LIGHT DIFFUSION SHEET, BACK-LIGHT UNIT, LIQUID CRYSTAL DISPLAY DEVICE, INFORMATION APPARATUS, AND METHOD FOR MANUFACTURING BACK-LIGHT UNIT

Abstract

A light diffusion sheet is incorporated in a backlight unit using a plurality of light sources arranged in a two-dimensional matrix. The light diffusion sheet has surfaces, on at least one of which a plurality of recesses having a substantially inverted quadrangular pyramid shape are arranged in a two-dimensional matrix. An intersecting angle between an arrangement direction of the plurality of recesses and an arrangement direction of the plurality of light sources is 30° or more and 60° or less.

Background/Summary

CROSS REFERENCE TO RELATED APPLICATIONS [0001] This application is a continuation of U.S. application Ser. No. 18/825,724, filed Sep. 5, 2024, which is a continuation of International Application No. PCT/JP2022/041405, filed Nov. 7, 2022, which claims priority to and the benefit of Japanese Application No. 2022-035936, filed Mar. 9, 2022; the contents of all of which are hereby incorporated by reference in their entirety.

BACKGROUND

[0002] The present disclosure relates to a light diffusion sheet, a backlight unit, a liquid crystal display device, an information apparatus, and a method for manufacturing the backlight unit.

[0003] Liquid crystal display devices (hereinafter referred to as liquid crystal displays in some cases) have been widely used as display devices for various information apparatuses such as smartphones and tablet terminals. A major type of a backlight of a liquid crystal display is an edge light type in which light sources are arranged near a side surface of a liquid crystal panel.

[0004] When the direct-type backlight is adopted, a light diffusion sheet is used to diffuse light emitted from a light source such as a light emitting diode (LED) to improve uniformity of luminance and chromaticity over the entire screen (e.g., see Japanese Unexamined Patent Publication No. 2011-129277).

[0005] A direct-type backlight unit for a thin display such as a laptop computer or a tablet computer is used with, e.g., a light diffusion sheet having two-dimensionally arranged recesses having an inverted pyramid shape.

BRIEF SUMMARY

[0006] However, traditional light diffusion sheets have not yet yielded sufficient luminance uniformity.

[0007] It is an object of the present disclosure to provide a light diffusion sheet that enables improvement in the luminance uniformity.

[0008] To achieve the above object, the light diffusion sheet of the present disclosure is a light diffusion sheet incorporated in a backlight unit using a plurality of light sources arranged in a two-dimensional matrix, wherein the light diffusion sheet has surfaces, on at least one of which a plurality of recesses having a substantially inverted quadrangular pyramid shape are arranged in a two-dimensional matrix, and an intersecting angle between an arrangement direction of the plurality of recesses and an arrangement direction of the plurality of light sources is 30° or more and 60° or less.

[0009] According to the light diffusion sheet of the present disclosure, the intersecting angle between the arrangement direction of the recesses and the arrangement direction of the light sources is set to 30° or more and 60° or less. Thus, the intensity of light emitted from the light diffusion sheet can be increased in the diagonal direction of the light source arrangement where the distance between the light sources is long and the luminance is likely to decrease (the direction inclined by 45° with respect to the arrangement direction of the light source). Therefore, the luminance uniformity can be improved.

[0010] In the present disclosure, the expression “the plurality of light sources are arranged in a two-dimensional matrix” encompasses “light source groups each consisting of several small light

sources are arranged in a two-dimensional matrix,” and in this case, the small light sources themselves constituting each light source group may not be arranged in a two-dimensional matrix. [0011] In the light diffusion sheet of the present disclosure, if the intersecting angle is 35° or more and 55° or less, and more preferably 40° or more and 50° or less, the luminance uniformity can be further improved.

[0012] In the light diffusion sheet of the present disclosure, if the recesses are provided on the light emitting surface, the intensity of light emitted from the light diffusion sheet can be easily increased in the diagonal direction of the light source arrangement.

[0013] A backlight unit of the present disclosure is a backlight unit incorporated in a liquid crystal display device and leading light emitted from a plurality of light sources arranged in a two-dimensional matrix to a display screen. The backlight unit includes the light diffusion sheet of the present disclosure provided between the display screen and the plurality of light sources.

[0014] The backlight unit of the present disclosure includes the light diffusion sheet of the present disclosure, and thus the luminance uniformity can be improved.

[0015] If, in the backlight unit of the present disclosure, the light diffusion sheet includes a plurality of the light diffusion sheets, the plurality of the light diffusion sheets diffuse light repeatedly, and thus the luminance uniformity can be further improved.

[0016] The backlight unit of the present disclosure may further include a color conversion sheet provided between the display screen and the plurality of light sources and configured to convert a wavelength of light emitted from the plurality of light sources. Accordingly, even when the light sources are light sources other than white light sources, the backlight unit can be configured.

[0017] The backlight unit of the present disclosure may include a luminance enhancing sheet provided between the light diffusion sheet and the display screen and configured to enhance luminance of light emitted from the plurality of light sources. Accordingly, the luminance uniformity can be improved whereas the luminance can be increased.

[0018] In the backlight unit of the present disclosure, the plurality of light sources may be arranged on a reflection sheet provided opposite to the display screen when viewed from the light diffusion sheet. This causes multiple reflections between the light diffusion sheet and the reflection sheet thus causing further light diffusion, and thus the luminance uniformity is further improved.

[0019] A liquid crystal display device of the present disclosure includes the backlight unit of the present disclosure and a liquid crystal display panel.

[0020] The liquid crystal display device of the present disclosure includes the backlight unit of the present disclosure, and thus the luminance uniformity can be improved.

