Systems, methods, and apparatuses for implementing self-supervised domain-adaptive pre-training via a transformer for use with medical image classification

Abstract

Described herein are systems, methods, and apparatuses for implementing self-supervised domain-adaptive pre-training via a transformer for use with medical image classification in the context of medical image analysis. An exemplary system includes means for receiving a first set of training data having non-medical photographic images; receiving a second set of training data with medical images; pre-training an AI model on the first set of training data with the non-medical photographic images; performing domain-adaptive pre-training of the AI model via self-supervised learning operations using the second set of training data having the medical images; generating a trained domain-adapted AI model by fine-tuning the AI model against the targeted medical diagnosis task using the second set of training data having the medical images; outputting the trained domain-adapted AI model; and executing the trained domain-adapted AI model to generate a predicted medical diagnosis from an input image not present within the training data.

Background/Summary

CLAIM OF PRIORITY (1) This non-provisional U.S. Utility Patent Application is related to, and claims priority to the U.S. Provisional Patent Application No. 63/323,988, entitled “SYSTEMS, METHODS, AND APPARATUSES FOR IMPLEMENTING BENCHMARKING VISION TRANSFORMERS FOR USE WITH CHEST X-RAYS CLASSIFICATION,” filed Mar. 25, 2022, and is further related to, and claims priority to, the U.S. Provisional Patent Application No. 63/405,262, entitled “SYSTEMS, METHODS, AND APPARATUSES FOR IMPLEMENTING SELF-SUPERVISED DOMAIN-ADAPTIVE PRE-TRAINING WITH A TRANSFORMER FOR USE WITH MEDICAL IMAGE CLASSIFICATION,” filed Sep. 9, 2022, the entire contents of each being incorporated herein by reference as though set forth in full.

COPYRIGHT NOTICE

(1) A portion of the disclosure of this patent document contains material which is subject to copyright protection. The copyright owner has no objection to the facsimile reproduction by anyone of the patent document or the patent disclosure, as it appears in the Patent and Trademark Office patent file or records, but otherwise reserves all copyright rights whatsoever.

TECHNICAL FIELD

(2) Embodiments of the invention relate generally to the field of medical imaging and analysis using convolutional neural networks and transformers for the classification and annotation of medical images, and more particularly, to systems, methods, and apparatuses for implementing self-supervised domain-adaptive pre-training via a transformer for use with medical image classification in the context of medical image analysis and additionally relate to the systems, methods, and apparatuses for systematically benchmarking vision transformers for use with chest x-ray classification, specifically in which trained models are utilized for processing medical images.

BACKGROUND

(3) The subject matter discussed in the background section should not be assumed to be prior art merely as a result of its mention in the background section. Similarly, a problem mentioned in the background section or associated with the subject matter of the background section should not be assumed to have been previously recognized in the prior art. The subject matter in the background section merely represents different approaches, which in and of themselves may also correspond to embodiments of the claimed inventions.

(4) Machine learning models have various applications to automatically process inputs and produce outputs considering situational factors and learned information to improve output quality. One area where machine learning models, and neural networks in particular, provide high utility is in the field of processing medical images.

(5) Within the context of machine learning and with regard to deep learning specifically, a Convolutional Neural Network (CNN, or ConvNet) is a class of deep neural networks, very often applied to analyzing visual imagery. Convolutional Neural Networks are regularized versions of multilayer perceptrons. Multilayer perceptrons are fully connected networks, such that each neuron in one layer is connected to all neurons in the next layer, a characteristic which often leads to a problem of overfitting of the data and the need for model regularization. Convolutional Neural Networks also seek to apply model regularization, but with a distinct approach. Specifically, CNNs take advantage of the hierarchical pattern in data and assemble more complex patterns using

smaller and simpler patterns. Consequently, on the scale of connectedness and complexity, CNNs are on the lower extreme.

(6) Also used within the context of machine learning are Vision Transformers (ViTs). A Vision Transformer is a transformer that is targeted at vision processing tasks such as image recognition. Transformers found their initial applications in natural language processing (NLP) tasks, as demonstrated by language models such as BERT and GPT-3. By contrast, the typical image processing system uses a convolutional neural network (CNN). Well-known projects include Xception, ResNet, EfficientNet, DenseNet, and Inception.

(7) Image transformers operate by dividing an image into fixed-size patches, correctly embedding each of the patches, and concatenating positional embedding as an input to a transformer encoder. While the transformer architecture has become the de-facto standard for natural language processing tasks, its applications to computer vision are only now being realized. For instance, the Vision Transformer (ViT) type image transformer attains excellent results compared to state-of-the-art convolutional networks while requiring substantially fewer computational resources to train, while a Swin transformer can serve as a general-purpose backbone for computer vision. Challenges remain, however, in adapting transformers from language to vision due to differences between the two domains, such as large variations in the scale of visual entities and the high resolution of pixels in images compared to words in text.

(8) Unlike CNNs, Transformers measure the relationships between pairs of input tokens (words in the case of text strings), termed attention. The cost is exponential with the number of tokens. For images, the basic unit of analysis is the pixel. However, computing relationships for every pixel pair in a typical image is prohibitive in terms of memory and computation. Instead, ViT computes relationships among pixels in various small sections of the image (e.g., 16×16 pixels), at a drastically reduced cost. The sections (with positional embeddings) are placed in a sequence. The embeddings are learnable vectors. Each section is arranged into a linear sequence and multiplied by the embedding matrix. The result, with the position embedding is fed to the transformer. The architecture for image classification is the most common and uses only the Transformer Encoder in order to transform the various input tokens. However, there are also other applications in which the decoder part of the traditional Transformer Architecture is also used.

(9) Heretofore, self-supervised learning has been sparsely applied in the field of medical imaging. Nevertheless, there is a massive need to provide automated analysis to medical imaging with a high degree of accuracy so as to improve diagnosis capabilities, control medical costs, and to reduce workload burdens placed upon medical professionals.

(10) Not only is annotating medical images tedious and time-consuming, but it also demands costly, specialty-oriented expertise, which is not easily accessible.

(11) What is needed is an improved technique for leveraging the capabilities of vision transformer methodologies.

(12) The present state of the art may therefore benefit from the systems, methods, and apparatuses for systematically benchmarking vision transformers for use with chest x-ray classification, and may further benefit from the systems, methods, and apparatuses for implementing self-supervised domain-adaptive pre-training via a transformer for use with medical image classification, each being described herein.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

(1) Embodiments are illustrated by way of example, and not by way of limitation, and can be more fully understood with reference to the following detailed description when considered in connection with the figures in which:

- (2) FIGS. 1A, 1B, and 1C depict that within the context of medical imaging, good initialization is more vital for transformer-based models than for CNNs, in accordance with described embodiments;
- (3) FIG. 2 depicts Table 1 which shows that a self-supervised SimMIM model with the Swin-B backbone outperforms fully-supervised baselines, in accordance with described embodiments;
- (4) FIG. 3 depicts Table 2 which shows that domain-adapted pre-trained model which utilized a large number of in-domain data (e.g., X-rays(926K)) in an SSL manner achieves the best performance across all five target tasks, in accordance with described embodiments;
- (5) FIG. 4 depicts Table 3 which shows benchmarking transfer learning with transformers (e.g., using ViT-B and Swin-B transformers) ImageNet pre-trained models on six medical image classification tasks, in accordance with described embodiments;
- (6) FIG. 5 depicts Table 4 which shows the creation of a large-scale dataset, namely X-ray(926K), by collecting 926,028 images from 13 different chest X-ray datasets, in accordance with described embodiments;
- (7) FIG. 6 depicts Table 5 shows that continual pre-training on a large-scale domain-specific dataset (ImageNet.fwdarw.X-ray(926K)) via self-supervised SimMIM method achieves state-of-the-art performance on the NIH ChestX-ray14 target task, in accordance with described embodiments;
- (8) FIGS. 7A and 7B depict a flow diagram illustrating a method for systematically implementing self-supervised domain-adaptive pre-training via a transformer for use with medical image classification, in accordance with disclosed embodiments;
- (9) FIG. 8 depicts Table 6 illustrating performance of the disclosed methodology when compared with prior known techniques;
- (10) FIG. 9 depicts a chart showing a comparison of classification results on the NIH ChestX-ray14 dataset;
- (11) FIG. 10A depicts Table 7 at element showing the performance of the disclosed methodology for different pre-training data sets;
- (12) FIG. 10B depicts a chart showing the results of pre-training on out-domain and in-domain data;
- (13) FIG. 11 shows a diagrammatic representation of a system within which embodiments may operate, be installed, integrated, or configured;
- (14) FIGS. 12A and 12B depict a flow diagram illustrating a method for systematically benchmarking vision transformers for use with chest x-ray classification, in accordance with disclosed embodiments; and
- (15) FIG. 13 illustrates a diagrammatic representation of a machine in the exemplary form of a computer system, in accordance with one embodiment.

DETAILED DESCRIPTION

- (16) Described herein are systems, methods, and apparatuses for implementing self-supervised domain-adaptive pre-training via a transformer for use with medical image classification in the context of medical image analysis. Further described are systems, methods, and apparatuses for systematically benchmarking vision transformers for use with chest x-ray classification.
- (17) In the field of medical image analysis, vision transformer-based self-supervised learning (SSL) approaches have recently shown substantial success in the computer vision technical arts as such approaches outrank convolutional neural networks (CNNs) in one representative visual benchmark after another. However, the competition between visual transformers and CNNs in medical imaging is rarely studied, leaving many important questions unanswered.
- (18) Set forth herein are benchmarks demonstrating how well existing transformer variants that use various (supervised and self-supervised) pre-training techniques perform against CNNs on a variety of medical classification tasks. Given the data-hungry nature of transformers and the annotation-deficiency challenge of medical imaging, a practical approach is described herein for bridging the

domain gap between photographic and medical images by utilizing unlabeled large-scale in-domain data.

(19) Through extensive empirical evaluations, the following insights in medical imaging are revealed: First, good initialization is more crucial for transformer-based models than for CNNs. Secondly, self-supervised learning based on masked image modeling captures more generalizable representations than supervised models. Third, assembling a larger-scale domain-specific dataset can better bridge the domain gap between photographic and medical images via self-supervised continuous pre-training.

(20) Through the benchmark study set forth below and the novel methodologies for bridging the domain gap between photographic and medical images through the use of unlabeled large-scale in-domain data, future research may thus build upon the inventive concepts set forth herein and thus extend the capability of applying transformers to medical imaging analysis.

