other wireless interface facility (e.g., USB dongle), personal data assistant (PDA) or a tablet provided with wireless communication capabilities, voice over IP (VOIP) phones, portable computers, desktop computer, image capture terminal devices such as digital cameras, gaming terminal devices, music storage and playback appliances, vehicle-mounted wireless terminal devices, wireless endpoints, mobile stations, laptop-embedded equipment (LEE), laptop-mounted equipment (LME), smart devices, wireless customer-premises equipment (CPE), or any combinations of these or the like. A mobile communication device may provide, for example, communication of data for carrying communications such as voice, electronic mail (email), text message, multimedia and so on. Users may thus be offered and provided numerous services via their communication devices. Non-limiting examples of these services comprise two-way or multi-way calls, data communication or multimedia services or simply an access to a data communications network system, such as the Internet. Users may also be provided broadcast or multicast data. Non-limiting examples of the content comprise downloads, television and radio programs, videos, advertisements, various alerts and other information.

[0088] A mobile device is typically provided with at least one data processing entity **201**, at least one memory **202** and other possible components **203** for use in software and hardware aided execution of tasks it is designed to perform, including control of access to and communications with access systems and other communication devices. The data processing, storage and other relevant control apparatus can be provided on an appropriate circuit board and/or in chipsets. This feature is denoted by reference **204**. The user may control the operation of the mobile device by means of a suitable user interface such as key pad **205**, voice commands, touch sensitive screen or

pad, combinations thereof or the like. A display **208**, a speaker and a microphone can be also provided. Furthermore, a mobile communication device may comprise appropriate connectors (either wired or wireless) to other devices and/or for connecting external accessories, for example hands-free equipment, thereto.

[0089] The mobile device **200** may receive signals over an air or radio interface **207** via appropriate apparatus for receiving and may transmit signals via appropriate apparatus for transmitting radio signals. In FIG. **2** transceiver apparatus is designated schematically by block **206**. The transceiver apparatus **206** may be provided for example by means of a radio part and associated antenna arrangement. The antenna arrangement may be arranged internally or externally to the mobile device.

[0090] FIG. **3** shows an example of a control apparatus **300** for a communication system, for example to be coupled to and/or for controlling a station of an access system, such as a RAN node, e.g. a base station, eNB or gNB, a relay node or a core network node such as an MME or S-GW or P-GW, or a core network function such as AMF/SMF, or a server or host. The method may be implemented in a single control apparatus or across more than one control apparatus. The control apparatus may be integrated with or external to a node or module of a core network or RAN. In some embodiments, base stations comprise a separate control apparatus unit or module. In other embodiments, the control apparatus can be another network element such as a radio network controller or a spectrum controller. In some embodiments, each base station may have such a control apparatus as well as a control apparatus being provided in a radio network controller. The control apparatus **300** can be arranged to provide control on communications in the service area of the system. The control apparatus **300** comprises at least one memory **301**, at least one data processing unit **302**, **303** and an input/output interface **304**. Via the interface the control apparatus can be coupled to a receiver and a transmitter of the base station. The receiver and/or the transmitter may be implemented as a radio front end or a remote radio head.

[0091] Technology known as DeepRx (deep learning receiver) aims to leverage customized AI/ML techniques to augment capacity on the physical layer (PHY). Non-negligible performance gain over conventional methods in terms of reduced transmission error under the same radio frequency (RF) channel condition has been demonstrated in studies of DeepRx based on both simulation and real-world data. Meanwhile, superiority in terms of robustness against diverse channel condition and Doppler effects has also been shown.

[0092] FIG. **4** depicts a conventional uplink (UL) receiver architecture with multiple digital signal processing (DSP) blocks **402**, including channel estimation, equalization and demodulation. DeepRx **403** may be used to replace DSP blocks, e.g., the channel estimation, equalization and demodulation blocks as illustrated in FIG. **4**. That is, de-mapped frequency-time-domain data in the user plane, together with key messages from a scheduler **401** such as modulation and coding scheme (MCS), physical resource block (PRB), and Rank in radio resource management (RRM)-plane will become the input to DeepRx **403**. The output of DeepRx **403** may be fed to a legacy decoding functional module.