[0021] An information apparatus of the present disclosure includes the liquid crystal display device of the present disclosure.

[0022] The information apparatus of the present disclosure includes the liquid crystal display device of the present disclosure, and thus the luminance uniformity can be improved.

[0023] A method of the present disclosure for manufacturing a backlight unit is a method for manufacturing a backlight unit incorporated in a liquid crystal display device and leading light emitted from a plurality of light sources arranged in a two-dimensional matrix to a display screen, comprising: arranging the plurality of light sources; and arranging a light diffusion sheet having surfaces, on at least one of which a plurality of recesses having a substantially inverted quadrangular pyramid shape are arranged in a two-dimensional matrix, wherein the plurality of light sources and the light diffusion sheet are arranged so that an intersecting angle between an arrangement direction of the plurality of recesses and an arrangement direction of the plurality of light sources is 30° or more and 60° or less.

[0024] According to the method of the present disclosure for manufacturing the backlight unit, the intersecting angle between the arrangement direction of the recesses of the light diffusion sheet and the arrangement direction of the light sources is set to 30° or more and 60° or less. Thus, the intensity of light emitted from the light diffusion sheet can be increased in the diagonal direction of

the light source arrangement where the distance between the light sources is long and the luminance is likely to decrease (the direction inclined by 45° with respect to the arrangement direction of the light source). Therefore, the luminance uniformity can be improved.
[0025] The present disclosure can provide a light diffusion sheet that enables improvement in the luminance uniformity.

Description

BRIEF DESCRIPTION OF THE FIGURES

[0026] FIG. 1 is a cross-sectional view of a liquid crystal display device including a backlight unit of an embodiment.

[0027] FIG. 2 is a cross-sectional view of a backlight unit incorporating a light diffusion sheet of the embodiment.

[0028] FIG. 3 is a plan view showing an exemplary arrangement of light sources in the backlight unit shown in FIG. 2.

[0029] FIG. 4 is a cross-sectional view of the light diffusion sheet of the embodiment.

[0030] FIG. 5 is a perspective view of the light diffusion sheet of the embodiment.

[0031] FIG. 6 is a plan view showing an exemplary arrangement of recesses in the light diffusion sheet of the embodiment.

[0032] FIG. 7 is a diagram showing a relationship between an arrangement angle of the light diffusion sheet of the embodiment and an arrangement angle of a prism sheet.

[0033] FIG. 8 shows change in the luminance uniformity with variation in the arrangement angle of the light diffusion sheet of the embodiment.

[0034] FIG. 9 shows change in the luminance uniformity with variation in the arrangement angle of the prism sheet with the arrangement angle of the light diffusion sheet of the embodiment being fixed to 45° and 0°.

[0035] FIG. 10 shows change in the luminance uniformity with variation in the arrangement angle of the light diffusion sheet of the embodiment together with variation in the arrangement angle of the prism sheet.

[0036] FIG. 11 shows the luminance uniformity where the light diffusion sheet of the embodiment includes three light diffusion sheets which have various arrangement angles.

DETAILED DESCRIPTION OF VARIOUS EMBODIMENTS

Embodiment

[0037] A light diffusion sheet, a backlight unit, a liquid crystal display device, an information apparatus, and a method for manufacturing the backlight unit of an embodiment will be described below with reference to the drawings. Note that the scope of the present disclosure is not limited to the following embodiments, and may be altered in any way within the scope of the technical concept of the present disclosure.

<Liquid Crystal Display Device>

[0038] As shown in FIG. 1, a liquid crystal display device **50** includes a liquid crystal display panel **5**, a first polarizing plate **6** attached to a lower surface of the liquid crystal display panel **5**, a second polarizing plate **7** attached to an upper surface of the liquid crystal display panel **5**, and a backlight unit **40** provided on a back surface side of the liquid crystal display panel **5** with the first polarizing plate **6** sandwiched therebetween.

[0039] The liquid crystal display panel **5** includes a TFT substrate **1** and a CF substrate **2** provided so as to face each other, a liquid crystal layer **3** provided between the TFT substrate **1** and the CF substrate **2**, and a sealing (not shown) provided in a frame shape to seal the liquid crystal layer **3** between the TFT substrate **1** and the CF substrate **2**.

[0040] The shape of a display screen **50a** of the liquid crystal display device **50** viewed from the

front (the top in FIG. 1) is basically a rectangle or a square. Alternatively, the shape may be any shape such as a rectangle with rounded corners, an oval, a circle, a trapezoid, or the shape of an instrument panel of an automobile.

[0041] The liquid crystal display device **50** applies a voltage of a predetermined magnitude to the liquid crystal layer **3** in sub-pixels corresponding to pixel electrodes, thereby changing the alignment state of the liquid crystal layer **3**. This adjusts the transmittance of light incident from the backlight unit **40** through the first polarizing plate **6**. The light whose transmittance is adjusted is emitted through the second polarizing plate **7** to display an image.

[0042] The liquid crystal display device **50** of this embodiment is used as a display apparatus to be built in various information apparatuses (e.g., in-vehicle devices such as car navigation systems; personal computers; mobile phones; portable information equipment such as laptops and tablet computers; portable game machines; copying machines; ticket vending machines; automated teller machines; and the like).