Introduction

(21) Visual transformers have recently demonstrated the potential to be considered a viable alternative to CNNs in visual recognition. Though visual transformers have attained state-of-the-art (SOTA) performance across a variety of computer vision tasks, their architectures lack convolutional inductive bias, making them more data-hungry than prior known CNN architectures and techniques.

(22) Given the data-hungry nature of transformers and the challenge of annotation scarcity in medical imaging, the efficacy of existing visual transformers in medical imaging is unknown. The analysis set forth herein reveals that on medical target tasks with limited annotated data, transformers lag behind CNNs in random initialization (scratch) settings. To overcome the challenge of annotation dearth in medical imaging, transfer learning from ImageNet pre-trained models has become a common practice.

(23) As such, the inventors sought out to answer the following question: “To what extent can ImageNet pre-training elevate transformers' performance to rival CNNs in medical imaging?”

(24) Meanwhile, self-supervised learning (SSL) has drawn great attention in medical imaging due to its remarkable success in overcoming the challenge of annotation dearth in medical imaging. The goal of the SSL paradigm is to learn general-purpose representations without using human-annotated labels. Masked image modeling (MIM) methods, in addition to supervised pre-training, have recently emerged as promising SSL techniques for transformer models. The basic idea behind MIM-based methods is to learn representations by (randomly) masking portions of the input image and then recovering the input image at the masked areas. Recent advancements in MIM-based techniques have resulted in SSL techniques that outperform supervised pre-trained models in a variety of computer vision tasks. As a result, the inventors further sought to answer the additional question: “How generalizable are MIM-based self-supervised methods to medical imaging in comparison to supervised ImageNet pre-trained models?”

(25) Further still, the marked differences between photographic and medical images may result in a mismatch in learned features between the two domains, which is referred to as a “domain gap.” Recent advancements demonstrate that using a CNN as the backbone, a moderately-sized medical image dataset is sufficient to bridge the domain gap between photographic and medical images via supervised continual pre-training. Again, owing to the data-hungry nature of transformers, the inventors investigated domain-adaptive pre-training in an SSL setting, thus arriving upon a third question to be answered, as follows: “How to scale up a domain-specific dataset for a transformer architecture to bridge the domain gap between photographic and medical images?”

(26) In the context of addressing the three questions above, a benchmarking study was conducted to assess the efficacy of transformer-based models on numerous medical classification tasks involving different diseases (thorax diseases, lung pulmonary embolism, and tuberculosis) and modalities (X-ray and CT) and to develop the new innovative methodologies which are described in greater detail below.

(27) Very specifically, the benchmarking study (1) investigated the importance of pre-training for transformers versus CNNs in medical imaging; (2) assessed the transferability of state-of-the-art MIM-based self-supervised method to a diverse set of medical image classification tasks; and (3) investigated domain-adaptive pre-training on large-scale photographic and medical images to tailor self-supervised ImageNet models for target tasks on chest X-rays.

(28) An extensive empirical study yielded the following findings: Firstly, (1) In medical imaging, good initialization is more vital for transformer-based models than for CNNs (see FIGS. 1A, 1B, and 1C); secondly, (2) MIM-based self-supervised methods capture finer-grained representations that can be useful for medical tasks better than supervised pre-trained models (see Table 1 as set forth at FIG. 2); and thirdly, (3) Continuous self-supervised pre-training of the self-supervised ImageNet model on large-scale medical images bridges the domain gap between photographic and medical images, providing more generalizable pre-trained models for medical image classification tasks (see Table 2 as set forth at FIG. 3). The benchmarking study is additionally contrasted with related works in the remarks that follow to help further emphasize the novel techniques which are presented herein.

(29) Benchmarking Setup:

(30) Transformer Backbones—In the target tasks in all experiments, two representative recent state-of-the-art transformer backbones were taken, including Vision Transformer (ViT) and Swin Transformer (Swin). Visual transformer models, which have recently emerged as alternatives to convolutional neural networks (CNNs), have revolutionized computer vision fields. The groundbreaking work of ViT showcases how transformers can completely replace the CNNs backbone with a convolution-free model. Although ViT attains state-of-the-art image classification performance, the ViT transformer architecture may not be suitable for use on dense vision tasks, such as object detection, segmentation, etc. Conversely, the Swin transformer architecture utilizes a general-purpose transformer backbone to address this problem by building hierarchical feature maps, resulting in state-of-the-art accuracy on object detection segmentation tasks.

(31) For transfer learning to the classification target tasks, the transformer is taken as a pre-trained model and a task-specific classification head is then added. The transfer learning performance of all pre-trained models are further assessed by fine-tuning all layers in the downstream networks.

(32) Target Tasks and Datasets—Further considered are a diverse suite of six common but challenging medical classification tasks including NIH ChestX-ray14, CheXpert, VinDr-CXR, NIH Shenzhen CXR, RSNA PE Detection, and RSNA Pneumonia. These tasks encompass various diseases (thorax diseases, lung pulmonary embolism, and tuberculosis) and modalities (X-ray and CT). The evaluations conducted adopted the official split of these datasets, when available. Otherwise, the data was randomly divided into 80% and 20% subsets for training and testing, respectively.

(33) AUC (area under the ROC curve) was used to measure the performance of multi-label classification target tasks (e.g., NIH ChestXray14, CheXpert, and VinDr-CXR) and binary classification target tasks (e.g., NIH Shenzhen CXR and RSNA PE). Accuracy was used to evaluate multi-class classification target task (RSNA Pneumonia) performance. The mean and standard deviation of performance metrics over ten runs were reported for all experiments, and statistical analyses based on an independent two sample t-test are presented below.

(34) FIGS. 1A, 1B, and 1C depict that within the context of medical imaging, good initialization is more vital for transformer-based models than for CNNs.

(35) Specifically shown at FIG. 1A are results for the NIH ChestX-ray14 (element 171) and CheXpert at element 172. FIG. 1B provides results for NIH Shenzhen CXR at element 173 and VinDr-CXR at element 174. FIG. 1C provides results for RSNA Pneumonia at element 175 and RSNA PE at element 176. All are provided with AUC % results across ViT-B (element 177), Swin-B (element 178), and R-50 (element 179) according to the training methods set forth by the key at element 180.

(36) For instance, when training from scratch, transformers performed significantly worse than CNNs on all target tasks. However, with supervised or self-supervised pre-training on ImageNet, transformers were demonstrated to offer the same results as CNNs, highlighting the importance of pre-training when using transformers for medical imaging tasks. Statistical analysis was further conducted between the best of six pre-trained transformer models and the best of three pre-trained CNN models.

(37) Benchmarking Transformers

(38) Pre-training is more vital for transformer-based models than for CNNs in medical imaging: Transformers have recently attained state-of-the-art results and surpassed CNNs in a variety of computer vision tasks. However, the lack of convolutional inductive bias in transformer architectures makes them more data-hungry than CNNs. Therefore, to rival CNNs in vision tasks, transformers require millions and even sometimes, billions of labeled data. Given the data-hungry nature of transformers and the challenge of annotation scarcity in medical imaging, it is natural to question whether transformers can compete with CNNs when used directly on medical imaging applications.

(39) Preliminary analysis shows that in random initialization settings (e.g., initializing from scratch), transformers lag behind CNNs on medical target tasks with limited annotated data. Taken together, it was therefore hypothesized that in medical imaging, transformers require pre-trained models to rival with CNNs. To put this hypothesis to the test, experiments were conducted to empirically validate how well the transformer variants (ViT-B and Swin-B) that use various (supervised and self-supervised) pre-training methods compete with CNNs on a range of medical classification tasks. Specifically, six newly-developed transformer models and three CNN models were benchmarked.

(40) Experimental Setup: The transferability of various popular transformer methods were evaluated with officially released models on six diverse medical classification tasks. The goal was to investigate the importance of pre-training for transformers versus CNNs in medical imaging. In view of this goal, six popular transformer pre-trained models with ViT-B and Swin-B backbones were used as well as three standard CNNs pre-trained models with ResNet-50 backbones that are already official and ready to use. Specifically, for supervised pre-training, the official pre-trained ViT-B, Swin-B, and ResNet-50 on ImageNet-21K and pre-trained Swin-B and ResNet-50 on ImageNet-1K pre-trained models were utilized. For self-supervised pre-training, the pre-trained ViT-B and Swin-B models were utilized with simMIM on ImageNet1K, as well as pre-trained ViT-B and ResNet-50 models with MoCo v3 on ImageNet-1K. The differences in pre-training data (ImageNet-1K or ImageNet-21K) are due to the availability of official pre-trained models.

(41) Results and Analysis: The results of the evaluations as set forth at FIGS. 1A, 1B, and 1C, suggest three major findings. Firstly, in random initialization (scratch) settings (horizontal lines), transformers (e.g., ViT-B and/or Swin-B) cannot compete with CNNs (e.g., such as ResNet-50) in medical applications, as they offer performance equal to or even worse than CNNs. This inferior performance is attributable to the respective transformer's lack of desirable inductive bias in comparison to CNNs, which has a negative impact on transformer performance on medical target tasks with limited annotated data. Secondly, Swin-B backbone consistently outperforms ViT-B across all target tasks. This reveals the importance of hierarchical inductive bias, embedded in the Swin-B backbone, in elevating the performance of transformer-based models in medical image analysis. Thirdly, with supervised or self-supervised pre-training on ImageNet, transformers can offer competitive performance in comparison to CNNs, emphasizing the importance of pre-training when using transformers for medical imaging tasks. In particular, the best of six pre-trained transformer models outperform the best of three pre-trained CNN models in all target tasks, with the exception of NIH Shenzhen CXR, which can be attributed to a lack of sufficient training data (only 463 samples).

(42) Self-supervised learning based on masked image modeling is a preferable option to supervised

baselines for medical imaging: Visual transformer models, while powerful, are nevertheless prone to over-fitting and rely heavily on supervised pre-training on large-scale image datasets, such as JFT-300M and ImageNet-21K. In addition to supervised pre-training, self-supervised learning (SSL) techniques account for a substantial part of pre-trained transformer models.

(43) Masked Image Modeling (MIM) is an approach in which portions of the input image signals are randomly masked and then the original input signals are subsequently recovered at the masked area. Such a technique has recently received great attention in computer vision for pre-training transformers in a self-supervised manner. The MIM-based self-supervised methods are widely accepted to capture more task-agnostic features than supervised pre-trained models, making them better suited for fine-tuning on various vision tasks.