[0093] FIG. **5** shows an example DeepRx structure for an orthogonal frequency-division multiplexing (OFDM) system. The structure comprise a deep convolutional neural network (CNN) **503** structured receiver designed for OFDM signal detection. DeepRx **503** takes frequency-time domain resource elements (after fast Fourier transform (FFT)) of received data and corresponding raw channel estimates as input and outputs the bit likelihood ratio (LLR) for decoding. By leveraging frequency-time domain correlations and the transmission symbols' distribution pattern, DeepRx **503** can outperform traditional receiver schemes, such as those based on conventional LMMSE receivers.

[0094] Discrete Fourier transform (DFT)-Spread OFDM (DFTS-OFDM) has been adopted to enlarge power amplifier (PA) efficiency on the device side in the uplink transmission. It is designed with coverage-challenged situations and supports flexible discrete Fourier transform (DFT) sizes in

implementation. Support for DFTS-OFDM is mandatory in the device and the network can therefore configure DFT-precoding for a particular device whenever necessary.

[0095] FIG. 6 shows a transmitter (Tx) and receiver (Rx) signal processing chain for an OFDM system and a DFTS-OFDM system. The DFTS-OFDM Tx signal processing chain includes DFT precoding and the DFTS-OFDM Rx signal processing chain includes inverse DFT (iDFT) deprecoding.

[0096] As described in 3GPP specifications, a UE determines whether or not to apply transform (DFT) precoding and the UE shall consider the transform (DFT) precoding either 'enabled' or 'disabled' according to the higher layer configured parameter.

[0097] Therefore, compatibility with a DFTS-OFDM system is a requirement for future implementations of DeepRx, especially when it is deployed in base station (BS) side.

[0098] Success of DeepRx on Single Input Single Output (SISO) or Multiple Input Multiple Output (MIMO) OFDM systems has been shown. Nevertheless, nonnegligible performance drop or difficulties in DeepRx training has been observed when it comes to single-carrier OFDM scenarios, e.g., DFTS-OFDM

[0099] In other words, current DeepRx is not compatible with the format of DFTS-OFDM, which is a mandatory feature for beyond 5G devices to support as mentioned above. Incompatibility of DeepRx to the DFTS-OFDM system may be due to the fact that the CNN structured DeepRx may not be able to learn to mimic the iDFT deprecoding operation which spans across the whole OFDM frame (shown in FIG. 6). Thus, customized system design is required to make DeepRx compatible with DFTS-OFDM waveforms.

[0100] FIG. 7 shows a flowchart of a method according to an example embodiment. The method may be performed at a receiver.

[0101] In S1, the method comprises receiving an input signal based on a frequency domain signal.

[0102] In S2, the method comprises performing deprecoding on the received input signal

[0103] In S3, the method comprises providing the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.

[0104] The frequency domain signal may be a single carrier frequency domain signal or DFTS-OFDM signal.

[0105] Signal deprecoding is the inverse operation of signal precoding. If the signal precoding were realized by means of DFT precoding then iDFT deprecoding would be the inverse operation. The deprecoding may be performed by an iDFT deprecoding function.

[0106] The method may provide two schemes to augment DeepRx's compatibility with DFTS-OFDM signal detection.

[0107] In a first example embodiment, the input signal is the frequency domain signal. The method may comprise performing the deprecoding on a data branch of the input signal. The data branch may comprise frequency-time grid symbols $N_{\text{sub.f}} \times N_{\text{sub.t}}$, where $N_{\text{sub.f}}$ comprises the number of subcarriers and $N_{\text{sub.t}}$ comprises number of orthogonal frequency-division multiplexing, OFDM, symbols. The method may comprise concatenating the deprecoded signal with a raw channel estimate branch of the frequency domain signal and providing the concatenated signal as the input for the machine learning model. In this example embodiment, the machine learning model may be referred to as DeepRx.

[0108] In a first option, where the deprecoding is performed on the frequency domain signal, a pre-executed de-precoding function block is introduced on a received data branch before being concatenated with a raw channel estimation branch, and then fed to legacy DeepRx.