[0043] The TFT substrate **1** includes, e.g., a plurality of TFTs arranged in a matrix on a glass substrate, an interlayer insulating film arranged in such a manner as to cover the TFTs, a plurality of pixel electrodes arranged in a matrix on the interlayer insulating film and connected to their respective TFTs, and an alignment film arranged in such a manner as to cover the pixel electrodes. The CF substrate **2** includes, e.g., a black matrix arranged in a lattice manner on a glass substrate, a color filter including a red layer, a green layer, and a blue layer arranged between lattices of the black matrix, a common electrode arranged in such a manner as to cover the black matrix and the color filter, and an alignment film arranged in such a manner as to cover the common electrode. The liquid crystal layer **3** is made of, e.g., a nematic liquid crystal material containing liquid crystal molecules having electro-optical characteristics. The first polarizing plate **6** and the second polarizing plate **7** each includes, e.g., a polarizer layer having a polarization axis in one direction, and a pair of protective layers arranged in such a manner as to sandwich the polarizer layer.

<Backlight Unit>

[0044] As shown in FIG. 2, the backlight unit **40** includes a reflection sheet **41**, a plurality of light sources **42** arranged two-dimensionally on the reflection sheet **41**, a light diffusion sheet **43** provided above the plurality of light sources **42**, and a luminance enhancing sheet **48** provided above the light diffusion sheet **43** (or between the display screen **50a** and the light diffusion sheet **43**). In FIG. 2, the backlight unit **40** includes a color conversion sheet **46** arranged between the light sources **42** and the light diffusion sheet **43**, and an upper light diffusion sheet **47** arranged above the luminance enhancing sheet **48** (or between the display screen **50a** and the luminance enhancing sheet **48**). The light diffusion sheet **43** will be described in detail later.

[Reflection Sheet]

[0045] The reflection sheet **41** is formed of, for example, a white polyethylene terephthalate resin film, a silver-deposited film, or the like.

[Light Source]

[0046] The type of the light sources **42** is not particularly limited. For example, an LED element, a laser element, or the like may be adopted, and an LED element may be adopted for the sake of costs, productivity, and the like. In order to adjust light emission angle characteristics of the LED element serving as the light source **42**, a lens may be attached to the LED element. The light sources **42** may have a rectangular shape in a plan view, each side of which may be 10 μm or more (preferably 50 μm or more) and 10 mm or less (preferably 5 mm or less). The number of the light sources **42** is not limited, but preferably, to be distributed, the plurality of light sources **42** may be arranged regularly on the reflection sheet **41**. The “arranged regularly” means arrangement with a certain regularity. For example, the light sources **42** may be arranged at equal intervals. If the light sources **42** are arranged at equal intervals, the distance between the centers of two adjacent small light sources **42** may be 0.5 mm or more (preferably 2 mm or more) and 20 mm or less.

[0047] In this embodiment, as shown in FIG. 3 for example, the plurality of light sources **42**

consisting of LED elements are arranged at regular intervals in a two-dimensional array with the X direction and the Y direction. In other words, the plurality of light sources **42** are arranged along the two directions (X direction and Y direction) perpendicular to each other. In this embodiment, the light sources **42** are blue light sources. The blue light sources may emit light of $x < 0.24$ and $y < 0.18$ in the CIE1931 color coordinates, for example. The light sources **42** may be white light sources. The white light sources may be configured by an LED element having the peak wavelength in a blue region, an LED element having the peak wavelength in a green region, and an LED element having the peak wavelength in a red region, and may emit light of $0.24 < x < 0.42$ and $0.18 < y < 0.48$ in the CIE1931 color coordinates, for example.

[Color Conversion Sheet]

[0048] The color conversion sheet **46** is a wavelength conversion sheet for converting light emitted from the light source **42** (e.g., a blue light source) into light having a wavelength of a certain color (e.g., green or red) as a peak wavelength. The color conversion sheet **46** converts, e.g., blue light with a wavelength of 450 nm into green light with a wavelength of 540 nm and red light with a wavelength of 650 nm. In this case, when the light source **42** emitting blue light with a wavelength of 450 nm is used, the color conversion sheet **46** partially converts blue light into green light and red light, and thus the light transmitted through the color conversion sheet **46** becomes white light. The color conversion sheet **46** may be, e.g., a quantum dot (QD) sheet, a fluorescent sheet, or the like.

[0049] When the light sources **42** are white light sources, the color conversion sheet **46** may be unnecessary. The arrangement of the color conversion sheet **46** is not particularly limited as long as it is arranged between the light source **42** and the luminance enhancing sheet **48** described later. For example, the color conversion sheet **46** may be arranged between the light diffusion sheet **43** and the luminance enhancing sheet **48**.

[Luminance Enhancing Sheet]

[0050] The luminance enhancing sheet **47** has a structure having a lower prism sheet **44** and an upper prism sheet **45** layered in sequence from the side closer to the light source **42**. The prism sheets **44** and **45**, through which the light rays need to pass, are formed mainly of a transparent (e.g., colorless and transparent) synthetic resin. The prism sheets **44** and **45** may be integrated. The lower prism sheet **44** includes a base material layer **44a** and an array of a plurality of prism projections **44b** stacked on the surface of the base material layer **44a**. Similarly, the upper prism sheet **45** includes a base material layer **45a** and an array of a plurality of prism projections **45b** stacked on the surface of the base material layer **45a**. The prism projections **44b** and **45b** are stacked in a stripe pattern on the surfaces of the base material layers **44a** and **45a**, respectively. The prism projections **44b** and **45b** are triangular prisms and have back surfaces that are in contact with the surfaces of the base material layers **44a** and **45a**, respectively. The extending direction of the prism projections **44b** and the extending direction of the prism projections **45b** are perpendicular to each other. Accordingly, light rays incident from the light diffusion sheet **43** can be refracted in the normal direction by the lower prism sheet **44**, and light rays emitted from the lower prism sheet **44** can be further refracted by the upper prism sheet **45** in a direction substantially perpendicular to the display screen **50a**.

