### TECHNICAL FIELD OF THE INVENTION

[0002] The present invention relates to compounds and methods useful for inhibiting E3 ligase Casitas B-lineage lymphoma b (Cbl-b). The invention also provides pharmaceutically acceptable compositions comprising compounds of the present invention and methods of using said compositions in the treatment of various disorders.

### BACKGROUND OF THE INVENTION

[0003] Ubiquitination is a post-translational modification that regulates the function and fate of proteins involved with physiological processes. The addition of ubiquitin to target proteins occurs via a three-step enzymatic process that involves three enzymes. The first enzyme, E1, catalyzes ubiquitin activation. Activated ubiquitin is then transferred from E1 to the ubiquitin-conjugating enzyme, E2. The third enzyme, or E3 ligase, confers substrate specificity and directly catalyzes the transfer of ubiquitin from the E2 into the protein substrate. The addition of poly-ubiquitin chains to proteins serves as a signal leading to degradation into peptides of the ubiquitin-conjugated protein by the proteasome. Additionally, poly- and mono-ubiquitination can also alter cellular localization, function, and interactions of the protein substrate with proteins required for downstream activity and signaling events.

[0004] Ubiquitination controls multiple biological processes that are often dysregulated in disease, including cell cycle, DNA repair, differentiation, and innate and adaptive immunity. Therefore, the discovery of molecules that modulate components of the ubiquitin proteasome system represents an attractive therapeutic opportunity for a wide range of conditions, including cancer and autoimmune disease.

[0005] The compounds and compositions described herein are generally useful for the inhibition of the E3 ligase Casitas B-lineage lymphoma b (Cbl-b).

[0006] Cbl-b is a RING finger E3 ligase and a member of a highly conserved family of Cbl proteins, which in mammals consists of three Cbl genes: Cbl, Cbl-b, and Cbl-c. Cbl proteins interact with target proteins via their protein-protein interaction domains, allowing regulation of multiple signaling pathways, including tyrosine kinase (TK) signaling in multiple cell types. The structure of Cbl proteins consists of an amino-terminal tyrosine kinase binding domain (TKBD), a linker helix region (LHR) and a really interesting new gene (RING) domain, followed by a carboxy-terminal region containing binding sites for Src homology 2 (SH2) and Src homology 3 (SH3) domains. Cbl TKBD is composed of a four-helix bundle (4H), an EF-hand, and a variant SH2 domain, which binds substrates, such as activated TKs, in a phospho-tyrosine dependent manner.

[0007] Ubiquitination of activated receptor TKs by Cbl-b regulates the assembly of endocytic proteins both at the membrane and at sorting endosomes to promote lysosome targeting, degradation and signal termination. Cbl-b is also important for down regulation of signaling from antigen and cytokine receptors through ubiquitination of receptor chains and associated cytosolic TKs, leading to inactivation and/or proteasomal degradation.

[0008] Cbl-b is expressed in immune cell lineages and acts as a major regulator of immune cell activation and maintenance of peripheral tolerance. Cbl-b negatively regulates adaptive immune system signaling by establishing the threshold for the activation of antigen receptors. In T cells, Cbl-b imposes a requirement for a co-stimulatory signal to mount a productive immune response upon T cell receptor (TCR) engagement. Mice deficient in Cbl-b, and more specifically in the RING Zn-finger ligase domain of Cbl-b, showed tumor rejection that is mediated by CD8<sup>+</sup> T cells.

[0009] Additionally, Cbl-b regulates the activity of multiple cell lineages involved in innate immunity, including NK cells, antigen-presenting dendritic cells (DC) and monocytes. Therefore, due to the complexity and diversity of the protein targets of Cbl-b in a variety of immune cells, it is possible that the functions of Cbl-b are cell-type dependent.

[0010] Novel therapeutic approaches aimed at removing inhibitory signals in immune cells to boost a productive immune system have gained recent attention. Given the central role that Cbl-b plays in regulating multiple signaling mechanisms in both innate and adaptive immunity, inhibition of Cbl-b provides therapeutic opportunities, including cancer immunotherapies.

[0011] Cbl-b inhibitors may strengthen the activity of cancer vaccines. For example, it was reported that the adoptive transfer of Cbl-b<sup>-/-</sup> CD8<sup>+</sup> T cells combined with DC vaccines delays tumor growth. Additionally, Cbl-b<sup>-/-</sup> T cells are resistant to inhibition by PDL-1/PD-1 in vitro and in vivo, which supports the rationale combination of Cbl-b inhibitors with anti-PD-1/PD-L1 checkpoint blockade.

[0012] Enhanced expression of Cbl-b associates with better prognosis in lung adenocarcinoma. Moreover, mutations in the RING finger domain of Cbl proteins and Cbl-b linker sequence are found in a variety of disorders and cancers, including Juvenile myelomonocytic leukemia (JMML), preleukemic chronic myelomonocytic leukemia (CMML), Myeloproliferative Neoplasms (MPN), and Acute myeloid leukemia (AML). These observations suggest that degradation impairment of activated TKs represents an important cancer mechanism that involves Cbl proteins. In agreement, multiple reports have demonstrated the ubiquitination of the epidermal growth factor receptor (EGFR) and the platelet derived growth factor receptor alpha (PDGFRα) by Cbl-b. The ubiquitination of these receptors promotes their proteasomal-dependent degradation in a variety of cancer lineages. The degradation of EGFR by Cbl-b leads to lung and gastric cancer cell proliferation and mediates epithelial to mesenchymal transition (EMT) in metastatic breast and gastric cancers. Additionally, amplifications and mutations of both EGFR and PDGFR are major drivers of oncogenic transformation and are commonly found in multiple types of cancer. Thus, Cbl-b inhibition represents an opportunity for both tumor intrinsic and tumor extrinsic therapies.