(44) It was therefore hypothesized that existing self-supervised transformer models pre-trained on photographic images would outperform supervised transformer models in the medical image domain, where there is a significant domain shift between medical and photographic images. To test this hypothesis, two recent state-of-the-art transformer backbones were considered, namely ViT-B and Swin-B, and experiments then compared their supervised and self-supervised pre-trained models for various medical image classification tasks.

(45) Experimental Setup: To investigate the efficacy of self-supervised and supervised pre-trained transformer models in medical imaging, the experiments utilized existing supervised and state-of-the-art self-supervised (e.g., SimMIM) pre-trained models with two representative transformer backbones, ViT-B and Swin-B; all pre-trained models are fine-tuned on six different medical classification tasks.

(46) To provide a comprehensive evaluation, results are also included for the training of these two architectures from scratch. SimMIM was utilized instead of the concurrent MAE as the representative MIM-based method because SimMIM has demonstrated superior performance to MAE in medical image analysis.

(47) FIG. 2 depicts Table 1 (element **201**) which shows that a self-supervised SimMIM model with the Swin-B backbone outperforms fully-supervised baselines, in accordance with described embodiments. The best methods are bolded while the second best are underlined. For every target task, statistical analysis was conducted between the best (bolded) vs. others. The shaded/highlighted boxes indicate no statistically significant difference at the $p=0.05$ level.

(48) Results and Analysis: As shown in Table 1, the self-supervised SimMIM model with the Swin-B backbone performs significantly better or on-par compared with both supervised baselines with either ViT-B or Swin-B backbones across all target tasks. The same observation of MIM-based models outperforming their supervised counterparts also exists in the finer-grained visual tasks, e.g., object detection and medical image segmentation.

(49) Rather than the finer-grained visual tasks, the evaluation results of Table 1 focused on coarse-grained classification tasks. Furthermore, it was observed that the SimMIM model with the Swin-B backbone consistently outperforms its counterpart with the ViT-B backbone in all cases, implying that the Swin-B backbone may be a superior option for medical imaging tasks to ViT-B. These findings suggest that the self-supervised SimMIM model with the Swin-B backbone could be a viable option for pre-training deep models in medical imaging applications.

(50) Self-supervised domain-adaptive pre-training on a larger-scale domain-specific dataset better bridges the domain gap between photographic and medical imaging: Domain adaptation seeks to improve target model performance by reducing domain disparities between source and target domains. It has been demonstrated that domain-adaptive pre-training can bridge the domain gap between natural and medical images. Particularly, by first pre-training a CNN model (e.g., ResNet-50) on ImageNet and then training on domain-specific datasets (e.g., NIH ChestX-ray14 or CheXpert), it has been shown that domain-adaptive pre-training can tailor the ImageNet models to medical applications.

(51) Therefore, domain-adaptive pre-training was investigated in the context of visual transformer

architectures. Given the data-hungry nature of transformers and the annotation-dearth challenge of medical imaging, the SSL pre-training approach was used to bridge the domain gap between photographic and medical images. Since no expert annotation is required in SSL pre-training, it was possible to assemble multiple domain-specific datasets into a large-scale dataset, overcoming the limitations of prior known techniques which have been limited to using only a single dataset.

(52) **Experimental Setup:** The transferability of five different self-supervised SimMIM models were evaluated with the Swin-B backbone by utilizing three different pre-training datasets, including ImageNet, ChestX-ray14, and X-rays(926K), which is a large-scale dataset that was created by collecting 926,028 images from 13 different chest X-ray datasets. To do so, the evaluation utilized the SimMIM released ImageNet model as well as two models pre-trained on ChestX-ray14 and X-rays(926K) using SimMIM. Still further, two new models were created that were initialized through the self-supervised ImageNet pre-trained model followed by self-supervised pre-training on ChestX-ray14 (ImageNet.fwdarw.ChestX-ray14) and X-rays(926K) (ImageNet.fwdarw.X-rays(926K)). Every pre-training experiment was trained for 100 epochs using the default SimMIM settings.

(53) **FIG. 3** depicts Table 2 (element **301**) which shows that domain-adapted pre-trained model which utilized a large number of in-domain data (e.g., X-rays(926K)) in an SSL manner achieves the best performance across all five target tasks, in accordance with described embodiments. The best methods are bolded while the second best are underlined. For each target task, the independent two sample t-test was conducted between the best (bolded) vs. the others. The absence of a statistically significant difference at the $p=0.05$ level is indicated by shaded/highlighted boxes.

(54) **Results and Analysis:** The following observations may be drawn from the results as set forth by Table 2. Firstly, (1) the X-rays(926K) model consistently outperforms the ChestX-ray14 model in all cases. This observation suggests that scaling the pre-training data can significantly improve the self-supervised transformer models. Secondly, (2) while the X-rays(926K) model uses fewer images in the pre-training dataset than the ImageNet model, it shows superior or comparable performance over the ImageNet model across all target tasks. This implies that, whenever possible, in-domain medical transfer learning should be preferred over ImageNet transfer learning. Thirdly, (3) the overall trend highlights the benefit of domain-adaptive pre-training, which leverages the ImageNet model's learning experience and further refines it with domain-relevant data.

(55) Specifically, fine-tuning both domain-adapted models (ImageNet.fwdarw.ChestX-ray14 and ImageNet.fwdarw.X-rays(926K)) outperforms ImageNet and corresponding in-domain models in all target tasks, with one exception. As shown by the results of Table 2, for CheXpert, the ImageNet.fwdarw.ChestX-ray14 model performs worse in CheXpert than the corresponding ImageNet model. This exception suggests that the in-domain pre-training dataset should be larger than the target dataset. It is noteworthy that this gap was filled later by ImageNet.fwdarw.X-rays(926K) model, which utilized more in-domain data. This highlights the significance of larger-scale medical data in improving the transformers' ability to learn more discriminative representations.

(56) **FIG. 4** depicts Table 3 (element **401**) which shows benchmarking transfer learning with transformers (e.g., using ViT-B and Swin-B transformers) ImageNet pre-trained models on six medical image classification tasks, in accordance with described embodiments. The best methods are bolded while the second best are underlined. For each target task, the independent two sample t-test was conducted between the best (bolded) vs. the others. The absence of a statistically significant difference at the $p=0.05$ level is indicated by shaded/highlighted boxes. For comparison with CNNs, four pre-trained models were evaluated with ResNet-50 backbones. To provide a comprehensive evaluation, results for the training of these three architectures from scratch is also provided.

(57) **FIG. 5** depicts Table 4 (element **501**) which shows the creation of a large-scale dataset, namely X-ray(926K), by collecting 926,028 images from 13 different chest X-ray datasets, in accordance

with described embodiments. For the datasets that have an official training and testing data split, only the training set portion was utilized.

(58) The Large-Scale Domain-Specific Dataset

(59) Given the data-hungry nature of transformers and the annotation-deficiency challenge of medical imaging, a practical approach for bridging the domain gap between photographic and medical images is provided through the utilization of unlabeled large-scale in-domain data. Specifically, 926,028 images were assembled from 13 chest X-ray datasets into a single aggregated large-scale dataset. Each of the datasets used are listed at Table 4 as set forth by FIG. 5, discussed above.

(60) FIG. 6 depicts Table 5 (element 601) shows that continual pre-training on a large-scale domain-specific dataset (ImageNet.fwdarw.X-ray(926K)) via self-supervised SimMIM method achieves state-of-the-art performance on the NIH ChestX-ray14 target task, in accordance with described embodiments.

(61) State-of-the-Art Performance

(62) The domain-adapted model pre-trained using the large-scale domain-specific dataset that was assembled, (e.g., the X-ray(926K)), achieves state-of-the-art performance when transferred to the NIH ChestX-ray14 dataset. The result of the best model evaluated is presented by Table 5, with the results of other state-of-the-art methods.

(63) Improvements Over all Prior Known Methodologies

(64) The described methodologies and techniques as set forth herein go far beyond the mere benchmarking of existing transformer models for medical imaging. Importantly, a domain-adaptive continual pre-training strategy has been disclosed which critically operates in a purely self-supervised manner using a large-scale domain-specific dataset. Such a technique has never been successfully demonstrated before, much less in the context of medical imaging.

(65) Unlike prior known techniques which apply transformers to medical imaging, the novel methodologies as set forth herein not only are used to demonstrate a successful evaluation of the capabilities, especially with respect to transferabilities of various transformer models on medical tasks, but also shows how to improve their performance for specific medical tasks.

(66) For instance, according to an exemplary embodiment, the transformer's performance is strengthened by gradually scaling up the pre-training data to 926,028 images from 13 different sources (refer again to the results discussed above with reference to Table 2 as set forth at FIG. 3).

(67) Unfortunately, datasets created at different sites tend to be annotated differently, resulting in a historical lack of compatibility between them. For example, ChestX-ray14, CheXpert, MIMIC-CXR, and VinDr-CXR are all datasets for chest X-rays, but VinDr-CXR is associated with global (image-level) and local (boxed-lesions) labels. Similarly, the MIMIC-CXR dataset has no expert annotations whatsoever, and yet is provided with associated radiological reports. Each of ChestX-ray14 and CheXpert cover 14 conditions at the image level, and their 14 conditions have overlaps, and yet, are not exactly the same.

(68) As described herein, through the utilization of datasets from different sources (sites, hospitals, medical centers, etc.), it is possible and preferable to increase data diversity which thus in turn, boosts the potential performance and robustness of the trained models. And yet, supervised learning techniques simply cannot handle this annotation disparity between available datasets.

(69) Thus, the ability to overcome and bridge the gap between the divergent domains results in improvements to, and a significant contribution to the field of medical image analysis and classification through the use of the self-supervised domain-adaptive strategy set forth herein which specifically operates to scale up data utilization for pre-training (refer again to the discussion above entitled "Self-supervised domain-adaptive pre-training on a larger-scale domain-specific dataset better bridges the domain gap between photographic and medical imaging.").

(70) Consequently, the evaluation results provided at Table 2 as set forth at FIG. 3 show that the novel self-supervised domain-adaptive strategy, when used in conjunction with scaling up the pre-

training data from multiple sources (e.g., such as disparate sites, hospitals, medical centers, etc.) significantly improves the performance of transformer models on medical tasks.