[0051] The lower limit of the thickness of the prism sheets **44** and **45** (the height from the back surface of the base material layer **44a** and **45a** to the apex of the prism projections **44b** and **45b**) may be, e.g., approximately 50 μm , and more preferably approximately 100 μm . The upper limit of the thickness of the prism sheets **44** and **45** may be, e.g., approximately 200 μm , and more preferably approximately 180 μm . The lower limit of the pitch of the prism projections **44b** and **45b** in the prism sheets **44** and **45** may be, e.g., approximately 20 μm , and more preferably approximately 25 μm . The upper limit of the pitch of the prism projections **44b** and **45b** in the prism sheets **44** and **45** may be, e.g., approximately 100 μm , and more preferably approximately 60 μm . The apex angle of the prism projections **44b** and **45b** may be, e.g., 85° or more and 95° or less.

The lower limit of the refractive index of the prism projections **44b** and **45b** may be, e.g., 1.5, and more preferably 1.55. The upper limit of the refractive index of the prism projections **44b** and **45b** may be, e.g., 1.7.

[0052] The prism sheets **44** and **45** may include the base material layers **44a** and **45a** and the prism projections **44b** and **45b**, where the prism projections **44b** and **45b** to which the shape transfer is applied by using an UV curable acryl-based resin are provided on the base material layers **44a** and **45a** made of, e.g., a PET (polyethylene terephthalate) film, or where the prism projections **44b** and **45b** are integrated with the base material layers **44a** and **45a**, respectively. In this embodiment, the prism sheets **44** and **45** are used as the luminance enhancing sheet **48**, but may be replaced with other optical sheets capable of increasing the luminance of the light emitted from the light source **42**.

[Upper Light Diffusion Sheet]

[0053] The upper light diffusion sheet **47** is arranged above the upper prism sheet **45** (or between the display screen **50a** and the upper prism sheet **45**). The upper light diffusion sheet **47** may have a double layer structure consisting of a base material layer and a light diffusion layer. Since the light rays need to pass through the base material layer, the base material layer may be formed mainly of a transparent (e.g., colorless and transparent) synthetic resin. The light diffusion layer may include a resin matrix and resin beads dispersed in the resin matrix.

[Other Optical Sheets]

[0054] Although not shown, a polarizing sheet may be provided above the upper light diffusion sheet **47** (or between the display screen **50a** and the upper light diffusion sheet **47**). The polarizing sheet improves the luminance of the display screen **50a** by preventing light emitted from the backlight unit **40** from being absorbed by the first polarizing plate **6** of the liquid crystal display device **50**.

[Light Diffusion Sheet]

[0055] In FIG. 2, the backlight unit **40** is provided with, e.g., three light diffusion sheets **43** having the same structure and layered with each other. The light diffusion sheet **43** may include one light diffusion sheet, two light diffusion sheets layered with each other, or four or more light diffusion sheets layered with each other. The light diffusion sheet **43** includes a base material layer **21** as shown in FIG. 4. The light diffusion sheet **43** (base material layer **21**) includes a first surface **21a** as a light emitting surface and a second surface **21b** as a light incident surface. That is, the light diffusion sheet **43** is arranged so that the second surface **21b** faces the light sources **42**. A resin for a matrix of the base material layer **21** is not particularly limited as long as being formed of a material that transmits light, and may be, e.g., acrylic, polystyrene, polycarbonate, methyl methacrylate/styrene copolymer (MS) resin, polyethylene terephthalate, polyethylene naphthalate, cellulose acetate, polyimide, or the like. The base material layer **21** may contain a diffusing agent or other additives, or may be substantially free of additives. The additives that the base material layer **21** can contain are not particularly limited, and may be inorganic particles such as silica, titanium oxide, aluminum hydroxide, barium sulfate, and the like, and may be organic particles such as acrylic, acrylonitrile, silicone, polystyrene, polyamide, and the like.

[0056] The thickness of the light diffusion sheet **43** is not limited, but may be, e.g., 3 mm or less (preferably 2 mm or less, more preferably 1.5 mm or less, and further more preferably 1 mm or less) and 50 μm or more. The light diffusion sheet **43** having a thickness of greater than 3 mm makes it difficult to reduce the thickness of the liquid crystal display. The light diffusion sheet **43** having a thickness of less than 50 μm makes it difficult to achieve the luminance uniformity. The light diffusion sheet **43** may have a film shape or a plate shape.

[0057] On the first surface **21a** (the light emitting surface) of the light diffusion sheet **43**, a plurality of recesses **22** having a substantially inverted quadrangular pyramid shape (inverted pyramid shape) are arranged in a two-dimensional matrix as shown in FIG. 5. In other words, the plurality of recesses **22** are arranged along two directions (the X1 direction and the Y1 direction shown in

FIG. 6) perpendicular to each other. The recesses **22** adjacent to each other are parted by a ridge **111**. The ridge **111** extends along the two directions in which the recesses **22** are arranged. A center **112** (apex of the inverted pyramid) of the recess **22** is a deepest portion of the recess **22**. FIG. 5 illustrates that the recesses **22** are arranged in a 5×5 matrix for simplicity, but the actual number of the recesses **22** is much larger. In a two-dimensional arrangement of the plurality of recesses **22**, the recesses **22** may be arranged on the first surface **21a** without a space therebetween, or may be arranged with a predetermined space therebetween. Some of the recesses **22** may be randomly arranged to the extent that the light diffusing effect is not lost.