[0042] As used herein, the term “pharmaceutically acceptable salt” refers to those salts which are, within the scope of sound medical judgment, suitable for use in contact with the tissues of humans and lower animals without undue toxicity, irritation, allergic response and the like, and are commensurate with a reasonable benefit/risk ratio. Pharmaceutically acceptable salts are well known in the art. For example, S. M. Berge et al., describe pharmaceutically acceptable salts in detail in J. Pharmaceutical Sciences, 1977, 66, 1-19, incorporated herein by reference.

Pharmaceutically acceptable salts of the compounds of this invention include those derived from suitable inorganic and organic acids and bases. Examples of pharmaceutically acceptable, nontoxic acid addition salts are salts of an amino group formed with inorganic acids such as hydrochloric acid, hydrobromic acid, phosphoric acid, sulfuric acid and perchloric acid or with organic acids such as acetic acid, oxalic acid, maleic acid, tartaric acid, citric acid, succinic acid or malonic acid or by using other methods used in the art such as ion exchange. Other pharmaceutically acceptable salts include adipate, alginate, ascorbate, aspartate, benzenesulfonate, benzoate, bisulfate, borate, butyrate, camphorate, camphorsulfonate, citrate, cyclopentanepropionate, digluconate, dodecylsulfate, ethanesulfonate, formate, fumarate, glucoheptonate, glycerophosphate, gluconate, hemisulfate, heptanoate, hexanoate, hydroiodide, 2-hydroxy-ethanesulfonate, lactobionate, lactate, laurate, lauryl sulfate, malate, maleate, malonate, methanesulfonate, 2-naphthalenesulfonate, nicotinate, nitrate, oleate, oxalate, palmitate, pamoate, pectinate, persulfate, 3-phenylpropionate, phosphate, pivalate, propionate, stearate, succinate, sulfate, tartrate, thiocyanate, p-toluenesulfonate, undecanoate, valerate salts, and the like.

[0043] Salts derived from appropriate bases include alkali metal, alkaline earth metal, ammonium and N.sup.+(C.sub.1-4alkyl).sub.4 salts. Representative alkali or alkaline earth metal salts include sodium, lithium, potassium, calcium, magnesium, and the like. Further pharmaceutically acceptable salts include, when appropriate, nontoxic ammonium, quaternary ammonium, and amine cations formed using counterions such as halide, hydroxide, carboxylate, sulfate, phosphate, nitrate, loweralkyl sulfonate and aryl sulfonate.

[0044] Unless otherwise stated, structures depicted herein are also meant to include all isomeric (e.g., enantiomeric, diastereomeric, and geometric (or conformational)) forms of the structure; for example, the R and S configurations for each asymmetric center, Z and E double bond isomers, and Z and E conformational isomers. Therefore, single stereochemical isomers as well as enantiomeric, diastereomeric, and geometric (or conformational) mixtures of the present compounds are within the scope of the invention. Unless otherwise stated, all tautomeric forms of the compounds of the invention are within the scope of the invention. Additionally, unless otherwise stated, structures depicted herein are also meant to include compounds that differ only in the presence of one or more isotopically enriched atoms. For example, compounds having the present structures including the replacement of hydrogen by deuterium or tritium, or the replacement of a carbon by a <sup>13</sup>C- or <sup>14</sup>C-enriched carbon are within the scope of this invention. Such compounds are useful, for example, as analytical tools, as probes in biological assays, or as therapeutic agents in accordance with the present invention. In certain embodiments, a warhead moiety, R.sup.1, of a provided compound comprises one or more deuterium atoms. In certain embodiments, Ring B of a provided compound may be substituted with one or more deuterium atoms.

[0045] The structures as drawn represent relative configurations, unless labeled as absolute configurations. The invention contemplates individual enantiomers and racemic mixtures.

[0046] As used herein, a “Cbl-b inhibitor” is a molecule that reduces, inhibits, or otherwise diminishes one or more of the biological activities of Cbl-b (e.g., ubiquitination, regulation of tyrosine kinase signaling, or regulation of immune cell activation and maintenance of peripheral tolerance). Inhibition using the Cbl-b inhibitor does not necessarily indicate a total elimination of the Cbl-b activity. Instead, the activity could decrease by a statistically significant amount including, for example, a decrease of at least about 5%, 10%, 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 95% or 100% of the activity of Cbl-b compared to an appropriate control. In some embodiments, the Cbl-b inhibitor reduces, inhibits, or otherwise diminishes the ubiquitination activity of Cbl-b. In some of these embodiments, the Cbl-b inhibitor reduces, inhibits, or otherwise diminishes the Cbl-b-mediated ubiquitination of tyrosine kinases. The presently disclosed compounds bind directly to Cbl-b and inhibit its ubiquitinating activity.