(71) For instance, by training a domain-adapted model (ImageNet.fwdarw.X-rays(926K)), which leverages the learning experience with photographic images and further refines via self-supervision with large-scale domain-relevant data, the best performance across all target tasks was demonstrably achieved. Through the use and practice of the novel techniques presented herein, contributions to the advancement of the field of medical imaging analysis includes at least the following important contributions: (1) First, a systematic benchmarking analysis of the performance of existing transformer variants against CNNs that use various (supervised and self-supervised) pre-training methods on a variety of medical classification tasks. (2) Second, a successfully validated technique for bridging the domain gap between photographic and medical images by utilizing a largescale in-domain dataset from multiple sources via self-supervision. (3) Third, a collection of domain-specific models that offer state-of-the-art performance by pre-training first with photographic images (e.g., with the photographic images being from a first domain type) and then adapting via self-supervision with large-scale medical images (e.g., with the medical images being from second domain type). (4) Fourth, a set of answers to three critical questions about transformers used in medical imaging, revealing the following insights: (i) firstly, that good initialization is more crucial for transformer-based models than for CNNs, (ii) self-supervised learning may capture more generalizable representations than supervised learning, and (iii) using a larger-scale domain-specific dataset can bridge the domain gap between photographic and medical images via self-supervised continuous pre-training.

(72) Benefits of the Disclosed Methodologies

(73) The described embodiments therefore manifest an up-to-date benchmark study which sheds light on the efficacy and limitations of existing visual transformer models in medical image classification when compared to CNN counterparts. The extensive experiments yield important findings: Firstly, (1) a good pre-train model can allow visual transformers to compete with CNNs on medical target tasks with limited annotated data; secondly, (2) MIM-based self-supervised methods, such as SimMIM, play an important role in pre-training visual transformer models, preventing them from over-fitting in medical target tasks; and thirdly, (3) assembling multiple domain-specific datasets into a single aggregated larger-scale dataset can better bridge the domain gap between photographic domain images and medical domain imaging via continual SSL pre-training.

(74) Although many transformer-based U-Net architectures have been developed for 3D medical image segmentation, it is nevertheless helpful to perform the comprehensive benchmarking study of transformers for medical image analysis. Thus, through the utilization of the novel methodologies set forth herein, further evaluation of additional modalities and medical image segmentation tasks may prove beneficial to the state of the art.

(75) FIGS. 7A and 7B depict a flow diagram illustrating a method **701-702** for systematically implementing self-supervised domain-adaptive pre-training via a transformer for use with medical image classification, in accordance with disclosed embodiments. Method **701-702** may be performed by processing logic that may include hardware (e.g., circuitry, dedicated logic, programmable logic, microcode, etc.), software (e.g., instructions run on a processing device) to perform various operations such as designing, defining, retrieving, parsing, persisting, exposing, loading, executing, operating, receiving, generating, storing, maintaining, creating, returning, presenting, interfacing, communicating, transmitting, querying, processing, providing, determining, triggering, displaying, updating, sending, etc., in pursuance of the systems and methods as described herein. For example, the system **1101** (see FIG. 11) and the machine **1301** (see FIG. 13) and the other supporting systems and components as described herein may implement the described methodologies. Some of the blocks and/or operations listed below are optional in accordance with certain embodiments. The numbering of the blocks presented is for the sake of clarity and is not

intended to prescribe an order of operations in which the various blocks must occur.

(76) With reference to the method **701-702** depicted at FIGS. 7A and 7B, starting at block **705**, there is a method performed by executing instructions via the processor of a specially configured system for systematically implementing self-supervised domain-adaptive pre-training via a transformer for use with medical image classification. Such a system may be configured with at least a processor and a memory to execute specialized instructions which cause the system to perform the following operations:

(77) At block **710**, processing logic receives a first set of training data which includes photographic images unrelated to a targeted medical diagnosis task.

(78) At block **715**, processing logic receives a second set of training data which includes a plurality of medical images derived from multiple distinct sources, in which the plurality of medical images are configured with multiple inconsistent annotation and classification data.

(79) At block **720**, processing logic Pre-training an AI model on the first set of training data which includes the photographic images by learning image classification from the photographic images within the first set of training data.

(80) Transitioning from FIG. 7A to the processing which continues at FIG. 7B, the processing of method **701-702** resumes at block **730**.

(81) At block **730**, processing logic executes instructions via the processor of the system for performing domain-adaptive pre-training of the AI model via self-supervised learning operations, in which the AI model previously trained on the first set of training data applies domain-adaptive learning to scale up data utilization of the second set of training data within the AI model's learned image classifications.

(82) At block **735**, processing logic generates a trained domain-adapted AI model by fine-tuning the AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images.

(83) At block **740**, processing logic outputs the trained domain-adapted AI model.

(84) At block **745**, processing logic executes the trained domain-adapted AI model to generate a predicted medical diagnosis from an input image which forms no part of the first or second sets of training data.

(85) According to another embodiment of method **701-702**, pre-training the AI model on the first set of training data generates a trained AI model; and in which performing domain-adaptive pre-training of the AI model via self-supervised learning operations generates a trained domain-adapted AI model by fine-tuning the trained AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images.

(86) According to another embodiment, method **701-702** further includes: performing in-domain medical transfer learning for via the trained domain-adapted AI model by prioritizing all in-domain medical transfer learnings derived from the second set of training data which includes the plurality of medical images over any out-of-domain learnings derived from the pre-training of the AI model on the first set of training data generates a trained AI model.

(87) According to another embodiment of method **701-702**, prioritizing all in-domain medical transfer learnings is configured to improve performance of the trained domain-adapted AI model by reducing domain disparities between a source domain corresponding to the first set of training data and a target domain corresponding to the second set of training data which includes the plurality of medical images.

(88) According to another embodiment of method **701-702**, receiving the first set of training data which includes photographic images unrelated to a targeted medical diagnosis task includes receiving photographic images corresponding to a first domain type which lacks medical imaging data.

(89) According to another embodiment of method **701-702**, receiving the second set of training data which includes a plurality of medical images includes receiving medical imaging data

corresponding to a second domain type having at least a sub-set of the plurality of medical images correlated to the targeted medical diagnosis task.

(90) According to another embodiment of method **701-702**, receiving the first set of training data which includes photographic images unrelated to a targeted medical diagnosis task includes receiving a set of non-domain specific photographic images lacking any images correlated to the targeted medical diagnosis task.

(91) According to another embodiment, method **701-702** further includes: receiving, at the system, multiple medical imaging training data sets from multiple distinct sources; aggregating the multiple medical imaging training data sets into a single aggregated medical imaging dataset; and in which, receiving at the system, the second set of training data which includes the plurality of medical images derived from multiple distinct sources includes specifying the single aggregated medical imaging dataset as the second set of training data for performing the domain-adaptive pre-training of the AI model.

(92) According to another embodiment of method **701-702**, receiving the second set of training data which includes the plurality of medical images derived from multiple distinct sources includes training data incompatible with supervised learning for the AI model.

(93) According to another embodiment of method **701-702**, the plurality of medical images received with the second set of training data are configured with multiple inconsistent annotation and classification data including at least two or more of: inconsistent annotations across a sub-set of the plurality of medical images for the targeted medical diagnosis task; inconsistent annotations across a sub-set of the plurality of medical images for a common disease condition represented within the plurality of medical images; inconsistent annotations across a sub-set of the plurality of medical images for a common human anatomical feature classified within the plurality of medical images; inconsistent global level image annotations identifying disease conditions within an image and local level boxed-lesion labels identifying disease conditions within bounding boxes present within the plurality of medical images; inconsistent use of expert annotations for the plurality of medical images with at least a first portion of the plurality of medical images including expert annotations and at least a second portion of the plurality of medical images lacking any expert annotations; and inconsistent use of radiological reports associated with the plurality of medical images with at least a first portion of the plurality of medical images having radiological reports associated with them and at least a second portion of the plurality of medical images lacking any associated radiological reports.

(94) According to another embodiment of method **701-702**, performing the domain-adaptive pre-training of the AI model via the self-supervised learning operations, bridges a domain gap between photographic images from the first set of training data representing a first domain and medical images from the second set of training data representing a second domain; in which the self-supervised learning operations operate without requiring expert annotation of the medical images from the second set of training data which exhibit inconsistent or missing labeling and inconsistent or missing expert annotations.

(95) According to another embodiment of method **701-702**, performing the domain-adaptive pre-training of the AI model via self-supervised learning operations, includes: applying continual pre-training on a large-scale domain-specific dataset represented within the second set of training data having the plurality of medical images derived from the multiple distinct sources; in which the continual pre-training is performed via self-supervised Masked Image Modeling (MIM) learning by the AI model; and in which the self-supervised Masked Image Modeling (MIM) learning by the AI model mitigates over-fitting in the targeted medical diagnosis task.

(96) According to a particular embodiment, there is a non-transitory computer-readable storage media having instructions stored thereupon that, when executed by a system having at least a processor and a memory therein, the instructions cause the processor to execute instructions for systematically implementing self-supervised domain-adaptive pre-training via a transformer for use

with medical image classification, by performing operations including: receiving at the system, a first set of training data which includes photographic images unrelated to a targeted medical diagnosis task; receiving at the system, a second set of training data which includes a plurality of medical images derived from multiple distinct sources, in which the plurality of medical images are configured with multiple inconsistent annotation and classification data; executing instructions via the processor of the system for pre-training an AI model on the first set of training data which includes the photographic images by learning image classification from the photographic images within the first set of training data; executing instructions via the processor of the system for performing domain-adaptive pre-training of the AI model via self-supervised learning operations, in which the AI model previously trained on the first set of training data applies domain-adaptive learning to scale up data utilization of the second set of training data within the AI model's learned image classifications; generating a trained domain-adapted AI model by fine-tuning the AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images; outputting the trained domain-adapted AI model; and executing the trained domain-adapted AI model to generate a predicted medical diagnosis from an input image which forms no part of the first or second sets of training data.

(97) Benchmarking of Vision Transformers (ViTs):

(98) The recent success of Vision Transformers (“ViTs”) challenges the dominance of Convolutional Neural Networks (CNNs) for use with image classification tasks. The self-supervised learning (SSL) ViTs, in particular, produce outstanding results in terms of scalability and transferability for natural images. However, for medical images, there is no broad evaluation to benchmark the efficacy of emergent pre-training ViTs, much the methodologies for implementing such techniques.

(99) In accordance with the disclosed embodiments, the transferability of six (6) SSL ViTs and supervised ViTs were evaluated, both of which were pre-trained on ImageNet. On NIH ChestXray14, the models were fine-tuned and tested on the classification task. A comparison among models in different scales is described below (both small and base) as well as across different architectures (such as Vanilla ViT and hierarchical ViT).