[0109] FIG. 8 shows an example structure according to the first option. The inputs to DeepRx **803** remain the same as shown in FIG. 5, i.e., a data branch and a raw estimate branch, where the data branch is the frequency-time resource elements after FFT and the raw estimate branch is the raw estimated channel response based on sparse pilots. An iDFT deprecoding function **802** is introduced to be applied on the received data branch which behaves as a pre-deprecoding operation

before the data is concatenated with a lower branch (a raw channel estimates branch) and then fed to the DeepRx **803**.

[0110] FIG. **9** shows a more detailed structure of the example shown in FIG. **8**.

[0111] Taking 1T1R transmission, the input data includes Branch 1 and Branch 2 which comprise the received symbols after FFT which transforms them to the frequency-time grid symbols with the size of $N_{\text{sub.f}} \times N_{\text{sub.t}}$, where $N_{\text{sub.f}}$ refers to the number of subcarriers and $N_{\text{sub.t}}$ refers to the number of OFDM symbols in one slot (which is 14 according to 3GPP definition). Branch 1 and 2 are the real part and imaginary part of the received symbols respectively. The DMRS occupied resource elements (RE) are set to be '0'.

[0112] The input data also includes Branch 3 and 4 which comprise the raw channel estimates branches where non-demodulation reference signals (DMRS) resource elements (RE) are set to be '0'. One branch size is also $N_{\text{sub.f}} \times N_{\text{sub.t}}$. Branch 3 and 4 are also the real part and imaginary part respectively.

[0113] All the branches are concatenated before being fed to the neural network (NN) **803**.

[0114] The output data comprises bit LLRs with the dimension of $N_{\text{sub.mod}} \times N_{\text{sub.f}} \times N_{\text{sub.t}}$, where $N_{\text{sub.mod}}$ refers the number of bits per RE and depends on the modulation scheme.

[0115] In the training phase, the output will be used to compute a loss function with transmitted bits for model training. In the inference phase (application), the output will be fed to decoder.

[0116] The deprecoding is only applied to received symbols before being separated to real part and imaginary part. The deprecoding is a fixed operation following the conventional operation on frequency domain.

[0117] In the example structure shown in FIG. **9**, the NN structure **803** (also referred to as DeepRx) includes 2 convolutional layers and 11 ResNet Block in between. Any other suitable NN structures may be used.

[0118] In a second example embodiment, the method may comprise providing the input signal, prior to deprecoding, to a further machine learning model for processing the input signal and performing deprecoding on an output of the further machine learning mode. In this embodiment, the input signal is a processed frequency domain signal (i.e., the frequency domain signal which has been processed by the further machine learning model).

[0119] In this example embodiment, the machine learning model may be referred to as PostDeepRx and the further machine learning model may be referred to as DeepRx.

[0120] In the second example embodiment, a cascaded design may be provided with a DeepRx-Deprecoding-PostDeepRx structure where a function block of deprecoding is embedded between the DeepRx and PostDeepRx whose parameters are jointly learnt and optimized.

[0121] The output of the further machine learning model in this example embodiment is $2 \times N_{\text{sub.f}} \times N_{\text{sub.t}}$, where $N_{\text{sub.f}}$ comprises iDFT size and $N_{\text{sub.t}}$ comprises the number of orthogonal frequency-division multiplexing, OFDM, symbols.

[0122] The output of the further machine learning model may further comprise a constellation monitoring output.

[0123] The constellation monitoring output may be provided for further analysis. The output of iDFT deprecoding has semantic meaning if the input and output of the iDFT deprecoding block is well designed. With further expert or machine type analysis, one can learn the hardware and channel conditions, or even DeepRx itself. In other words, this is one step towards making the DeepRx receiver explainable and consequently more trustworthy.

[0124] FIG. **10** shows the general structure of an example according to the second option. The deprecoding function block **1002** is embedded between DeepRx **1003b** and PostDeepRx **1003a**. The data format of DeepRx **1003b** output and PostDeepRx **1003a** input size is designed to be $2 \times N_{\text{sub.f}} \times N_{\text{sub.t}}$ where $N_{\text{sub.f}}$ and $N_{\text{sub.t}}$ represent iDFT size and number of OFDM symbols, respectively. The dimension 2 refers to the real and imaginary part of the equalized signals.

[0125] FIG. **11** shows a more detailed structure of the general structure in FIG. **10**.

[0126] The input data in this example embodiment comprises a data branch and a raw estimate branch as described with reference to the first example embodiment. However, in this example, no pre-deprecoding is applied to the received symbols.