[0047] By “specific inhibitor” is intended an agent that reduces, inhibits, or otherwise diminishes the activity of a defined target greater than that of an unrelated target. For example, a Cbl-b specific inhibitor reduces at least one biological activity of Cbl-b by an amount that is statistically greater than the inhibitory effect of the antagonist on any other protein (e.g., other E3 ligases). In some embodiments, the IC.sub.50 of the inhibitor for the target is about 90%, 80%, 70%, 60%, 50%, 40%, 30%, 20%, 10%, 5%, 1%, 0.1%, 0.01%, 0.001% or less of the IC.sub.50 of the antagonist for a non-target. The presently disclosed compounds may or may not be a specific Cbl-b inhibitor. A specific Cbl-b inhibitor reduces the biological activity of Cbl-b by an amount that is statistically greater than the inhibitory effect of the antagonist on any other protein (e.g., other E3 ligases). In certain embodiments, the Cbl-b inhibitor specifically inhibits the ubiquitinating activity of Cbl-b. In some of these embodiments, the IC.sub.50 of the Cbl-b inhibitor for Cbl-b is about 90%, 80%, 70%, 60%, 50%, 40%, 30%, 20%, 10%, 0.1%, 0.01%, 0.001%, or less of the IC.sub.50 of the Cbl-b inhibitor for another RING finger E3 ligase or other type of E3 ligase (e.g., Cullin-RING ligase).

[0048] A compound of the present invention may be tethered to a detectable moiety. It will be appreciated that such compounds are useful as imaging agents. One of ordinary skill in the art will

recognize that a detectable moiety may be attached to a provided compound via a suitable substituent. As used herein, the term “suitable substituent” refers to a moiety that is capable of covalent attachment to a detectable moiety. Such moieties are well known to one of ordinary skill in the art and include groups containing, e.g., a carboxylate moiety, an amino moiety, a thiol moiety, or a hydroxyl moiety, to name but a few. It will be appreciated that such moieties may be directly attached to a provided compound or via a tethering group, such as a bivalent saturated or unsaturated hydrocarbon chain. In some embodiments, such moieties may be attached via click chemistry. In some embodiments, such moieties may be attached via a 1,3-cycloaddition of an azide with an alkyne, optionally in the presence of a copper catalyst. Methods of using click chemistry are known in the art and include those described by Rostovtsev et al., *Angew. Chem. Int. Ed.* 2002, 41, 2596-99 and Sun et al., *Bioconjugate Chem.*, 2006, 17, 52-57.

[0049] As used herein, the term “detectable moiety” is used interchangeably with the term “label” and relates to any moiety capable of being detected, e.g., primary labels and secondary labels. Primary labels, such as radioisotopes (e.g., tritium, <sup>32</sup>P, <sup>33</sup>P, <sup>33</sup>S, or <sup>14</sup>C), mass-tags, and fluorescent labels are signal generating reporter groups which can be detected without further modifications. Detectable moieties also include luminescent and phosphorescent groups.

[0050] The term “secondary label” as used herein refers to moieties such as biotin and various protein antigens that require the presence of a second intermediate for production of a detectable signal. For biotin, the secondary intermediate may include streptavidin-enzyme conjugates. For antigen labels, secondary intermediates may include antibody-enzyme conjugates. Some fluorescent groups act as secondary labels because they transfer energy to another group in the process of nonradiative fluorescent resonance energy transfer (FRET), and the second group produces the detected signal.

[0051] The terms “fluorescent label”, “fluorescent dye”, and “fluorophore” as used herein refer to moieties that absorb light energy at a defined excitation wavelength and emit light energy at a different wavelength. Examples of fluorescent labels include, but are not limited to: Alexa Fluor dyes (Alexa Fluor 350, Alexa Fluor 488, Alexa Fluor 532, Alexa Fluor 546, Alexa Fluor 568, Alexa Fluor 594, Alexa Fluor 633, Alexa Fluor 660 and Alexa Fluor 680), AMCA, AMCA-S, BODIPY dyes (BODIPY FL, BODIPY R6G, BODIPY TMR, BODIPY TR, BODIPY 530/550, BODIPY 558/568, BODIPY 564/570, BODIPY 576/589, BODIPY 581/591, BODIPY 630/650, BODIPY 650/665), Carboxyrhodamine 6G, carboxy-X-rhodamine (ROX), Cascade Blue, Cascade Yellow, Coumarin 343, Cyanine dyes (Cy3, Cy5, Cy3.5, Cy5.5), Dansyl, Dapoxyl, Dialkylaminocoumarin, 4',5'-Dichloro-2',7'-dimethoxy-fluorescein, DM-NERF, Eosin, Erythrosin, Fluorescein, FAM, Hydroxycoumarin, IRDyes (IRD40, IRD 700, IRD 800), JOE, Lissamine rhodamine B, Marina Blue, Methoxycoumarin, Naphthofluorescein, Oregon Green 488, Oregon Green 500, Oregon Green 514, Pacific Blue, PyMPO, Pyrene, Rhodamine B, Rhodamine 6G, Rhodamine Green, Rhodamine Red, Rhodol Green, 2',4',5',7'-Tetra-bromosulfone-fluorescein, Tetramethyl-rhodamine (TMR), Carboxytetramethylrhodamine (TAMRA), Texas Red, Texas Red-X.

[0052] The term “mass-tag” as used herein refers to any moiety that is capable of being uniquely detected by virtue of its mass using mass spectrometry (MS) detection techniques. Examples of mass-tags include electrophore release tags such as N-[3-[4'-(p-Methoxytetrafluorobenzyl)oxy]phenyl]-3-methylglyceronyl]isonipecotic Acid, 4'-[2,3,5,6-Tetrafluoro-4-(pentafluorophenoxy)]methyl acetophenone, and their derivatives. The synthesis and utility of these mass-tags is described in U.S. Pat. Nos. 4,650,750, 4,709,016, 5,360,819, 5,516,931, 5,602,273, 5,604,104, 5,610,020, and 5,650,270. Other examples of mass-tags include, but are not limited to, nucleotides, dideoxynucleotides, oligonucleotides of varying length and base composition, oligopeptides, oligosaccharides, and other synthetic polymers of varying length and monomer composition. A large variety of organic molecules, both neutral and charged (biomolecules or synthetic compounds) of an appropriate mass range (100-2000 Daltons) may also

be used as mass-tags.