(100) Result 1: A first result shows that regardless of the parameter initialization approach, the hierarchical ViT, specifically the Swin Transformer, achieves much better performance than Vanilla ViTs.

(101) Result 2: A second result shows that an SSL ViT, such as SimMIM with a patch masking-reconstruction proxy task in the Swin Transformer architecture, boosts performance even further.

(102) Result 3: And yet a third result shows that, following ImageNet initialization, continuing SimMIM pre-training on chest x-ray images after ImageNet initialization achieves higher accuracy than ResNet-50 at +1.3% mean AUC.

(103) FIG. 8 depicts Table 6 at element **801** illustrating performance of the disclosed methodology when compared with prior known techniques.

(104) As shown in FIG. 8, the performance of the disclosed methodology results in greater performance on the NIH ChestX-ray14 dataset when compared with other initialization techniques using a variety of models.

(105) Performance on the NIH ChestX-ray14 dataset of ViT/CNN models initialized by random weights, ImageNet weights, and six (6) SSL models pre-trained on ImageNet are presented by Table 6. Some of the SSL methods do not have the pre-trained models available for all architectures, resulting in the blank (e.g., “-”) entries.

(106) FIG. 9 depicts a chart showing a comparison of classification results (element **995**) on the NIH ChestX-ray14 dataset. In particular, there are depicted results for each of various SSL methodologies, including ViT Small at element **905**, ViT Base at element **910**, Swin Base at element **915**, and ResNet-50 at element **920**. The results depicted are measured against the AUC percentage (%) on the vertical axis, with the initialization techniques utilized identified on the

horizontal axis, including initialization from scratch at element **955**, ImageNet at element **960**, MoCo v3 at element **965**, BEiT at element **970**, DINO at element **975**, MoBY at element **980**, MAE at element **985**, and SimMIM at element **990**.

(107) As noted above, “Result 1” indicates that the Swin Transformer significantly outperforms the Vanilla ViT whereas “Result 2” indicates that the SimMIM with a patch masking-reconstruction proxy task outperforms other SSL methods.

(108) FIG. **10A** depicts Table 7 at element **1001** showing the performance of the disclosed methodology for different pre-training data sets.

(109) So as to evaluate the representation learning ability of the self-supervised ViT models on a massive chest X-ray data set, the evaluations included continued self-supervised training using the nearly 1-million chest X-ray images collected from various datasets.

(110) In particular, the methods **1070** evaluated included DINO+ViT Base at element **1071** and SimMIM+Swin Base at element **1072**, each evaluated using pre-training data **1075** including ImageNet-1k (element **1076**), AllX-rays (element **1077**), and ImageNet-1k+AllX-rays (element **1078**).

(111) FIG. **10B** depicts a chart **1002** showing the results of pre-training **1005** on out-domain and in-domain data.

(112) More specifically, SimMIM+Swin_B (element **1040**) results in greater performance across each of the combined ImageNet-1k+AllX-rays (element **1078**) data sets, as well as for each of the AllX-rays (element **1077**) data sets and ImageNet-1k (element **1076**) data sets individually.

(113) Consequently, “Result 3” indicates that continuing self-supervised pre-training on in-domain data (+AllX-rays) significantly improves performance in comparison to DINO+ViT_B/16 (element **1045**).

(114) FIG. **11** shows a diagrammatic representation of a system **1101** within which embodiments may operate, be installed, integrated, or configured. In accordance with one embodiment, there is a system **1101** having at least a processor **1190** and a memory **1195** therein to execute implementing application code **1194**. Such a system **1101** may communicatively interface with and cooperatively execute with the benefit of remote systems, such as a user device sending instructions and data, a user device to receive as an output from the system **1101** a semantics-enriched pre-trained model having a trained encoder-decoder structure with generic feature extraction and refinement operations as performed by the system **1101**, or systems within a networked or within a client-server environment, etc.

(115) According to the depicted embodiment, the system **1101**, includes the processor **1190** and the memory **1195** to execute instructions at the system **1101**. The system **1101** as depicted here is specifically customized and configured to implement the systematic benchmarking of user-specified vision transformers and user-specified datasets for use with chest x-ray classification, in which trained models may then be utilized for the processing of medical imaging.

(116) According to a particular embodiment, system **1101** is specially configured to execute instructions for systematically benchmarking vision transformers for use with chest x-ray classification, by performing operations including: receiving first user input **1127** specifying multiple vision transformers; receiving second user input **1128** specifying multiple training image datasets; generating a list **1129** of all possible combinations of the multiple vision transformers specified (e.g., via the model list combination generator at element **1150**) and the multiple training image datasets specified according to the first and second user inputs (elements **1127** and **1128**). Such a system **1101** is further configured for retrieving a pre-trained base model **1139** for each of the multiple vision transformers specified (e.g., via the base model configurator **1191**) and storing the pre-trained base models **1139** retrieved into the memory **1195** of the system **1101** for local execution. The system further is configured for retrieving the multiple training image datasets **1140** specified and storing the multiple training image datasets locally at the system **1101**. The system **1101** is further configured for initializing each of the pre-trained base models **1139** stored in

memory **1195** using a standardized dataset **1140**, such as ImageNet, with randomized initialization weights (e.g., via the transformer benchmarking platform **1145**) to generate initialized vision transformer models corresponding to each of the pre-trained base models stored in memory via model training **1147**. The system further executes Self-Supervised Learning (SSL) against each of the previously initialized vision transformer models (e.g., via SSL optimization component **1148**) using each of the multiple training image datasets corresponding to the list **1129** of all possible combinations previously generated to produce as output multiple SSL trained vision transformer models corresponding to the list of all possible combinations previously generated. The system further executes, via the processor of the system, each of the multiple SSL trained vision transformer models to generate image classification results **1142** as output from each of the multiple SSL trained vision transformer models; and then outputs from the system, a ranking (e.g., ranked list at element **1143**) of the image classification results **1142** generated as the output from each of the multiple SSL trained vision transformer models according to an area under the curve percentage calculation.

(117) Bus **1114** interfaces the various components of the system **1101** amongst each other, with any other peripheral(s) of the system **1101**, such as database storage system **1146**, and with external components such as external network elements, other machines, client devices, cloud computing services, etc. Communications may further include communicating with external devices via a network interface over a LAN, WAN, or the public Internet.

(118) According to yet another embodiment, the system **1101**, having a memory **1195** to store instructions and a processor **1190** to execute the instructions stored in the memory **1195**; further is specially configured to execute instructions via the processor for performing the following operations: receiving at the system **1101**, a first set of training data **1140** which includes photographic images unrelated to a targeted medical diagnosis task; receiving at the system **1101**, a second set of training data **1127** and **1128** (e.g., which may be user-specified) which includes a plurality of medical images derived from multiple distinct sources, wherein the plurality of medical images are configured with multiple inconsistent annotation and classification data. The system executes instructions via the processor **1190** of the system for pre-training (e.g., via model training block **1147**) an AI model **1137** on the first set of training data which includes the photographic images by learning image classification from the photographic images within the first set of training data. The system further executes instructions via the processor of the system for performing domain-adaptive pre-training of the AI model via self-supervised learning operations (e.g., via SSL optimization block **1148**), wherein the AI model previously trained on the first set of training data applies domain-adaptive learning to scale up data utilization of the second set of training data within the AI model's learned image classifications (e.g., image classification results **1142**). The system further generates a trained domain-adapted AI model by fine-tuning the AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images and outputs the trained domain-adapted AI model (e.g., as one of the benchmarked models). The system then executes the trained domain-adapted AI model **1144** to generate a predicted medical diagnosis from an input image which forms no part of the first or second sets of training data.

(119) FIGS. **12A** and **12B** depict a flow diagram illustrating a method **1201-1202** for systematically benchmarking vision transformers for use with chest x-ray classification, in accordance with disclosed embodiments. Method **1201-1202** may be performed by processing logic that may include hardware (e.g., circuitry, dedicated logic, programmable logic, microcode, etc.), software (e.g., instructions run on a processing device) to perform various operations such as designing, defining, retrieving, parsing, persisting, exposing, loading, executing, operating, receiving, generating, storing, maintaining, creating, returning, presenting, interfacing, communicating, transmitting, querying, processing, providing, determining, triggering, displaying, updating, sending, etc., in pursuance of the systems and methods as described herein. For example, the

system **1101** (see FIG. 11) and the machine **1301** (see FIG. 13) and the other supporting systems and components as described herein may implement the described methodologies. Some of the blocks and/or operations listed below are optional in accordance with certain embodiments. The numbering of the blocks presented is for the sake of clarity and is not intended to prescribe an order of operations in which the various blocks must occur.

(120) With reference to the method **1201-1202** depicted at FIGS. 12A and 12B, starting at block **1205**, there is a method performed by executing instructions via the processor of a specially configured system for systematically benchmarking vision transformers for use with chest x-ray classification. Such a system may be configured with at least a processor and a memory to execute specialized instructions which cause the system to perform the following operations:

(121) At block **1210**, processing logic receives a first user input specifying multiple vision transformers.

(122) At block **1215**, processing logic receives a second user input specifying multiple training image datasets.

(123) At block **1220**, processing logic generates a list of all possible combinations of the multiple vision transformers specified and the multiple training image datasets specified according to the first and second user inputs.

(124) At block **1225**, processing logic retrieves a pre-trained base model for each of the multiple vision transformers specified and storing the pre-trained base models retrieved in the memory of the system for local execution.

(125) Transitioning from FIG. 12A to the processing which continues at FIG. 12B, the processing of method **1201-1202** resumes at block **1230**.

(126) At block **1230**, processing logic retrieves the multiple training image datasets specified and storing the multiple training image datasets locally at the system.

(127) At block **1235**, processing logic initializes each of the pre-trained base models stored in memory using a standardized ImageNet dataset with randomized initialization weights to generate initialized vision transformer models corresponding to each of the pre-trained base models stored in memory.

(128) At block **1240**, processing logic executes Self-Supervised Learning (SSL) against each of the previously initialized vision transformer models using each of the multiple training image datasets corresponding to the list of all possible combinations previously generated to produce as output multiple SSL trained vision transformer models corresponding to the list of all possible combinations previously generated.

(129) At block **1245**, processing logic executes, via the processor of the system, each of the multiple SSL trained vision transformer models to generate image classification results as output from each of the multiple SSL trained vision transformer models.

(130) At block **1250**, processing logic outputs from the system, a ranking of the image classification results generated as the output from each of the multiple SSL trained vision transformer models according to an area under the curve percentage calculation.