[0127] The output data of the machine learning model **1003a** comprises bit LLRs with the dimension of $N_{\text{sub.mod}} \times N_{\text{sub.f}} \times N_{\text{sub.t}}$ and the output of the further machine learning mode (**1003b**) comprises post equalised constellation-like pattern with the dimension of $2 \times N_{\text{sub.f}} \times N_{\text{sub.t}}$.

[0128] In the training phase, the Bit LLR output will be used to compute loss function with transmitted bits for model training. In the inference phase (application), the Bit LLR output will be fed to decoder, and the constellation-like pattern may be recorded for further analysis.

[0129] In the second example embodiment, the deprecoding function block **1002** is embedded between the NNs, which are described below.

[0130] The embedded deprecoding is a fixed operation and not learnable in back propagation. PreDeepRx and Post DeepRx may be jointly trained together.

[0131] In the second example embodiment, the DeepRx comprises two separate NNs as shown in FIG. 10.

[0132] The first NN, referred to as DeepRx NN **1003b**, includes 2 convolutional layers and 11 ResNet Blocks. The kernel number of output convolutional layer is set to be 2 with output data dimension of $2 \times N_{\text{sub.f}} \times N_{\text{sub.t}}$.

[0133] The second NN, referred to as PostDeepRx **1003a**, includes 2 convolutional layers and 1 ResNet in between. The kernel number of the input convolutional layer is 2 with input data dimension of $2 \times N_{\text{sub.f}} \times N_{\text{sub.t}}$. The kernel number of output convolutional layer depends on the modulation scheme.

[0134] Any other suitable NN structures may be used in place of the examples described with reference to the Figures.

[0135] The design of the output of DeepRx **1003b** and input of PostDeepRx **1003a** (of $2 \times N_{\text{sub.f}} \times N_{\text{sub.t}}$) may have two advantages.

[0136] One is to force the output of DeepRx **1003b** to accord with the iDFT deprecoding, whose output can be sequentially coupled to PostDeepRx **1003a**. DeepRx **1003b** thus opens up a 'window' for constellation surveillance at the output of iDFT deprecoding block **1002**. The intermediate constellation derived at the 2nd output branch may be perceived by human or machine type analysis for channel condition (e.g., nonlinearities, Dopplers) surveillance.

[0137] The other is to conduct PostDeepRx to learn a nonlinear demodulation detection, leaving DeepRx to serve as joint nonlinear channel estimator and equalizer. Thus, to some degree, it allows elaborate design of DeepRx and PostDeepRx according to the intermediate outcome of learned constellation patterns.

[0138] In both the first and second example embodiments as described above, the binary cross entropy may be used as a loss function. The formula is:

$$[00001] H = -\frac{1}{N} \sum_{i=1}^N y_i \log(P(y_i)) + (1 - y_i) \log(1 - P(y_i))$$

[0139] Where $y_{\text{sub.i}}$ represent binary bits 0/1 and $P(y_{\text{sub.i}})$ is the corresponding probability which is computed by feeding output LLRs to a sigmoid function. N is the total number of bits after channel encoding.

[0140] Non-Data RE positions are ignored for back propagation in training.

[0141] The deprecoding function block is fixed and not learned when training both ML models. The machine learning model may be trained either by Online Mode or Offline Mode. The offline training could be performed in other devices where model is not deployed.

[0142] The online training requires signaling and actions between both transmitter and receiver.

[0143] The devices for training the model may include functioning units in receivers (performing data set construction, data processing, model training, updating, deployment), transmitters

(preparing training data and send it over the air) and other platforms, which can perform all the related processes.

[0144] The method may comprise causing a trigger to be sent to an apparatus (e.g., a transmitter such as a user equipment) for training the machine learning mode (and, if present, the further machine learning mode) and receiving an acknowledgment from the apparatus in response to the request.

[0145] The method may comprise providing training configuration information (e.g., but not limited to, carrier frequency, number of subcarriers, MCS, rank, transform precoding enabling indication (DFT precoding), sequence random seed, and number of transmission time intervals (TTI)) to the apparatus, receiving training data from the apparatus in response to the configuration information and providing the training data to an entity for training the machine learning model (and, if present, the further machine learning model). The entity for training the machine learning model and further machine learning model may be located at a receiver, another base station such as a gNB or the cloud. The entity for training the machine learning model and the further machine learning model may be a Local Data Pool and Computing Unit (LDP&CU).