[0058] The recess **22** may have an apex angle θ of, e.g., 90°. The recesses **22** may have an arrangement pitch p of, e.g., 100 μm . The recess **22** may have a depth of, e.g., 50 μm . The apex angle θ of the recess **22** is an angle formed by cross-sectional lines of a pair of inclined surfaces of the recess **22** which sandwich the center of the recess **22** and face each other, where the cross-sectional lines appear in a cross section when the recess **22** is cut by a plane (longitudinal cross-section) vertical to a plane on which the light diffusion sheet **43** is placed, such that the plane (longitudinal cross-section) passes through the center of the recess **22** (apex **112** of the inverted pyramid) and vertically traverses the pair of inclined surfaces of the recess **22**. The arrangement pitch p of the recesses **22** means a distance between the centers of the recesses **22** (apexes of the inverted pyramids **112**) adjacent to each other (i.e., distance in a direction parallel to the plane on which the light diffusion sheet **43** is placed).

[0059] The second surface **21b** of the light diffusion sheet **43** may be, e.g., a flat surface (mirror surface) or an embossed surface.

[0060] The light diffusion sheet **43** may have a single layer structure consisting of the base material layer **21** with the first surface **21a** having an uneven shape (recesses **22**). The light diffusion sheet **43** may have a double layer structure consisting of a base material layer having two flat surfaces and a layer having one uneven surface. The light diffusion sheet **43** may have a triple or more layer structure including a layer having one uneven surface. The method for manufacturing the light diffusion sheet **43** is not particularly limited. For example, extrusion molding, injection molding, or the like may be employed.

[0061] A single layer light diffusion sheet having an uneven surface may be manufactured by extrusion molding as follows. First, plastic particles in the form of pellets (to which a diffusing agent may be added) are introduced into a single-screw extruder, and molten and kneaded by heating. After that, a molten resin extruded from a T-die is sandwiched and cooled between two metal rolls, then transported by guide rolls, and cut off into sheet plates by a sheet cutter machine to produce light diffusion sheets. Here, the molten resin is sandwiched using the metal roll having a surface with an inverted shape of desired unevenness, whereby the inverted shape of the roll surface will be transferred onto the resin. This allows for shaping of diffusion sheets having surfaces with the desired unevenness. The surface shapes of the rolls are not perfectly transferred onto the resin, and thus may be designed in consideration of how completely the shapes are transferred.

[0062] If a two-layered light diffusion sheet with uneven surfaces is manufactured by extrusion molding, for example, plastic particles as pellets necessary for forming each layer may be introduced into each of two single-screw extruders. Then, the same procedure may be performed for each layer, and the fabricated sheets may be layered.

[0063] Alternatively, the two-layered light diffusion sheet with an uneven surface may be manufactured as follows. First, plastic particles as pellets necessary for forming each layer are introduced into each of two single-screw extruders, and molten and kneaded by heating. Then, molten resins formed into each layer are introduced into a single T-die so that molten resins are layered in the T-die. Then, the layered molten resins extruded from the T-die are sandwiched and cooled between two metal rolls. After that, the layered molten resins are transported by guide rolls, and cut off into sheet plates using a sheet cutter machine, thus yielding a two-layered light diffusion

sheet with an uneven surface.

[0064] The light diffusion sheet may be manufactured by shape-transfer using ultraviolet (UV) as follows. First, an uncured ultraviolet curable resin is filled in a roll having an inverted shape of an uneven shape to be transferred, and a base material is pressed onto the resin. Next, with the roll filled with UV-curing resin being integrated with the base material, the resin is cured by UV irradiation. Next, the sheet to which the shape of the uneven surface has been transferred by using the resin is released from the roll. Finally, the sheet is irradiated with ultraviolet rays again to completely cure the resin, thereby producing a light diffusion sheet having an uneven surface.

[0065] In the present disclosure, the term “substantially inverted quadrangular pyramid” is used in consideration of difficulty in formation of a recess having a geometrically exact inverted quadrangular pyramid shape by an ordinary shape transfer technique. However, the “substantially inverted quadrangular pyramid” encompasses shapes that can be regarded as a true or approximately inverted quadrangular pyramid. Further, “substantial(ly)” XX means that shapes can be approximated to the XX, and “substantially inverted quadrangular pyramids” means shapes that can be approximated to the inverted quadrangular pyramids. For example, the “substantially inverted quadrangular pyramid” includes an “inverted truncated quadrangular pyramid” which has a flat apex and of which the area of the apex is so small that the advantages of the present invention are not lost. The “substantially inverted quadrangular pyramid” also includes a deformation of “inverted quadrangular pyramid” with unavoidable shape variations due to the processing accuracy of industrial production.

Features of Embodiment

[0066] The light diffusion sheet **43** of this embodiment is incorporated in the backlight unit **40** using the plurality of light sources **42** arranged in a two-dimensional matrix. The light diffusion sheet **43** has surfaces, on at least one of which the plurality of recesses **22** having a substantially inverted quadrangular pyramid shape are arranged in a two-dimensional matrix. The intersecting angle between the arrangement direction of the plurality of recesses **22** (the X1 direction and the Y1 direction in FIG. 6) and the arrangement direction of the plurality of light sources **42** (the X direction and the Y direction in FIG. 3) is 30° or more and 60° or less.