[0053] The terms “measurable affinity” and “measurably inhibit,” as used herein, means a measurable change in a Cbl-b ubiquitination activity between a sample comprising a compound of the present invention, or composition thereof, and a Cbl-b E3 ligase, and an equivalent sample comprising an Cbl-b E3 ligase, in the absence of said compound, or composition thereof.

#### 5. Uses, Formulation and Administration

##### Pharmaceutically Acceptable Compositions

[0325] According to another embodiment, the invention provides a composition comprising a compound of this invention or a pharmaceutically acceptable derivative thereof and a pharmaceutically acceptable carrier, adjuvant, or vehicle. In certain embodiments, the amount of compound in compositions of this invention is such that is effective to measurably inhibit Cbl-b, or a mutant thereof, in a biological sample or in a patient. In certain embodiments, a composition of this invention is formulated for administration to a patient in need of such composition. In some embodiments, a composition of this invention is formulated for oral administration to a patient.

[0326] The term “patient,” as used herein, means an animal, preferably a mammal, and most preferably a human.

[0327] The term “pharmaceutically acceptable carrier, adjuvant, or vehicle” refers to a non-toxic carrier, adjuvant, or vehicle that does not destroy the pharmacological activity of the compound with which it is formulated. Pharmaceutically acceptable carriers, adjuvants or vehicles that may be used in the compositions of this invention include, but are not limited to, ion exchangers, alumina, aluminum stearate, lecithin, serum proteins, such as human serum albumin, buffer substances such as phosphates, glycine, sorbic acid, potassium sorbate, partial glyceride mixtures of saturated vegetable fatty acids, water, salts or electrolytes, such as protamine sulfate, disodium hydrogen phosphate, potassium hydrogen phosphate, sodium chloride, zinc salts, colloidal silica, magnesium trisilicate, polyvinyl pyrrolidone, cellulose-based substances, polyethylene glycol, sodium carboxymethylcellulose, polyacrylates, waxes, polyethylene-polyoxypropylene-block polymers, polyethylene glycol and wool fat.

[0328] A “pharmaceutically acceptable derivative” means any non-toxic salt, ester, salt of an ester or other derivative of a compound of this invention that, upon administration to a recipient, is capable of providing, either directly or indirectly, a compound of this invention or an inhibitorily active metabolite or residue thereof.

[0329] As used herein, the term “active metabolite or residue thereof” means that a metabolite or residue thereof is also an inhibitor of Cbl-b, or a mutant thereof.

[0330] The subject matter disclosed herein includes prodrugs, metabolites, derivatives, and pharmaceutically acceptable salts of compounds of the invention. Metabolites include compounds produced by a process comprising contacting a compound of the invention with a mammal for a period of time sufficient to yield a metabolic product thereof. If the compound of the invention is a base, the desired pharmaceutically acceptable salt may be prepared by any suitable method available in the art, for example, treatment of the free base with an inorganic acid, such as hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, methanesulfonic acid, phosphoric acid and the like, or with an organic acid, such as acetic acid, maleic acid, succinic acid, mandelic acid, fumaric acid, malonic acid, pyruvic acid, oxalic acid, glycolic acid, salicylic acid, a pyranosidyl acid, such as glucuronic acid or galacturonic acid, an alpha hydroxy acid, such as citric acid or tartaric acid, an amino acid, such as aspartic acid or glutamic acid, an aromatic acid, such as benzoic acid or cinnamic acid, a sulfonic acid, such as p-toluenesulfonic acid or ethanesulfonic acid, or the like. If the compound of the invention is an acid, the desired pharmaceutically acceptable salt may be prepared by any suitable method, for example, treatment of the free acid with an inorganic or organic base, such as an amine (primary, secondary or tertiary), an alkali metal hydroxide or alkaline earth metal hydroxide, or the like. Illustrative examples of suitable salts include, but are not limited to, organic salts derived from amino acids, such as glycine and arginine, ammonia, primary, secondary, and tertiary amines, and cyclic amines, such as piperidine, morpholine and piperazine, and inorganic salts derived from sodium, calcium, potassium, magnesium, manganese, iron, copper, zinc, aluminum and lithium.

[0331] A compound of the invention can be in the form of a “prodrug,” which includes compounds with moieties which can be metabolized in vivo. Generally, the prodrugs are metabolized in vivo by esterases or by other mechanisms to active drugs. Examples of prodrugs and their uses are well known in the art (See, e.g., Berge et al. (1977) “Pharmaceutical Salts”, J. Pharm. Sci. 66:1-19). The prodrugs can be prepared in situ during the final isolation and purification of the compounds, or by separately reacting the purified compound in its free acid form or hydroxyl with a suitable esterifying agent. Hydroxyl groups can be converted into esters via treatment with a carboxylic acid. Examples of prodrug moieties include substituted and unsubstituted, branch or unbranched lower alkyl ester moieties, (e.g., propionic acid esters), lower alkenyl esters, di-lower alkyl-amino lower-alkyl esters (e.g., dimethylaminoethyl ester), acylamino lower alkyl esters (e.g., acetyloxymethyl ester), acyloxy lower alkyl esters (e.g., pivaloyloxymethyl ester), aryl esters

(phenyl ester), aryl-lower alkyl esters (e.g., benzyl ester), substituted (e.g., with methyl, halo, or methoxy substituents) aryl and aryl-lower alkyl esters, amides, lower-alkyl amides, di-lower alkyl amides, and hydroxy amides. Prodrugs which are converted to active forms through other mechanisms in vivo are also included. In aspects, the compounds of the invention are prodrugs of any of the formulae herein.