[0146] FIG. 12 shows an example signalling diagram for training the machine learning model in Online Mode.

[0147] In a first step **1201**, the receiver (e.g., BS for uplink transmission) triggers the online training or fine-tuning.

[0148] In a second step **1202**, the transmitter responds with acknowledges of training request.

[0149] In a third step **1203**, the receiver sends the training configurations, which may include carrier frequency, number of subcarriers, MCS, rank, transform precoding enabling indication (DFT precoding), sequence random seed, number of TTI required for training, etc.

[0150] In a fourth step **1204**, the transmitter sends the training sequence over the air. The training sequence should be known to receiver for computing loss.

[0151] In a fifth step **1205**, the receiver sends the data to a Local Data Pool and Computing Unit (LDP&CU).

[0152] In a sixth step **1206**, the model is trained in Computing Unit with training data in LDP.

[0153] In a seventh step **1207**, the CU sends the trained model to the Receiver user plane.

[0154] In an eighth step **1208**, the receiver deploys the model.

[0155] The model updating and finetuning may be viewed as part of online training process, which may be triggered periodically and non-periodically, by events. The steps for model updating and finetuning are as described above with respect to FIG. 12.

[0156] The receiver side may determine to deploy the machine learning model. For example, the method may comprise receiving deployment configuration information from a transmitter of the input signal and determining whether to deploy the machine learning model (and, if present, the further machine learning model) based on the deployment configuration information.

[0157] In an example embodiment, to apply the machine learning model for wireless transmission, a transmitter notifies the receiver with corresponding configurations. The receiver should determine to activate corresponding functioning blocks (such as deprecoding block) and select the corresponding neural network (NN) based on the configuration, before using DeepRx for signal processing.

[0158] The deployment configuration information may comprise at least one of an indication to perform the deprecoding on the frequency domain signal, subcarrier number information, modulation and coding scheme, rank and a fallback indicator.

[0159] FIG. 13 shows a signalling diagram for an example deployment of the DeepRx.

[0160] In step 1 **1301**, the transmitter sends configurations to the receiver, including transform-precoding enabling information, subcarrier number, rank, MCS, etc.

[0161] In step 2 **1302**, the receiver schedules if the DeepRx should be used. [0162] If not, fall back to conventional methods, [0163] If yes, go to Step 3

[0164] In step 3 **1303**, based on the configuration, the receiver determines to enable the deprecoding function block and selects the network for current rank, MCS, etc.

[0165] In step 4 **1304**, the transmitter sends user data to the receiver.

[0166] In step 5 **1305**, the receiver processes the data with DeepRx

[0167] To schedule the DeepRx, RRM scheduler may notify the user plane of the receiver with information for DeepRx including, DFT-precoding enabling information, PRB numbers, Rank number, MCS, Fallback indicator, etc.

[0168] The scheduling of DeepRx model for the first option and the second option is shown in FIGS. **14** and **15**, respectively. The scheduler **1401** notifies the deprecoding block **1402** in both proposed schemes. As shown in FIGS. **14** and **15**, the user plane signal processing blocks may be scheduled by RRM plane scheduler **1401** with information including at least one of transform-precoding (TP) enabling information, to activate the flexible deprecoding function block, subcarrier numbers or PRB numbers, for flexible deprecoding function (iDFT size), rank number (Currently only Rank 1 is supported for uplink DFTS-OFDM transmission in 3GPP), MCS, to determine the output kernel dimension of DeepRx and fallback indicator, to notify if the receiver should fall back to conventional methods or apply DeepRx.

[0169] In a first step, the RRM scheduler **1401** notifies DeepRx if DFT-precoding is enabled. In a second step, if DFT precoding is enabled, the deprecoding block **1402** for DeepRx is activated and if not the deprecoding function block **1402** is deactivated.