[0067] According to the light diffusion sheet **43** of this embodiment, the intersecting angle between the arrangement direction of the recesses **22** and the arrangement direction of the light sources **42** is set to 30° or more and 60° or less. Thus, the intensity of light emitted from the light diffusion sheet **43** can be increased in the diagonal direction of the light source arrangement where the distance between the light sources is long and the luminance is likely to decrease (the direction inclined by 45° with respect to the arrangement direction of the light source **42**). Therefore, the luminance uniformity can be improved. In this embodiment, the expression “the plurality of light sources **42** are arranged in a two-dimensional matrix” encompasses “light source groups each consisting of several small light sources are arranged in a two-dimensional matrix,” and in this case, the small light sources themselves constituting each light source group may not be arranged in a two-dimensional matrix.

[0068] In the light diffusion sheet **43** of this embodiment, if the intersecting angle between the arrangement direction of the recesses **22** and the arrangement direction of the light sources **42** is 35° or more and 55° or less, and more preferably 40° or more and 50° or less, the luminance uniformity can be further improved.

[0069] In the light diffusion sheet **43** of this embodiment, if the recesses **22** are provided on the light emitting surface, the intensity of light emitted from the light diffusion sheet **43** can be easily increased in the diagonal direction of the light source arrangement.

[0070] The backlight unit **40** of this embodiment is incorporated in the liquid crystal display device **50**, and leads light emitted from the plurality of light sources **42** arranged in a two-dimensional matrix to the display screen **50a**. The backlight unit **40** includes the light diffusion sheet **43** of the above embodiment between the display screen **50a** and the plurality of light sources **42**.

[0071] The backlight unit **40** of this embodiment includes the light diffusion sheet **43** of this embodiment, and thus the luminance uniformity can be improved.

[0072] If, in the backlight unit **40** of this embodiment, the light diffusion sheet **43** includes a plurality of the light diffusion sheets **43**, the plurality of the light diffusion sheets **43** diffuse light repeatedly, and thus the luminance uniformity can be further improved. In this case, in at least one of the plurality of light diffusion sheets **43**, the intersecting angle between the arrangement direction of the recesses **22** and the arrangement direction of the light sources **42** is 30° or more and 60° or less.

[0073] The backlight unit **40** of this embodiment may further include a color conversion sheet **46** provided between the display screen **50a** and the plurality of light sources **42** and configured to convert the wavelength of light emitted from the light sources **42**. Accordingly, even when the light sources **42** are light sources other than white light sources, the backlight unit **40** can be configured.

[0074] The backlight unit **40** of this embodiment may include a luminance enhancing sheet **48** provided between the light diffusion sheet **43** and the display screen **50a** and configured to enhance the luminance of the light emitted from the light sources **42**. Accordingly, the luminance uniformity can be improved whereas the luminance can be increased.

[0075] In the backlight unit **40** of this embodiment, the plurality of light sources **42** may be arranged on the reflection sheet **41** provided on the opposite side of the display screen **50a** when viewed from the light diffusion sheet **43**. This causes multiple reflections between the light diffusion sheet **43** and the reflection sheet **41** thus causing further light diffusion, and thus the luminance uniformity is further improved.

[0076] In the backlight unit **40** of this embodiment, when the distance between the light sources **42** and the light diffusion sheet **43** is 5 mm or less, the backlight unit **40** can be downsized. In anticipation of the future reduction in thicknesses of medium-to-small-sized liquid crystal displays, the distance between the light sources **42** and the light diffusion sheet **43** may be preferably 2.5 mm or less, more preferably 1 mm or less, and ultimately 0 mm.

[0077] The liquid crystal display device **50** of this embodiment includes the backlight unit **40** of the above embodiment and the liquid crystal display panel **5**. Therefore, the backlight unit **40** can improve the luminance uniformity. Information apparatuses (e.g., portable information equipment such as laptop computers, tablet computers, and the like) incorporating the liquid crystal display device **50** can also achieve the similar advantages.

[0078] A method of this embodiment for manufacturing a backlight unit **40** includes arranging a plurality of light sources **42**, and arranging a light diffusion sheet **43** having surfaces, on at least one of which a plurality of recesses **22** having a substantially inverted quadrangular pyramid shape are arranged in a two-dimensional matrix, wherein the plurality of light sources **42** and the light diffusion sheet **43** are arranged so that the intersecting angle between the arrangement direction of the plurality of recesses **22** and the arrangement direction of the plurality of light sources **42** is 30° or more and 60° or less.

[0079] According to the method of this embodiment for manufacturing the backlight unit **40**, the intersecting angle between the arrangement direction of the recesses **22** of the light diffusion sheet **43** and the arrangement direction of the light sources **42** is set to 30° or more and 60° or less. Thus, the intensity of light emitted from the light diffusion sheet **43** can be increased in the diagonal direction of the light source arrangement where the distance between the light sources is long and the luminance is likely to decrease. Therefore, the luminance uniformity can be improved.

Example

[0080] An example will be described below.

[0081] In an example, as shown in FIG. 2, three light diffusion sheets **43** each having the same structure with a thickness of 110 μm were layered in the direction in which recesses **22** were arranged on a light emitting surface (first surface **21a**). Above the light diffusion sheets **43**, a lower prism sheet **44**, an upper prism sheet **45**, and an upper light diffusion sheet **47** were arranged in

sequence, where the lower prism sheet **44** and the upper prism sheet **45** had prism extending directions perpendicular to each other. Below the light diffusion sheets **43**, a color conversion sheet **46**, which was a QD sheet, was arranged.

[0082] The light diffusion sheets **43** had the recesses **22** having an inverted pyramid shape with an apex angle of 90° and arranged two-dimensionally at a pitch of $100\ \mu\text{m}$. The light diffusion sheet **43** had a light incident surface (second surface **21b**) as a flat surface.