(131) According to another embodiment of method **1201-1202**, the system implements a systematic benchmarking platform for user-selectable vision transformers.

(132) According to another embodiment of method **1201-1202**, the system performs benchmarking using chest X-ray classification by executing each of the multiple SSL trained vision transformer models and generating the image classification results as the output from each of the multiple SSL trained vision transformer models.

(133) According to another embodiment of method **1201-1202**, receiving the second user input specifying the multiple training image datasets includes receiving input specifying one or more datasets including medical images.

(134) According to another embodiment, method **1201-1202** further includes: receiving as third user input, multiple different Self-Supervised Learning (SSL) execution methods.

(135) According to another embodiment of method **1201-1202**, executing the Self-Supervised Learning against each of the previously initialized vision transformer models further includes executing the Self-Supervised Learning against each of the multiple different Self-Supervised Learning (SSL) execution methods as specified by the third user input for each of the previously initialized vision transformer models.

(136) According to another embodiment of method **1201-1202**, the ranking of the image classification results indicates transferability of each of the multiple SSL trained vision transformer models from processing of natural images to processing of medical images.

(137) According to another embodiment of method **1201-1202**, the ranking of the image classification results indicates scalability of each of the multiple SSL trained vision transformer models from processing of natural images to processing of medical images.

(138) According to another embodiment of method **1201-1202**, executing the Self-Supervised Learning against each of the previously initialized vision transformer models further includes continuing the Self-Supervised Learning until each respective ones of the previously initialized vision transformer models surpasses an accuracy threshold exceeding that of a standardized pre-trained 50-layer deep convolutional neural network.

(139) According to another embodiment of method **1201-1202**, the standardized pre-trained 50-layer deep convolutional neural network includes a pre-trained ResNet-50 AI model accessible to the system over a public Internet network interface.

(140) ResNet-50 is a convolutional neural network that is 50 layers deep. You can load a pre-trained version of the network trained on more than a million images from the ImageNet database. The pre-trained network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. Notably, however, the pre-trained ResNet-50 AI model, which is accessible to the disclosed platform over a public Internet network interface, was not trained using medical images.

(141) According to another embodiment of method **1201-1202**, executing the Self-Supervised Learning against each of the previously initialized vision transformer models further includes executing the Self-Supervised Learning supplemented with a patch masking-reconstruction proxy task as part of training the multiple SSL trained vision transformer models.

(142) According to a particular embodiment, there is a non-transitory computer-readable storage media having instructions stored thereupon that, when executed by a system having at least a processor and a memory therein, the instructions cause the processor to execute instructions for systematically benchmarking vision transformers for use with chest x-ray classification, by performing operations including: receiving first user input specifying multiple vision transformers; receiving second user input specifying multiple training image datasets; generating a list of all possible combinations of the multiple vision transformers specified and the multiple training image datasets specified according to the first and second user inputs; retrieving a pre-trained base model for each of the multiple vision transformers specified and storing the pre-trained base models retrieved in the memory of the system for local execution; retrieving the multiple training image datasets specified and storing the multiple training image datasets locally at the system; initializing each of the pre-trained base models stored in memory using a standardized ImageNet dataset with randomized initialization weights to generate initialized vision transformer models corresponding to each of the pre-trained base models stored in memory; executing Self-Supervised Learning (SSL) against each of the previously initialized vision transformer models using each of the multiple training image datasets corresponding to the list of all possible combinations previously generated to produce as output multiple SSL trained vision transformer models corresponding to the list of all possible combinations previously generated; executing, via the processor of the system, each of the multiple SSL trained vision transformer models to generate image classification results as output from each of the multiple SSL trained vision transformer models; and outputting from the system, a ranking of the image classification results generated as the output from each of

the multiple SSL trained vision transformer models according to an area under the curve percentage calculation.

(143) FIG. **13** illustrates a diagrammatic representation of a machine **1301** in the exemplary form of a computer system, in accordance with one embodiment, within which a set of instructions, for causing the machine/computer system to perform any one or more of the methodologies discussed herein, may be executed.

(144) In alternative embodiments, the machine may be connected (e.g., networked) to other machines in a Local Area Network (LAN), an intranet, an extranet, or the public Internet. The machine may operate in the capacity of a server or a client machine in a client-server network environment, as a peer machine in a peer-to-peer (or distributed) network environment, as a server or series of servers within an on-demand service environment. Certain embodiments of the machine may be in the form of a personal computer (PC), a tablet PC, a set-top box (STB), a Personal Digital Assistant (PDA), a cellular telephone, a web appliance, a server, a network router, switch or bridge, computing system, or any machine capable of executing a set of instructions (sequential or otherwise) that specify and mandate the specifically configured actions to be taken by that machine pursuant to stored instructions. Further, while only a single machine is illustrated, the term “machine” shall also be taken to include any collection of machines (e.g., computers) that individually or jointly execute a set (or multiple sets) of instructions to perform any one or more of the methodologies discussed herein.

(145) The exemplary machine **1301** includes a processor **1302**, a main memory **1304** (e.g., read-only memory (ROM), flash memory, dynamic random access memory (DRAM) such as synchronous DRAM (SDRAM) or Rambus DRAM (RDRAM), etc., static memory such as flash memory, static random access memory (SRAM), volatile but high-data rate RAM, etc.), and a secondary memory **1316** (e.g., a persistent storage device including hard disk drives and a persistent database and/or a multi-tenant database implementation), which communicate with each other via a bus **1330**. Main memory **1304** includes instructions for executing the various benchmarking techniques of the transformer benchmarking platform **1369** as described herein, including the execution components configured for receiving input specifying target models **1324**, the receiving input specifying target datasets **1323**, and execution components configured for retrieving a base model and base training (non-specified) data set which is utilized for model initialization. Further depicted are the SSL learning optimization instructions **1325** which are applied to previously initialized models, in support of the methodologies and techniques described herein. Main memory **1304** and its sub-elements are further operable in conjunction with processing logic **1326** and processor **1302** to perform the methodologies discussed herein.

(146) Processor **1302** represents one or more specialized and specifically configured processing devices such as a microprocessor, central processing unit, or the like. More particularly, the processor **1302** may be a complex instruction set computing (CISC) microprocessor, reduced instruction set computing (RISC) microprocessor, very long instruction word (VLIW) microprocessor, processor implementing other instruction sets, or processors implementing a combination of instruction sets. Processor **1302** may also be one or more special-purpose processing devices such as an application-specific integrated circuit (ASIC), a field programmable gate array (FPGA), a digital signal processor (DSP), network processor, or the like. Processor **1302** is configured to execute the processing logic **1326** for performing the operations and functionality which is discussed herein.

(147) The machine **1301** may further include a network interface card **1306**. The machine **1301** also may include a user interface **1310** (such as a video display unit, a liquid crystal display, etc.), an alphanumeric input device **1312** (e.g., a keyboard), a cursor control device **1313** (e.g., a mouse), and a signal generation device **1351** (e.g., an integrated speaker). The machine **1301** or computer system may further include peripheral device **1336** (e.g., wireless or wired communication devices, memory devices, storage devices, audio processing devices, video processing devices, etc.).

(148) The secondary memory **1316** may include a non-transitory machine-readable storage medium or a non-transitory computer readable storage medium or a non-transitory machine-accessible storage medium **1331** on which is stored one or more sets of instructions (e.g., software **1322**) embodying any one or more of the methodologies or functions described herein. The software **1322** may also reside, completely or at least partially, within the main memory **1304** and/or within the processor **1302** during execution thereof by the machine **1301**, the main memory **1304** and the processor **1302** also constituting machine-readable storage media. The software **1322** may further be transmitted or received over a network **1320** via the network interface card **1306**.

Recitation of the Numbered Embodiments

(149) In accordance with the disclosed embodiments, there is:

(150) 1. A system comprising: a memory to store instructions; a processor to execute the instructions stored in the memory; wherein the system is specially configured to execute instructions for systematically benchmarking vision transformers for use with chest x-ray classification, by performing operations including: receiving first user input specifying multiple vision transformers; receiving second user input specifying multiple training image datasets; generating a list of all possible combinations of the multiple vision transformers specified and the multiple training image datasets specified according to the first and second user inputs; retrieving a pre-trained base model for each of the multiple vision transformers specified and storing the pre-trained base models retrieved in the memory of the system for local execution; retrieving the multiple training image datasets specified and storing the multiple training image datasets locally at the system; initializing each of the pre-trained base models stored in memory using a standardized ImageNet dataset with randomized initialization weights to generate initialized vision transformer models corresponding to each of the pre-trained base models stored in memory; executing Self-Supervised Learning (SSL) against each of the previously initialized vision transformer models using each of the multiple training image datasets corresponding to the list of all possible combinations previously generated to produce as output multiple SSL trained vision transformer models corresponding to the list of all possible combinations previously generated; executing, via the processor of the system, each of the multiple SSL trained vision transformer models to generate image classification results as output from each of the multiple SSL trained vision transformer models; and outputting from the system, a ranking of the image classification results generated as the output from each of the multiple SSL trained vision transformer models according to an area under the curve percentage calculation.

(151) According to another embodiment of the system: wherein the system implements a systematic benchmarking platform for user-selectable vision transformers. According to another embodiment of the system: wherein the system performs benchmarking using chest X-ray classification by executing each of the multiple SSL trained vision transformer models and generating the image classification results as the output from each of the multiple SSL trained vision transformer models. According to another embodiment of the system: wherein receiving the second user input specifying the multiple training image datasets comprises receiving input specifying one or more datasets including medical images. According to another embodiment of the system: operations further include: receiving as third user input, multiple different Self-Supervised Learning (SSL) execution methods; and wherein executing the Self-Supervised Learning against each of the previously initialized vision transformer models further comprises executing the Self-Supervised Learning against each of the multiple different Self-Supervised Learning (SSL) execution methods as specified by the third user input for each of the previously initialized vision transformer models. According to another embodiment of the system: wherein the ranking of the image classification results indicates transferability of each of the multiple SSL trained vision transformer models from processing of natural images to processing of medical images. According to another embodiment of the system: wherein the ranking of the image classification results indicates scalability of each of the multiple SSL trained vision transformer models from processing

of natural images to processing of medical images. According to another embodiment of the system: wherein executing the Self-Supervised Learning against each of the previously initialized vision transformer models further comprises continuing the Self-Supervised Learning until each respective ones of the previously initialized vision transformer models surpasses an accuracy threshold exceeding that of a standardized pre-trained 50-layer deep convolutional neural network. According to another embodiment of the system: wherein the standardized pre-trained 50-layer deep convolutional neural network comprises a pre-trained ResNet-50 AI model accessible to the system over a public Internet network interface. According to another embodiment of the system: wherein executing the Self-Supervised Learning against each of the previously initialized vision transformer models further comprises executing the Self-Supervised Learning supplemented with a patch masking-reconstruction proxy task as part of training the multiple SSL trained vision transformer models.