[0332] Compositions of the present invention may be administered orally, parenterally, by inhalation spray, topically, rectally, nasally, buccally, vaginally or via an implanted reservoir. The term "parenteral" as used herein includes subcutaneous, intravenous, intramuscular, intra-articular, intra-synovial, intrasternal, intrathecal, intrahepatic, intralesional and intracranial injection or infusion techniques. Preferably, the compositions are administered orally, intraperitoneally or intravenously. Sterile injectable forms of the compositions of this invention may be aqueous or oleaginous suspension. These suspensions may be formulated according to techniques known in the art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally acceptable diluent or solvent, for example as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium.

[0333] For this purpose, any bland fixed oil may be employed including synthetic mono- or diglycerides. Fatty acids, such as oleic acid and its glyceride derivatives are useful in the preparation of injectables, as are natural pharmaceutically-acceptable oils, such as olive oil or castor oil, especially in their polyoxyethylated versions. These oil solutions or suspensions may also contain a long-chain alcohol diluent or dispersant, such as carboxymethyl cellulose or similar dispersing agents that are commonly used in the formulation of pharmaceutically acceptable dosage forms including emulsions and suspensions. Other commonly used surfactants, such as Tweens, Spans and other emulsifying agents or bioavailability enhancers which are commonly used in the manufacture of pharmaceutically acceptable solid, liquid, or other dosage forms may also be used for the purposes of formulation.

[0334] Injectable formulations can be sterilized, for example, by filtration through a bacterial-retaining filter, or by incorporating sterilizing agents in the form of sterile solid compositions which can be dissolved or dispersed in sterile water or other sterile injectable medium prior to use.

[0335] In order to prolong the effect of a compound of the present invention, it is often desirable to slow the absorption of the compound from subcutaneous or intramuscular injection. This may be accomplished by the use of a liquid suspension of crystalline or amorphous material with poor water solubility. The rate of absorption of the compound then depends upon its rate of dissolution that, in turn, may depend upon crystal size and crystalline form. Alternatively, delayed absorption of a parenterally administered compound form is accomplished by dissolving or suspending the compound in an oil vehicle. Injectable depot forms are made by forming microcapsule matrices of the compound in biodegradable polymers such as polylactide-polyglycolide. Depending upon the ratio of compound to polymer and the nature of the particular polymer employed, the rate of compound release can be controlled. Examples of other biodegradable polymers include poly(orthoesters) and poly(anhydrides). Depot injectable formulations are also prepared by entrapping the compound in liposomes or microemulsions that are compatible with body tissues.

[0336] Alternatively, pharmaceutically acceptable compositions of this invention may be administered in the form of suppositories for rectal or vaginal administration. These can be prepared by mixing the agent with a suitable non-irritating excipient that is solid at room temperature but liquid at rectal temperature and therefore will melt in the rectum to release the drug. Such materials include cocoa butter, beeswax and polyethylene glycols.

[0337] Pharmaceutically acceptable compositions of this invention may also be administered topically, especially when the target of treatment includes areas or organs readily accessible by

topical application, including diseases of the eye, the skin, or the lower intestinal tract. Suitable topical formulations are readily prepared for each of these areas or organs.

[0338] Topical application for the lower intestinal tract can be effected in a rectal suppository formulation (see above) or in a suitable enema formulation. Topically-transdermal patches may also be used.

[0339] For topical applications, provided pharmaceutically acceptable compositions may be formulated in a suitable ointment containing the active component suspended or dissolved in one or more carriers. Carriers for topical administration of compounds of this invention include, but are not limited to, mineral oil, liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene, polyoxypropylene compound, emulsifying wax and water. Alternatively, provided pharmaceutically acceptable compositions can be formulated in a suitable lotion or cream containing the active components suspended or dissolved in one or more pharmaceutically acceptable carriers. Suitable carriers include, but are not limited to, mineral oil, sorbitan monostearate, polysorbate 60, cetyl esters wax, cetearyl alcohol, 2-octyldodecanol, benzyl alcohol and water.

[0340] Dosage forms for topical or transdermal administration of a compound of this invention include ointments, pastes, creams, lotions, gels, powders, solutions, sprays, inhalants or patches. The active component is admixed under sterile conditions with a pharmaceutically acceptable carrier and any needed preservatives or buffers as may be required. Ophthalmic formulation, ear drops, and eye drops are also contemplated as being within the scope of this invention.

Additionally, the present invention contemplates the use of transdermal patches, which have the added advantage of providing controlled delivery of a compound to the body. Such dosage forms can be made by dissolving or dispensing the compound in the proper medium. Absorption enhancers can also be used to increase the flux of the compound across the skin. The rate can be controlled by either providing a rate controlling membrane or by dispersing the compound in a polymer matrix or gel.

[0341] For ophthalmic use, provided pharmaceutically acceptable compositions may be formulated as micronized suspensions in isotonic, pH adjusted sterile saline, or, preferably, as solutions in isotonic, pH adjusted sterile saline, either with or without a preservative such as benzylalkonium chloride. Alternatively, for ophthalmic uses, the pharmaceutically acceptable compositions may be formulated in an ointment such as petrolatum.