[0083] The prism sheets **44** and **45** including base material layers **44a** and **45a** made of a PET film and prism projections **44b** and **45b** were formed, where the prism projections **44b** and **45b** were provided on the base material layers **44a** and **45a** by using an UV-curable acryl-based resin made from acrylate. The lower prism sheet **44** had a total thickness of $90\ \mu\text{m}$, and had the prism projections **44b** having a height of $12\ \mu\text{m}$ and an apex angle of 90° and arranged at a pitch of $24\ \mu\text{m}$. The upper prism sheet **45** had a total thickness of $155\ \mu\text{m}$, and had the prism projections **45b** having a height of $25\ \mu\text{m}$ and an apex angle of 90° and arranged at a pitch of $50\ \mu\text{m}$.

[0084] Note that, as the plurality of light sources **42**, an LED array including blue LEDs having a peak wavelength of $450\ \text{nm}$ (full width at half maximum: $16\ \text{nm}$) and arranged two-dimensionally at a pitch of $2.8\ \text{mm}$ was used.

[0085] As described below, the luminance uniformity was examined with variation in the intersecting angle between the arrangement direction of the recesses **22** in the light diffusion sheet **43** of the example and the arrangement direction of the plurality of light sources **42**.

[0086] As shown in FIG. 7, in an initial state for the luminance measurement, the light diffusion sheet **43** was arranged so that one of the arrangement directions of the recesses **22** coincided with a reference direction (arrangement direction of the light sources **42** (X direction)) (i.e., arrangement angle of) 0° ; the lower prism sheet **44** was rotated counterclockwise so that the angle formed by the extending direction of the prism projections **44b** with respect to the X direction was 130° (i.e., arrangement angle of) 130° ; and the upper prism sheet **45** was rotated counterclockwise so that the angle formed by the extending direction of the prism projections **45b** with respect to the X direction was 40° (i.e., arrangement angle of) 40° .

[0087] In a first measurement, the arrangement direction (arrangement angle) of the three light diffusion sheets **43** was rotated counterclockwise from the initial state by 10° each time and 90° in total in order to examine change in the luminance uniformity. The luminance uniformity was evaluated as follows. First, above the plurality of light sources **42** (LED array), as described above, the color conversion sheet **46**, the three light diffusion sheets **43**, the prism sheets **44** and **45**, and the upper light diffusion sheet **47** were arranged in sequence, and a transparent glass plate was further placed thereabove to reduce floating of the sheets. Then, a two-dimensional color luminance meter UA-200 manufactured by Topcon Technohouse Corporation was used to measure the luminance in the vertically upward direction (i.e., in the direction from the LED array toward the glass plate). Next, for two-dimensional luminance distribution images obtained, variation in the light emitting intensity of individual LEDs was corrected and filtering process was conducted to reduce noises of bright/dark spots attributed to foreign materials and the like. Then, average and standard deviation were calculated for the luminance of all the pixels. Finally, the luminance uniformity was calculated with the “luminance uniformity” defined as “average value of luminance/standard deviation of luminance.”

[0088] FIG. 8 shows the change in luminance uniformity obtained in the first measurement (solid line). In FIG. 8, as the light diffusion sheet **43** rotates, the “arrangement angle” increases from 0° to 90° by 10° each time, and the light diffusion sheet **43** has the equivalent arrangement at arrangement angles of) 0° (180° and) 90° (270°). Thus, the “arrangement angle” other than 0° to 90° can be converted into the “arrangement angle” of 0° to 90° by addition or subtraction of a multiple of 90° . The “arrangement angle” converted in this way is equal to the intersecting angle between the arrangement direction of the recesses **22** of the light diffusion sheet **43** and the arrangement direction of the light sources **42** (hereinafter simply referred to as “intersecting angle” in some

cases).

[0089] As shown in FIG. 8, it can be found that in order to improve the luminance uniformity, the arrangement angle of the light diffusion sheet 43, that is, the intersecting angle between the arrangement direction of the recesses 22 and the arrangement direction of the light sources 42 may be set to 30° or more and 60° or less, preferably 35° or more and 55° or less, and more preferably 40° or more and 50° or less. In order to examine the influence of the arrangement angles of the prism sheets 44 and 45 in the first measurement, the same measurement as the first measurement was performed with the arrangement angle of the lower prism sheet 44 set to 90° and the arrangement angle of the upper prism sheet 45 set to 0°. Then, the same correlation as the correlation of the first measurement was found between the luminance uniformity and the intersecting angle (see the dashed line in FIG. 8).

[0090] Next, in a second measurement, the arrangement directions (arrangement angles) of the three light diffusion sheets 43 were fixed to 45° and 0°, respectively, and the prism sheets 44 and 45 were rotated in order to examine change in the luminance uniformity. The method for evaluating the luminance uniformity was the same as in the first measurement.

[0091] FIG. 9 shows the change in the luminance uniformity obtained in the second measurement. In FIG. 9, the solid line represents the result obtained when the arrangement angle of the light diffusion sheet 43 was set to 45°, and the dashed line represents the result obtained when the arrangement angle of the light diffusion sheet 43 was set to 0°, respectively. The horizontal axis in FIG. 9 represents the arrangement angle of the upper prism sheet 45 (the rotation angle of the extending direction of the prism projections 45b (ridges) with respect to the arrangement direction (X direction) of the light sources 42), whereas the arrangement angle of the lower prism sheet 44 (the rotation angle of the extending direction of the prism projections 44b (ridges) with respect to the arrangement direction (X direction) of the light sources 42) is “the arrangement angle of the upper prism sheet 45”+90°.