(152) 2. According to yet another embodiment, there is a method performed by a system having at least a processor and a memory therein to execute instructions for systematically benchmarking vision transformers for use with chest x-ray classification, wherein the method comprises: receiving first user input specifying multiple vision transformers; receiving second user input specifying multiple training image datasets; generating a list of all possible combinations of the multiple vision transformers specified and the multiple training image datasets specified according to the first and second user inputs; retrieving a pre-trained base model for each of the multiple vision transformers specified and storing the pre-trained base models retrieved in the memory of the system for local execution; retrieving the multiple training image datasets specified and storing the multiple training image datasets locally at the system; initializing each of the pre-trained base models stored in memory using a standardized ImageNet dataset with randomized initialization weights to generate initialized vision transformer models corresponding to each of the pre-trained base models stored in memory; executing Self-Supervised Learning (SSL) against each of the previously initialized vision transformer models using each of the multiple training image datasets corresponding to the list of all possible combinations previously generated to produce as output multiple SSL trained vision transformer models corresponding to the list of all possible combinations previously generated; executing, via the processor of the system, each of the multiple SSL trained vision transformer models to generate image classification results as output from each of the multiple SSL trained vision transformer models; and outputting from the system, a ranking of the image classification results generated as the output from each of the multiple SSL trained vision transformer models according to an area under the curve percentage calculation.

(153) 3. According to yet another embodiment, there is a non-transitory computer readable storage media having instructions stored thereupon that, when executed by a system having at least a processor and a memory therein, the instructions cause the processor to execute instructions for systematically benchmarking vision transformers for use with chest x-ray classification, by performing operations including: receiving first user input specifying multiple vision transformers; receiving second user input specifying multiple training image datasets; generating a list of all possible combinations of the multiple vision transformers specified and the multiple training image datasets specified according to the first and second user inputs; retrieving a pre-trained base model for each of the multiple vision transformers specified and storing the pre-trained base models retrieved in the memory of the system for local execution; retrieving the multiple training image datasets specified and storing the multiple training image datasets locally at the system; initializing each of the pre-trained base models stored in memory using a standardized ImageNet dataset with randomized initialization weights to generate initialized vision transformer models corresponding to each of the pre-trained base models stored in memory; executing Self-Supervised Learning (SSL) against each of the previously initialized vision transformer models using each of the multiple training image datasets corresponding to the list of all possible combinations previously generated to produce as output multiple SSL trained vision transformer models corresponding to

the list of all possible combinations previously generated; executing, via the processor of the system, each of the multiple SSL trained vision transformer models to generate image classification results as output from each of the multiple SSL trained vision transformer models; and outputting from the system, a ranking of the image classification results generated as the output from each of the multiple SSL trained vision transformer models according to an area under the curve percentage calculation.

(154) 4. According to yet another embodiment, there is a system comprising: a memory to store instructions; a processor to execute the instructions stored in the memory; wherein the system is specially configured to execute instructions via the processor for performing the following operations: receiving at the system, a first set of training data which includes photographic images unrelated to a targeted medical diagnosis task; receiving at the system, a second set of training data which includes a plurality of medical images derived from multiple distinct sources, wherein the plurality of medical images are configured with multiple inconsistent annotation and classification data; executing instructions via the processor of the system for pre-training an AI model on the first set of training data which includes the photographic images by learning image classification from the photographic images within the first set of training data; executing instructions via the processor of the system for performing domain-adaptive pre-training of the AI model via self-supervised learning operations, wherein the AI model previously trained on the first set of training data applies domain-adaptive learning to scale up data utilization of the second set of training data within the AI model's learned image classifications; generating a trained domain-adapted AI model by fine-tuning the AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images; outputting the trained domain-adapted AI model; and executing the trained domain-adapted AI model to generate a predicted medical diagnosis from an input image which forms no part of the first or second sets of training data.

(155) According to another embodiment of the system: wherein pre-training the AI model on the first set of training data generates a trained AI model; and wherein performing domain-adaptive pre-training of the AI model via self-supervised learning operations generates a trained domain-adapted AI model by fine-tuning the trained AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images. According to another embodiment of the system, processing further includes: performing in-domain medical transfer learning for via the trained domain-adapted AI model by prioritizing all in-domain medical transfer learnings derived from the second set of training data which includes the plurality of medical images over any out-of-domain learnings derived from the pre-training of the AI model on the first set of training data generates a trained AI model. According to another embodiment of the system: wherein prioritizing all in-domain medical transfer learnings is configured to improve performance of the trained domain-adapted AI model by reducing domain disparities between a source domain corresponding to the first set of training data and a target domain corresponding to the second set of training data which includes the plurality of medical images. According to another embodiment of the system: wherein receiving the first set of training data which includes photographic images unrelated to a targeted medical diagnosis task comprises receiving photographic images corresponding to a first domain type which lacks medical imaging data. According to another embodiment of the system: wherein receiving the second set of training data which includes a plurality of medical images comprises receiving medical imaging data corresponding to a second domain type having at least a sub-set of the plurality of medical images correlated to the targeted medical diagnosis task. According to another embodiment of the system: wherein receiving the first set of training data which includes photographic images unrelated to a targeted medical diagnosis task comprises receiving a set of non-domain specific photographic images lacking any images correlated to the targeted medical diagnosis task. According to another embodiment of the system, processing further includes: receiving, at the system, multiple medical imaging training data sets from multiple distinct sources; aggregating the multiple medical imaging

training data sets into a single aggregated medical imaging dataset; and wherein, receiving at the system, the second set of training data which includes the plurality of medical images derived from multiple distinct sources comprises specifying the single aggregated medical imaging dataset as the second set of training data for performing the domain-adaptive pre-training of the AI model.

According to another embodiment of the system: wherein receiving the second set of training data which includes the plurality of medical images derived from multiple distinct sources includes training data incompatible with supervised learning for the AI model.

According to another embodiment of the system: wherein the plurality of medical images received with the second set of training data are configured with multiple inconsistent annotation and classification data including at least two or more of: inconsistent annotations across a sub-set of the plurality of medical images for the targeted medical diagnosis task; inconsistent annotations across a sub-set of the plurality of medical images for a common disease condition represented within the plurality of medical images; inconsistent annotations across a sub-set of the plurality of medical images for a common human anatomical feature classified within the plurality of medical images; inconsistent global level image annotations identifying disease conditions within an image and local level boxed-lesion labels identifying disease conditions within bounding boxes present within the plurality of medical images; inconsistent use of expert annotations for the plurality of medical images with at least a first portion of the plurality of medical images including expert annotations and at least a second portion of the plurality of medical images lacking any expert annotations; and inconsistent use of radiological reports associated with the plurality of medical images with at least a first portion of the plurality of medical images having radiological reports associated with them and at least a second portion of the plurality of medical images lacking any associated radiological reports.

According to another embodiment of the system: wherein performing the domain-adaptive pre-training of the AI model via the self-supervised learning operations, bridges a domain gap between photographic images from the first set of training data representing a first domain and medical images from the second set of training data representing a second domain; wherein the self-supervised learning operations operate without requiring expert annotation of the medical images from the second set of training data which exhibit inconsistent or missing labeling and inconsistent or missing expert annotations.

According to another embodiment of the system: wherein performing the domain-adaptive pre-training of the AI model via self-supervised learning operations, comprises: applying continual pre-training on a large-scale domain-specific dataset represented within the second set of training data having the plurality of medical images derived from the multiple distinct sources; wherein the continual pre-training is performed via self-supervised Masked Image Modeling (MIM) learning by the AI model; and wherein the self-supervised Masked Image Modeling (MIM) learning by the AI model mitigates over-fitting in the targeted medical diagnosis task.

(156) 5. According to yet another embodiment, there is a computer-implemented method performed by a system having at least a processor and a memory therein for executing instructions, wherein the computer-implemented method comprises: receiving at the system, a first set of training data which includes photographic images unrelated to a targeted medical diagnosis task; receiving at the system, a second set of training data which includes a plurality of medical images derived from multiple distinct sources, wherein the plurality of medical images are configured with multiple inconsistent annotation and classification data; executing instructions via the processor of the system for pre-training an AI model on the first set of training data which includes the photographic images by learning image classification from the photographic images within the first set of training data; executing instructions via the processor of the system for performing domain-adaptive pre-training of the AI model via self-supervised learning operations, wherein the AI model previously trained on the first set of training data applies domain-adaptive learning to scale up data utilization of the second set of training data within the AI model's learned image classifications; generating a trained domain-adapted AI model by fine-tuning the AI model against the targeted

medical diagnosis task using the second set of training data which includes the plurality of medical images; outputting the trained domain-adapted AI model; and executing the trained domain-adapted AI model to generate a predicted medical diagnosis from an input image which forms no part of the first or second sets of training data.

(157) 6. According to yet another embodiment, there is a non-transitory computer readable storage media having instructions stored thereupon that, when executed by a system having at least a processor and a memory therein, the instructions cause the processor to perform operations including: receiving at the system, a first set of training data which includes photographic images unrelated to a targeted medical diagnosis task; receiving at the system, a second set of training data which includes a plurality of medical images derived from multiple distinct sources, wherein the plurality of medical images are configured with multiple inconsistent annotation and classification data; executing instructions via the processor of the system for pre-training an AI model on the first set of training data which includes the photographic images by learning image classification from the photographic images within the first set of training data; executing instructions via the processor of the system for performing domain-adaptive pre-training of the AI model via self-supervised learning operations, wherein the AI model previously trained on the first set of training data applies domain-adaptive learning to scale up data utilization of the second set of training data within the AI model's learned image classifications; generating a trained domain-adapted AI model by fine-tuning the AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images; outputting the trained domain-adapted AI model; and executing the trained domain-adapted AI model to generate a predicted medical diagnosis from an input image which forms no part of the first or second sets of training data.