[0342] Pharmaceutically acceptable compositions of this invention may also be administered by nasal aerosol or inhalation. Such compositions are prepared according to techniques well-known in the art of pharmaceutical formulation and may be prepared as solutions in saline, employing benzyl alcohol or other suitable preservatives, absorption promoters to enhance bioavailability, fluorocarbons, and/or other conventional solubilizing or dispersing agents.

[0343] Most preferably, pharmaceutically acceptable compositions of this invention are formulated for oral administration. Such formulations may be administered with or without food. In some embodiments, pharmaceutically acceptable compositions of this invention are administered without food. In other embodiments, pharmaceutically acceptable compositions of this invention are administered with food.

The solid dosage forms of tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells such as enteric coatings and other coatings well known in the pharmaceutical formulating art. They may optionally contain opacifying agents and can also be of a composition that they release the active ingredient(s) only, or preferentially, in a certain part of the intestinal tract, optionally, in a delayed manner. Examples of embedding compositions that can be used include polymeric substances and waxes. Solid compositions of a similar type may also be employed as fillers in soft and hard-filled gelatin capsules using such excipients as lactose or milk sugar as well as high molecular weight polyethylene glycols and the like.

The solid dosage forms of tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells such as enteric coatings, release controlling coatings and other coatings well known in the pharmaceutical formulating art. In such solid dosage forms the active compound may be admixed with at least one inert diluent such as sucrose, lactose or starch. Such dosage forms may also comprise, as is normal practice, additional substances other than inert diluents, e.g., tableting lubricants and other tableting aids such as magnesium stearate and microcrystalline cellulose. Besides inert diluents, the oral compositions can also include adjuvants such as wetting agents, emulsifying and suspending agents, sweetening, flavoring, and perfuming agents.

[0349] The amount of compounds of the present invention that may be combined with the carrier materials to produce a composition in a single dosage form will vary depending upon the host treated, the particular mode of administration. Preferably, provided compositions should be formulated so that a dosage of between 0.01 and 100 mg/kg, 0.01 and 50 mg/kg, or 1 and 25 mg/kg, body weight/day of the compound can be administered to a patient receiving these compositions.

[0350] It should also be understood that a specific dosage and treatment regimen for any particular

patient will depend upon a variety of factors, including the activity of the specific compound employed, the age, body weight, general health, sex, diet, time of administration, rate of excretion, drug combination, and the judgment of the treating physician and the severity of the particular disease being treated. The amount of a compound of the present invention in the composition will also depend upon the particular compound in the composition.

[0351] Compounds of the invention are preferably formulated in dosage unit form for ease of administration and uniformity of dosage. The expression “dosage unit form” as used herein refers to a physically discrete unit of agent appropriate for the patient to be treated. It will be understood, however, that the total daily usage of the compounds and compositions of the present invention will be decided by the attending physician within the scope of sound medical judgment.

#### Uses of Compounds and Pharmaceutically Acceptable Compositions

[0352] The compounds and compositions described herein are generally useful for the inhibition of E3 ligase activity of one or more enzymes. In some embodiments the E3 ligase inhibited by the compounds and methods of the invention is Cbl-b.

[0353] The presently disclosed compounds find use in inhibiting the enzyme Cbl-b. In one embodiment, the subject matter disclosed herein is directed to a method of inhibiting Cbl-b, the method comprising contacting Cbl-b with an effective amount of a compound of the invention or a pharmaceutical composition described herein.

[0354] The presently disclosed compounds can be used in a method for inhibiting Cbl-b. Such methods comprise contacting Cbl-b with an effective amount of a presently disclosed compound. By “contact” is intended bringing the compound within close enough proximity to an isolated Cbl-b enzyme or a cell expressing Cbl-b such that the compound is able to bind to and inhibit the Cbl-b. The compound can be contacted with Cbl-b in vitro or in vivo via administration of the compound to a subject.

[0355] In one aspect, provided herein is a method of inhibiting Cbl-b in a biological sample. The method comprises contacting the sample with a compound disclosed herein (such as a compound of formula I), a pharmaceutically acceptable salt thereof, or a pharmaceutical composition disclosed herein (such as a composition comprising a compound disclosed herein [such as a compound of formula I] and a pharmaceutically acceptable carrier, adjuvant, or vehicle). The term “biological sample”, as used herein, includes, without limitation, cell cultures or extracts thereof; biopsied material obtained from a mammal or extracts thereof; and blood, saliva, urine, feces, semen, tears, or other body fluids or extracts thereof.

[0356] The present disclosure provides methods of inhibiting Cbl-b in a patient. The method comprises administering to a patient a compound disclosed herein (such as a compound of formula I), a pharmaceutically acceptable salt thereof, or a pharmaceutical composition disclosed herein (such as a composition comprising a compound disclosed herein [such as a compound of formula I] and a pharmaceutically acceptable carrier, adjuvant, or vehicle).

[0357] The presently disclosed compounds may or may not be selective Cbl-b inhibitors. A selective Cbl-b inhibitor inhibits the biological activity of Cbl-b by an amount that is statistically greater than the inhibiting effect of the inhibitor on any other protein (e.g., other E3 ligases). In some of these embodiments, the IC<sub>50</sub> of the Cbl-b inhibitor for Cbl-b is about 90%, 80%, 70%, 60%, 50%, 40%, 30%, 20%, 10%, 0.1%, 0.01%, 0.001%, or less of the IC<sub>50</sub> of the Cbl-b inhibitor for another E3 ligase.