[0170] The scheduler may also schedule the Model Switch between OFDM and DFTS-OFDM, as well as Model Fallback to Conventional Receiver in corresponding scenarios. The method may comprise determining not to deploy the machine learning model (and, if present, the further machine learning model) based on the fallback indicator. For example, falling back to a conventional receiver may be triggered by the receiver side under conditions where the performance of DeepRx may deteriorate, e.g., continuous errors in transmission, etc.

[0171] The model falling back to conventional receiver may also trigger the Model Training (updating or finetuning as described above with reference to FIG. **12**).

[0172] The receiver determines whether to fall back to conventional methods.

[0173] If the receiver determines to fall back to conventional methods, the RRM plane scheduler notifies the User plane to fall back to conventional methods and the receiver applies conventional methods. If not, the RRM plane scheduler notifies the User plane to apply DeepRx and the receiver applies DeepRx (i.e. deploys the machine learning model).

[0174] Both of the proposed schemes have been tested with a real-life proof of concept, the results showing the benefits of invented receiver architecture under realistic circumstances. According to these proof-of-concept evaluations, the second option may enable a faster convergence in training.

[0175] The proposed DeepRx schemes were evaluated with data from a testbed for wireless transmission. The hardware nonlinearity exists and the DFT-precoding is enabled in data collection phase in order to lower the PAPR in transmission. The Tx signal propagated over the air and was captured by receiver at a distance of about 4 feet.

[0176] The Tx/Rx antenna numbers are both 1. 2 DMRS symbols are used to estimate the channel. The transmission modulation scheme is 64 QAM. Table 1 shows a list of Configuration in Evaluation.

TABLE-US-00001 TABLE 1 Parameters Configuration Tx/Rx 1/1 Modulation 64QAM Code Rate 873/1024 Subcarrier spacing ~30 MHz FFT size 512 Subcarrier number 300 (25RB) DMRS symbol 3, 12 DFT precoding Enabled

[0177] The proposed schemes were tested under the conditions with DFT-precoding enabled and compare them with conventional LMMSE receiver under configuration of 25 RB (300 subcarriers), code rate of 873/1024. There are 4000 subframes of data for training, and another 1000 subframes for inference.

[0178] FIGS. **16** to **18** present the verification results from testing data (to inter the performance on

data that was not pre-train). The uncoded and coded BER curves by evaluation are shown in FIG. **16** and FIG. **17**, respectively. The top curves represent the BER by using conventional LMMSE receiver. The next curves down represent the performance by using Pre-iDFT-Deprecoded DeepRx, and the bottom curves are obtained from the iDFT-Deprecoding Embedded hybrid DeepRx. [0179] The x axis is defined by $E_{\text{sub.RE}}/N$ where $E_{\text{sub.RE}}$ is the denoised signal power estimation and N is the noise estimation. In training phase, only the data at $E_{\text{sub.RE}}/N$ of 23.15 dB (last $E_{\text{sub.RE}}/N$ value in the figure) was employed, while in testing phase data from more $E_{\text{sub.RE}}/N$ were used for inference.

[0180] It is clearly observed that, under the 10% uncoded BER level, the first option DeepRx shows 0.6 dB gain over Practical LMMSE receiver, while the second option DeepRx outperforms the conventional LMMSE receiver by roughly 1.2 dB. The uncoded BER is decreased to 1/10 at training $E_{\text{sub.RE}}/N$. In Coded BER curves, the first option shows possible ~1 dB gain over LMMSE, while the second option DeepRx may achieve >2 dB gain under 100% coded BER level. The second option achieves the error-free performance at training $E_{\text{sub.RE}}/N$ while that from LMMSE stay at 1%~2% level.

[0181] There is also a faster convergence from the second option in the training process as shown by FIG. **18**. It can be seen that the second option is faster in convergence and it converges at lower loss/BER level than the first option, while by using previous DeepRx the NN is not trained up.

[0182] A constellation-like pattern **1900** as illustrated in FIG. **19** can be recorded by the 2nd output right after the embedded deprecoding layer from the iDFT-embedded hybrid DeepRx solution. It can be seen that the used the modulation scheme is 64QAM, albeit with some rotations. An inflation shape as marked by the black outline **1901** in FIG. **19** reflects the nonlinearity caused by power amplifier from the hardware of the testbed. Such a constellation-like pattern **1900** may reflect possible impairment in the transmission process. It may also help to understand the underlying mechanism of DeepRx.