(158) While the subject matter disclosed herein has been described by way of example and in terms of the specific embodiments, it is to be understood that the claimed embodiments are not limited to the explicitly enumerated embodiments disclosed. To the contrary, the disclosure is intended to cover various modifications and similar arrangements as are apparent to those skilled in the art. Therefore, the scope of the appended claims is to be accorded the broadest interpretation so as to encompass all such modifications and similar arrangements. It is to be understood that the above description is intended to be illustrative, and not restrictive. Many other embodiments will be apparent to those of skill in the art upon reading and understanding the above description. The scope of the disclosed subject matter is therefore to be determined in reference to the appended claims, along with the full scope of equivalents to which such claims are entitled.

Claims

1. A system comprising: a memory to store instructions; a processor to execute the instructions stored in the memory; wherein the system is specially configured to execute instructions via the processor for performing the following operations: receiving at the system, a first set of training data which includes photographic images unrelated to a targeted medical diagnosis task; receiving at the system, a second set of training data which includes a plurality of medical images derived from multiple distinct sources, wherein the plurality of medical images are configured with multiple inconsistent annotation and classification data; executing instructions via the processor of the system for pre-training an AI model on the first set of training data which includes the photographic images by learning image classification from the photographic images within the first set of training data; executing instructions via the processor of the system for performing domain-adaptive pre-training of the AI model via self-supervised learning operations, wherein the AI model previously trained on the first set of training data applies domain-adaptive learning to scale up data utilization of the second set of training data within the AI model's learned image classifications; generating a trained domain-adapted AI model by fine-tuning the AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical

images; outputting the trained domain-adapted AI model; and executing the trained domain-adapted AI model to generate a predicted medical diagnosis from an input image which forms no part of the first or second sets of training data.

2. The system of claim 1: wherein pre-training the AI model on the first set of training data generates a trained AI model; and wherein performing domain-adaptive pre-training of the AI model via self-supervised learning operations generates a trained domain-adapted AI model by fine-tuning the trained AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images.

3. The system of claim 1, further comprising: performing in-domain medical transfer learning for via the trained domain-adapted AI model by prioritizing all in-domain medical transfer learnings derived from the second set of training data which includes the plurality of medical images over any out-of-domain learnings derived from the pre-training of the AI model on the first set of training data generates a trained AI model.

4. The system of claim 3, wherein prioritizing all in-domain medical transfer learnings is configured to improve performance of the trained domain-adapted AI model by reducing domain disparities between a source domain corresponding to the first set of training data and a target domain corresponding to the second set of training data which includes the plurality of medical images.

5. The system of claim 1, wherein receiving the first set of training data which includes photographic images unrelated to a targeted medical diagnosis task comprises receiving photographic images corresponding to a first domain type which lacks medical imaging data.

6. The system of claim 1, wherein receiving the second set of training data which includes a plurality of medical images comprises receiving medical imaging data corresponding to a second domain type having at least a sub-set of the plurality of medical images correlated to the targeted medical diagnosis task.

7. The system of claim 1, wherein receiving the first set of training data which includes photographic images unrelated to a targeted medical diagnosis task comprises receiving a set of non-domain specific photographic images lacking any images correlated to the targeted medical diagnosis task.

8. The system of claim 1, further comprising: receiving, at the system, multiple medical imaging training data sets from multiple distinct sources; aggregating the multiple medical imaging training data sets into a single aggregated medical imaging dataset; and wherein, receiving at the system, the second set of training data which includes the plurality of medical images derived from multiple distinct sources comprises specifying the single aggregated medical imaging dataset as the second set of training data for performing the domain-adaptive pre-training of the AI model.

9. The system of claim 1, wherein receiving the second set of training data which includes the plurality of medical images derived from multiple distinct sources includes training data incompatible with supervised learning for the AI model.

10. The system of claim 1, wherein the plurality of medical images received with the second set of training data are configured with multiple inconsistent annotation and classification data including at least two or more of: inconsistent annotations across a sub-set of the plurality of medical images for the targeted medical diagnosis task; inconsistent annotations across a sub-set of the plurality of medical images for a common disease condition represented within the plurality of medical images; inconsistent annotations across a sub-set of the plurality of medical images for a common human anatomical feature classified within the plurality of medical images; inconsistent global level image annotations identifying disease conditions within an image and local level boxed-lesion labels identifying disease conditions within bounding boxes present within the plurality of medical images; inconsistent use of expert annotations for the plurality of medical images with at least a first portion of the plurality of medical images including expert annotations and at least a second portion of the plurality of medical images lacking any expert annotations; and inconsistent use of

radiological reports associated with the plurality of medical images with at least a first portion of the plurality of medical images having radiological reports associated with them and at least a second portion of the plurality of medical images lacking any associated radiological reports.

11. The system of claim 1, wherein performing the domain-adaptive pre-training of the AI model via the self-supervised learning operations, bridges a domain gap between photographic images from the first set of training data representing a first domain and medical images from the second set of training data representing a second domain; wherein the self-supervised learning operations operate without requiring expert annotation of the medical images from the second set of training data which exhibit inconsistent or missing labeling and inconsistent or missing expert annotations.

12. The system of claim 1, wherein performing the domain-adaptive pre-training of the AI model via self-supervised learning operations, comprises: applying continual pre-training on a large-scale domain-specific dataset represented within the second set of training data having the plurality of medical images derived from the multiple distinct sources; wherein the continual pre-training is performed via self-supervised Masked Image Modeling (MIM) learning by the AI model; and wherein the self-supervised Masked Image Modeling (MIM) learning by the AI model mitigates over-fitting in the targeted medical diagnosis task.

13. A computer-implemented method performed by a system having at least a processor and a memory therein for executing instructions, wherein the computer-implemented method comprises: receiving at the system, a first set of training data which includes photographic images unrelated to a targeted medical diagnosis task; receiving at the system, a second set of training data which includes a plurality of medical images derived from multiple distinct sources, wherein the plurality of medical images are configured with multiple inconsistent annotation and classification data; executing instructions via the processor of the system for pre-training an AI model on the first set of training data which includes the photographic images by learning image classification from the photographic images within the first set of training data; executing instructions via the processor of the system for performing domain-adaptive pre-training of the AI model via self-supervised learning operations, wherein the AI model previously trained on the first set of training data applies domain-adaptive learning to scale up data utilization of the second set of training data within the AI model's learned image classifications; generating a trained domain-adapted AI model by fine-tuning the AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images; outputting the trained domain-adapted AI model; and executing the trained domain-adapted AI model to generate a predicted medical diagnosis from an input image which forms no part of the first or second sets of training data.

14. The computer-implemented method of claim 13: wherein pre-training the AI model on the first set of training data generates a trained AI model; and wherein performing domain-adaptive pre-training of the AI model via self-supervised learning operations generates a trained domain-adapted AI model by fine-tuning the trained AI model against the targeted medical diagnosis task using the second set of training data which includes the plurality of medical images.

15. The computer-implemented method of claim 13, further comprising: performing in-domain medical transfer learning for via the trained domain-adapted AI model by prioritizing all in-domain medical transfer learnings derived from the second set of training data which includes the plurality of medical images over any out-of-domain learnings derived from the pre-training of the AI model on the first set of training data generates a trained AI model; and wherein prioritizing all in-domain medical transfer learnings is configured to improve performance of the trained domain-adapted AI model by reducing domain disparities between a source domain corresponding to the first set of training data and a target domain corresponding to the second set of training data which includes the plurality of medical images.

16. The computer-implemented method of claim 13, wherein receiving the first set of training data which includes photographic images unrelated to a targeted medical diagnosis task comprises receiving photographic images corresponding to a first domain type which lacks medical imaging

data; and wherein receiving the second set of training data which includes a plurality of medical images comprises receiving medical imaging data corresponding to a second domain type having at least a sub-set of the plurality of medical images correlated to the targeted medical diagnosis task.

17. The computer-implemented method of claim 13, wherein receiving the first set of training data which includes photographic images unrelated to a targeted medical diagnosis task comprises receiving a set of non-domain specific photographic images lacking any images correlated to the targeted medical diagnosis task.

18. The computer-implemented method of claim 13, further comprising: receiving, at the system, multiple medical imaging training data sets from multiple distinct sources; aggregating the multiple medical imaging training data sets into a single aggregated medical imaging dataset; and wherein, receiving at the system, the second set of training data which includes the plurality of medical images derived from multiple distinct sources comprises specifying the single aggregated medical imaging dataset as the second set of training data for performing the domain-adaptive pre-training of the AI model.

19. The computer-implemented method of claim 13, wherein the plurality of medical images received with the second set of training data are configured with multiple inconsistent annotation and classification data including at least two or more of: inconsistent annotations across a sub-set of the plurality of medical images for the targeted medical diagnosis task; inconsistent annotations across a sub-set of the plurality of medical images for a common disease condition represented within the plurality of medical images; inconsistent annotations across a sub-set of the plurality of medical images for a common human anatomical feature classified within the plurality of medical images; inconsistent global level image annotations identifying disease conditions within an image and local level boxed-lesion labels identifying disease conditions within bounding boxes present within the plurality of medical images; inconsistent use of expert annotations for the plurality of medical images with at least a first portion of the plurality of medical images including expert annotations and at least a second portion of the plurality of medical images lacking any expert annotations; and inconsistent use of radiological reports associated with the plurality of medical images with at least a first portion of the plurality of medical images having radiological reports associated with them and at least a second portion of the plurality of medical images lacking any associated radiological reports.

20. A system comprising: a memory to store instructions; a processor to execute the instructions stored in the memory; wherein the system is specially configured to execute instructions for systematically benchmarking vision transformers for use with chest x-ray classification, by performing operations including: receiving first user input specifying multiple vision transformers; receiving second user input specifying multiple training image datasets; generating a list of all possible combinations of the multiple vision transformers specified and the multiple training image datasets specified according to the first and second user inputs; retrieving a pre-trained base model for each of the multiple vision transformers specified and storing the pre-trained base models retrieved in the memory of the system for local execution; retrieving the multiple training image datasets specified and storing the multiple training image datasets locally at the system; initializing each of the pre-trained base models stored in memory using a standardized ImageNet dataset with randomized initialization weights to generate initialized vision transformer models corresponding to each of the pre-trained base models stored in memory; executing Self-Supervised Learning (SSL) against each of the previously initialized vision transformer models using each of the multiple training image datasets corresponding to the list of all possible combinations previously generated to produce as output multiple SSL trained vision transformer models corresponding to the list of all possible combinations previously generated; executing, via the processor of the system, each of the multiple SSL trained vision transformer models to generate image classification results as output from each of the multiple SSL trained vision transformer models; and outputting from the system, a ranking of the image classification results generated as the output from each of

the multiple SSL trained vision transformer models according to an area under the curve percentage calculation.