[0358] Any method known in the art to measure the ligase activity of Cbl-b may be used to determine if Cbl-b has been inhibited, including in vitro kinase assays, immunoblots with antibodies specific for ubiquitinated targets of Cbl-b, or the measurement of a downstream biological effect of Cbl-b ligase activity.

[0359] The presently disclosed compounds can be used to treat an Cbl-b-dependent disorder. As used herein, a “Cbl-b-dependent disorder” is a pathological condition in which Cbl-b activity is necessary for the genesis or maintenance of the pathological condition.

[0360] Accordingly, in one aspect, provided herein is a method of treating a Cbl-b-mediated disorder, disease, or condition in a patient. The method comprises administering to said patient a compound disclosed herein (such as a compound of formula I), a pharmaceutically acceptable salt thereof, or a pharmaceutical composition disclosed herein (such as a composition comprising a compound disclosed herein [such as a compound of formula I] and a pharmaceutically acceptable carrier, adjuvant, or vehicle).

[0361] Provided herein are compounds and pharmaceutical compositions that inhibit the Cbl-b enzyme, as well as methods of treatment using such compounds and pharmaceutical compositions. The compounds and compositions can be used in methods of modulating the immune system, for treatment of diseases, and for treatment of cells in vivo, in vitro, or ex vivo.

[0362] T-cell activation and T-cell tolerance are tightly controlled processes regulating the immune response to tumors while preventing autoimmunity. Tolerance prevents the immune system from attacking cells expressing “self” antigens. During peripheral tolerance, T-cells that recognize “self” antigens (i.e., self-reactive T-cells) become functionally unresponsive or are deleted after encountering “self” antigens outside of the thymus. Peripheral tolerance processes therefore are important for preventing autoimmune diseases. Normally, cancer cells are removed by activated T-cells that recognize tumor antigens expressed on the surface of the cancer cells. However, in cancer, the tumor microenvironment can support T-cell tolerance to cancer cells, which allows cancer cells to avoid recognition and removal by the immune system. The ability of cancer cells to avoid tumor immunosurveillance can contribute to uncontrolled tumor growth. Therefore, T-cell tolerance can be a form of T-cell dysfunction. General principles of T-cell dysfunction are well known in the art (see Schietinger et al, *Trends Immunol.*, 35: 51-60, 2014). Additional types of T-cell dysfunction that can contribute to uncontrolled tumor growth include T-cell exhaustion, T-cell senescence, and/or T-cell anergy. Therefore, treating T-cell dysfunction, for example, by increasing T-cell activation, increasing T-cell proliferation, decreasing T-cell tolerance, and/or decreasing T-cell exhaustion, is beneficial for preventing or treating cancer. Additional cells of the immune system are important for recognition and removal of cancer cells during immune surveillance. For example, Natural Killer (NK)-cells are lymphocytes of the innate immune system that are able to identify and kill cancer cells (see Martinez-Losato et al, *Clin Cancer Res.*, 21: 5048-5056, 2015). Recent studies have also shown that B-cell subsets with distinct phenotypes and functions exhibit diverse roles in the anti-tumor response (see Saravaria et al, *Cell Mol Immunol.*, 14: 662-674, 2017). Due to their role in tumor surveillance, NK-cells and B-cells may also be amenable as therapeutic targets for the prevention or treatment of cancer.

[0363] Cbl-b is a RING-type E3 ligase that plays an important role in the immune system due to its function as a negative regulator of immune activation. Cbl-b has an essential role in decreasing the activation of T-cells, thereby enhancing T-cell tolerance. Studies have found that Cbl-b-deficient T-cells display lower thresholds for activation by antigen recognition receptors and co-stimulatory molecules (e.g., CD28). For example, loss of Cbl-b in T-cells uncouples the requirement for CD28 costimulation during T-cell activation and proliferation (see Bachmaier et al, *Nature*, 403: 211-216, 2000). Such cbl-b<sup>-/-</sup> T-cells are largely resistant to T-cell anergy, a tolerance mechanism in which T-cells are functionally inactivated and T-cell proliferation is greatly impaired (see Jeon et al, *Immunity*, 21: 167-177, 2004; and Schwartz et al, *Annu Rev Immunol.*, 21: 305-34, 2003). In support of this, loss of Cbl-b in cbl-b knockout mice resulted in impaired induction of T-cell tolerance and exacerbated autoimmunity (see Jeon et al, *Immunity*, 21: 167-177, 2004).

Importantly, loss of Cbl-b in mice also resulted in a robust anti-tumor response that depends primarily on cytotoxic T-cells. One study showed that cbl-b<sup>-/-</sup> CD8<sup>+</sup> T-cells are resistant to T regulatory cell-mediated suppression and exhibit enhanced activation and tumor infiltration. Therapeutic transfer of naive cbl-b<sup>-/-</sup> CD8<sup>+</sup> T-cells was sufficient to mediate rejection of established tumors (see Loeser et al, *J Exp Med.*, 204: 879-891, 2007). Recent studies have shown that Cbl-b also plays a role in NK-cell activation. Genetic deletion of Cbl-b or targeted inactivation

of its E3 ligase activity allowed NK-cells to spontaneously reject metastatic tumors in a mouse model (see Paolino et al, Nature, 507: 508-512, 2014).

[0364] Provided herein are compounds and compositions that are potent inhibitors of Cbl-b and can be used in novel approaches to treat diseases such as cancer. [0517] In some embodiments, an immuno-oncology agent is a T-cell engineered to express a chimeric antigen receptor, or CAR. The T-cells engineered to express such chimeric antigen receptor are referred to as a CAR-T cells.