[0183] Methods and apparatus as described with reference to FIGS. **7** to **15** augment DeepRx's compatibility with an DFTS-OFDM system. Much higher gain over a traditional LMMSE receiver for DFTS-OFDM maybe achieved, e.g, 1% BER using conventional LMMSE receiver can be reduced to error-free by proposed DeepRx approach.

[0184] The second example embodiment may provide a second constellation like output, which can unveil the nonlinearity in hardware etc, as well as make DeepRx more explainable.

[0185] An apparatus for a receiver may comprise means for receiving an input signal, based on a frequency domain signal, means for performing precoding on the received input signal and means for providing the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.

[0186] It should be understood that the apparatuses may comprise or be coupled to other units or modules etc., such as radio parts or radio heads, used in or for transmission and/or reception. Although the apparatuses have been described as one entity, different modules and memory may be implemented in one or more physical or logical entities.

[0187] It is noted that whilst some embodiments have been described in relation to 5G networks, similar principles can be applied in relation to other networks and communication systems. Therefore, although certain embodiments were described above by way of example with reference to certain example architectures for wireless networks, technologies and standards, embodiments may be applied to any other suitable forms of communication systems than those illustrated and described herein.

[0188] It is also noted herein that while the above describes example embodiments, there are several variations and modifications which may be made to the disclosed solution without departing from the scope of the present invention.

[0189] In general, the various embodiments may be implemented in hardware or special purpose circuitry, software, logic or any combination thereof. Some aspects of the disclosure may be

implemented in hardware, while other aspects may be implemented in firmware or software which may be executed by a controller, microprocessor or other computing device, although the disclosure is not limited thereto. While various aspects of the disclosure may be illustrated and described as block diagrams, flow charts, or using some other pictorial representation, it is well understood that these blocks, apparatus, systems, techniques or methods described herein may be implemented in, as non-limiting examples, hardware, software, firmware, special purpose circuits or logic, general purpose hardware or controller or other computing devices, or some combination thereof.

[0190] As used in this application, the term “circuitry” may refer to one or more or all of the following: [0191] (a) hardware-only circuit implementations (such as implementations in only analog and/or digital circuitry) and [0192] (b) combinations of hardware circuits and software, such as (as applicable): [0193] (i) a combination of analog and/or digital hardware circuit(s) with software/firmware and [0194] (ii) any portions of hardware processor(s) with software (including digital signal processor(s)), software, and memory(ies) that work together to cause an apparatus, such as a mobile phone or server, to perform various functions) and [0195] (c) hardware circuit(s) and or processor(s), such as a microprocessor(s) or a portion of a microprocessor(s), that requires software (e.g., firmware) for operation, but the software may not be present when it is not needed for operation.”

[0196] This definition of circuitry applies to all uses of this term in this application, including in any claims. As a further example, as used in this application, the term circuitry also covers an implementation of merely a hardware circuit or processor (or multiple processors) or portion of a hardware circuit or processor and its (or their) accompanying software and/or firmware. The term circuitry also covers, for example and if applicable to the particular claim element, a baseband integrated circuit or processor integrated circuit for a mobile device or a similar integrated circuit in server, a cellular network device, or other computing or network device.

[0197] The embodiments of this disclosure may be implemented by computer software executable by a data processor of the mobile device, such as in the processor entity, or by hardware, or by a combination of software and hardware. Computer software or program, also called program product, including software routines, applets and/or macros, may be stored in any apparatus-readable data storage medium and they comprise program instructions to perform particular tasks. A computer program product may comprise one or more computer-executable components which, when the program is run, are configured to carry out embodiments. The one or more computer-executable components may be at least one software code or portions of it.

[0198] Further in this regard it should be noted that any blocks of the logic flow as in the Figures may represent program steps, or interconnected logic circuits, blocks and functions, or a combination of program steps and logic circuits, blocks and functions. The software may be stored on such physical media as memory chips, or memory blocks implemented within the processor, magnetic media such as hard disk or floppy disks, and optical media such as for example DVD and the data variants thereof, CD. The physical media is a non-transitory media.