[0092] As shown in FIG. 9, the luminance uniformity was higher at all arrangement angles of the prism sheets 44 and 45 when the arrangement angle (i.e., the intersecting angle) of the light diffusion sheet 43 was set to 45° than when the arrangement angle of the diffusion sheet 43 was set to 0°. Specifically, when the intersecting angle was set to 45°, the luminance uniformity is improved by approximately three times the variation range dependent on the arrangement angles of the prism sheets 44 and 45.

[0093] Next, in a third measurement, the arrangement directions (arrangement angles) of the three light diffusion sheets 43 were rotated together with the prism sheets 44 and 45 counterclockwise from the initial state by 10° each time and 180° in total in order to examine change in the luminance uniformity. The method for evaluating the luminance uniformity was the same as in the first measurement.

[0094] FIG. 10 shows the change in the luminance uniformity obtained in the third measurement. As shown in FIG. 10, it has been found as in the result of the first measurement that also when the light diffusion sheet 43 is rotated together with the prism sheets 44 and 45 with respect to the arrangement direction of the light sources 42, the luminance uniformity is improved when the arrangement angle (i.e., the intersecting angle) of the light diffusion sheet 43 is 30° or more and 60° or less, preferably 35° or more and 55° or less, and more preferably 40° or more and 50° or less.

[0095] Next, in a fourth measurement, the arrangement direction (arrangement angle) of each one of the three light diffusion sheets 43 was set to 0° or 45° in order to examine change in the luminance uniformity. The method for evaluating the luminance uniformity was the same as in the first measurement.

[0096] FIG. 11 shows the luminance uniformity obtained in the fourth measurement. In FIG. 11, the terms “upper”, “middle”, and “lower” on the horizontal axis refer to the uppermost sheet, the second sheet, and the lowermost sheet of the three light diffusion sheets 43, respectively. As shown

in FIG. 11, the more of the light diffusion sheets **43** had the arrangement angle (i.e., the intersecting angle) of 45°, the higher the luminance uniformity became. When one or two of the light diffusion sheets **43** had the arrangement angle (i.e., the intersecting angle) of 45°, the luminance uniformity of which the one or two of light diffusion sheets **43** was/were arranged in a higher level became higher.

OTHER EMBODIMENTS

[0097] In the above embodiment (including the example: the same applies hereinafter), the color conversion sheet **46**, the light diffusion sheet **43**, the luminance enhancing sheet **48**, and the upper light diffusion sheet **47** constituted the backlight unit **40**. However, the configuration (the type, the arrangement sequence, and the like) of the sheets constituting the backlight unit **40** is not particularly limited.

[0098] In the above embodiment, the second surface **21b** of the light diffusion sheet **43** is either a flat surface (mirror surface) or an embossed surface. Alternatively, the second surface **21b** of the light diffusion sheet **43** may be provided with recesses having an inverted polygonal pyramid shape and capable of being arranged two-dimensionally, or an array of projections such as prism projections.

[0099] The above describes the embodiments of the present disclosure. However, the present disclosure is not limited only to the aforementioned embodiments, and various modifications are possible within the scope of the disclosure. That is, the above description of the embodiments is solely to serve as an example in nature, and is not intended to limit the present disclosure, applications thereof, or uses thereof.

Claims

1. A light diffusion sheet capable of being incorporated into a backlight unit using a plurality of light sources arranged in a two-dimensional matrix at a pitch of 5 mm or less, the light diffusion sheet comprising: surfaces on at least one of which a plurality of recesses having a substantially inverted quadrangular pyramid shape are arranged in a two-dimensional matrix, wherein an intersecting angle between an arrangement direction of the plurality of recesses and an arrangement direction of the plurality of light sources is 30° or more and 60° or less.
2. The light diffusion sheet of claim 1, wherein the intersecting angle is 35° or more and 55° or less.
3. The light diffusion sheet of claim 1, wherein the plurality of recesses are provided on a light emitting surface.
4. A backlight unit incorporated in a liquid crystal display device and leading light emitted from a plurality of light sources arranged in a two-dimensional matrix to a display screen, comprising: the light diffusion sheet of claim 1 provided between the display screen and the plurality of light sources.
5. The backlight unit of claim 4, wherein the light diffusion sheet includes a plurality of the light diffusion sheets.
6. The backlight unit of claim 4, comprising: a color conversion sheet provided between the display screen and the plurality of light sources and configured to convert a wavelength of light emitted from the plurality of light sources.
7. The backlight unit of claim 4, comprising: a luminance enhancing sheet provided between the light diffusion sheet and the display screen and configured to enhance luminance of light emitted from the plurality of light sources.
8. The backlight unit of claim 4, wherein the plurality of light sources are arranged on a reflection sheet provided opposite to the display screen when viewed from the light diffusion sheet.
9. A liquid crystal display device, comprising: the backlight unit of claim 4; and a liquid crystal display panel.

10. An information apparatus comprising the liquid crystal display device of claim 9.

11. A method for manufacturing a backlight unit incorporated in a liquid crystal display device and leading light emitted from a plurality of light sources arranged in a two-dimensional matrix at a pitch of 5 mm or less to a display screen, comprising: arranging the plurality of light sources; and arranging a light diffusion sheet having surfaces, on at least one of which a plurality of recesses having a substantially inverted quadrangular pyramid shape are arranged in a two-dimensional matrix, wherein the plurality of light sources and the light diffusion sheet are arranged so that an intersecting angle between an arrangement direction of the plurality of recesses and an arrangement direction of the plurality of light sources is 30° or more and 60° or less.