[0199] The memory may be of any type suitable to the local technical environment and may be implemented using any suitable data storage technology, such as semiconductor based memory devices, magnetic memory devices and systems, optical memory devices and systems, fixed memory and removable memory. The data processors may be of any type suitable to the local technical environment, and may comprise one or more of general purpose computers, special purpose computers, microprocessors, digital signal processors (DSPs), application specific integrated circuits (ASIC), FPGA, gate level circuits and processors based on multi core processor architecture, as non-limiting examples.

[0200] Embodiments of the disclosure may be practiced in various components such as integrated circuit modules. The design of integrated circuits is by and large a highly automated process. Complex and powerful software tools are available for converting a logic level design into a

semiconductor circuit design ready to be etched and formed on a semiconductor substrate.

[0201] The scope of protection sought for various embodiments of the disclosure is set out by the independent claims. The embodiments and features, if any, described in this specification that do not fall under the scope of the independent claims are to be interpreted as examples useful for understanding various embodiments of the disclosure.

[0202] The foregoing description has provided by way of non-limiting examples a full and informative description of the exemplary embodiment of this disclosure. However, various modifications and adaptations may become apparent to those skilled in the relevant arts in view of the foregoing description, when read in conjunction with the accompanying drawings and the appended claims. However, all such and similar modifications of the teachings of this disclosure will still fall within the scope of this invention as defined in the appended claims. Indeed, there is a further embodiment comprising a combination of one or more embodiments with any of the other embodiments previously discussed.

Claims

1. An apparatus for a receiver, the apparatus comprising: means for receiving an input signal, based on a frequency domain signal; means for performing deprecoding on the received input signal; and means for providing the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.
2. The apparatus according to claim 1, wherein the means for performing deprecoding comprise an inverse Discrete Fourier Transform, iDFT, deprecoding function.
3. The apparatus according to claim 1, comprising means for performing the deprecoding on a data branch of the input signal.
4. The apparatus according to claim 3, wherein the data branch comprises frequency-time grid symbols $N_f \times N_t$, where N_f comprises the number of subcarriers and N_t comprises number of orthogonal frequency-division multiplexing, OFDM, symbols.
5. The apparatus according to claim 3, comprising means for concatenating the deprecoded signal with a raw channel estimate branch of the frequency domain signal and providing the concatenated signal as the input for the machine learning model.
6. The apparatus according to claim 1, wherein the apparatus comprises means for providing the input signal, prior to deprecoding, to a further machine learning model for processing the input signal, and means for performing deprecoding on an output of the further machine learning model.
7. The apparatus according to claim 6, wherein the output of the further machine learning model is $2 \times N_f \times N_t$, where N_f comprises iDFT size and N_t comprises the number of orthogonal frequency-division multiplexing, OFDM, symbols.
8. The apparatus according to claim 7, wherein the output of the further machine learning model further comprises a constellation monitoring output.
9. The apparatus according to claim 1, comprising: means for causing a trigger to be sent to an apparatus for training the machine learning model and, if present, the further machine learning model; and means for receiving an acknowledgment from the apparatus in response to the request.
10. The apparatus according to claim 9, comprising means for providing training configuration information to the apparatus; means for receiving training data from the apparatus in response to the configuration information; and means for providing the training data to an entity for training the machine learning model and, if present, the further machine learning model.
11. The apparatus according to claim 1, comprising means for receiving deployment configuration information from a transmitter of the input signal; and means for determining whether to deploy the machine learning model and, if present, the further machine learning model based on the deployment configuration information.
12. The apparatus according to claim 11, wherein the deployment configuration information

comprises at least one of an indication to perform the deprecoding on the frequency domain signal, subcarrier number information, modulation and coding scheme, rank and a fallback indicator.

13. The apparatus according to claim 12, comprising means for determining not to deploy the machine learning model and, if present, the further machine learning model based on the fallback indicator.

14. A method comprising, at a receiver: receiving an input signal, based on a frequency domain signal; performing deprecoding on the received input signal; and providing the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.

15. An apparatus comprising: at least one processor and at least one memory including a computer program code, the at least one memory and computer program code configured to, with the at least one processor, cause the apparatus at least to, at a receiver: receive an input signal, based on a frequency domain signal; perform deprecoding on the received input signal; and provide the deprecoded signal as an input for a machine learning model, wherein the output of the machine learning model is a likelihood ratio.

16. (canceled)