[0518] CARs have been constructed that consist of binding domains, which may be derived from natural ligands, single chain variable fragments (scFv) derived from monoclonal antibodies specific for cell-surface antigens, fused to endodomains that are the functional end of the T-cell receptor (TCR), such as the CD3-zeta signaling domain from TCRs, which is capable of generating an activation signal in T lymphocytes. Upon antigen binding, such CARs link to endogenous signaling pathways in the effector cell and generate activating signals similar to those initiated by the TCR complex.

[0519] For example, in some embodiments the CAR-T cell is one of those described in U.S. Pat. No. 8,906,682 (June et al.; hereby incorporated by reference in its entirety), which discloses CAR-T cells engineered to comprise an extracellular domain having an antigen binding domain (such as a domain that binds to CD19), fused to an intracellular signaling domain of the T cell antigen receptor complex zeta chain (such as CD3 zeta). When expressed in the T cell, the CAR is able to redirect antigen recognition based on the antigen binding specificity. In the case of CD19, the antigen is expressed on malignant B cells. Over 200 clinical trials are currently in progress employing CAR-T in a wide range of indications. [<https://clinicaltrials.gov/ct2/results?term=chimeric+antigen+receptors&pg=1>].

Exemplary Immune Checkpoint Inhibitors

[0528] In some embodiments, an immuno-oncology agent is an immune checkpoint inhibitor as described herein.

[0529] The term “checkpoint inhibitor” as used herein relates to agents useful in preventing cancer cells from avoiding the immune system of the patient. One of the major mechanisms of anti-tumor immunity subversion is known as “T-cell exhaustion,” which results from chronic exposure to antigens that has led to up-regulation of inhibitory receptors. These inhibitory receptors serve as immune checkpoints in order to prevent uncontrolled immune reactions.

[0530] PD-1 and co-inhibitory receptors such as cytotoxic T-lymphocyte antigen 4 (CTLA-4, B and T Lymphocyte Attenuator (BTLA; CD272), T cell Immunoglobulin and Mucin domain-3 (Tim-3), Lymphocyte Activation Gene-3 (Lag-3; CD223), and others are often referred to as a checkpoint regulators. They act as molecular “gatekeepers” that allow extracellular information to dictate whether cell cycle progression and other intracellular signaling processes should proceed.

[0531] In some embodiments, an immune checkpoint inhibitor is an antibody to PD-1. PD-1 binds to the programmed cell death 1 receptor (PD-1) to prevent the receptor from binding to the inhibitory ligand PDL-1, thus overriding the ability of tumors to suppress the host anti-tumor immune response.

[0532] In some embodiments, the checkpoint inhibitor is a biologic therapeutic or a small molecule. In some embodiments, the checkpoint inhibitor is a monoclonal antibody, a humanized antibody, a fully human antibody, a fusion protein or a combination thereof. In some embodiments, the checkpoint inhibitor inhibits a checkpoint protein selected from CTLA-4, PDL1, PDL2, PDL, B7-H3, B7-H4, BTLA, HVEM, TIM3, GAL9, LAG3, VISTA, KIR, 2B4, CD160, CGEN-15049, CHK 1, CHK2, A2aR, B-7 family ligands or a combination thereof. In some embodiments, the checkpoint inhibitor interacts with a ligand of a checkpoint protein selected from CTLA-4, PDL1, PDL2, PDL, B7-H3, B7-H4, BTLA, HVEM, TIM3, GAL9, LAG3, VISTA, KIR, 2B4, CD160, CGEN-15049, CHK 1, CHK2, A2aR, B-7 family ligands or a combination thereof. In some embodiments, the checkpoint inhibitor is an immunostimulatory agent, a T cell growth factor, an interleukin, an antibody, a vaccine or a combination thereof. In some embodiments, the interleukin is IL-7 or IL-15. In some embodiments, the interleukin is glycosylated IL-7. In an additional aspect, the vaccine is a dendritic cell (DC) vaccine.

[0533] Checkpoint inhibitors include any agent that blocks or inhibits in a statistically significant manner, the inhibitory pathways of the immune system. Such inhibitors can include small molecule inhibitors or can include antibodies, or antigen binding fragments thereof, that bind to and block or inhibit immune checkpoint receptors or antibodies that bind to and block or inhibit immune checkpoint receptor ligands. Accordingly, the present invention provides a single unit dosage form comprising a compound of the current invention, an additional therapeutic agent, and a pharmaceutically acceptable carrier, adjuvant, or vehicle.

[0556] The amount of both an inventive compound and additional therapeutic agent (in those compositions which comprise an additional therapeutic agent as described above) that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration. Preferably, compositions of this invention should be formulated so that a dosage of between 0.01-100 mg/kg body weight/day of an inventive compound can be administered.

[0557] In those compositions which comprise an additional therapeutic agent, that additional therapeutic agent and the compound of this invention may act synergistically. Therefore, the amount of additional therapeutic agent in such compositions will be less than that required in a monotherapy utilizing only that therapeutic agent. In such compositions a dosage of between 0.01-1,000 µg/kg body weight/day of the additional therapeutic agent can be administered.

[0558] The amount of additional therapeutic agent present in the compositions of this invention will be no more than the amount that would normally be administered in a composition comprising that therapeutic agent as the only active agent. Preferably the amount of additional therapeutic agent in the presently disclosed compositions will range from about 50% to 100% of the amount normally present in a composition comprising that agent as the only therapeutically active agent.

[0559] The compounds of this invention, or pharmaceutical compositions thereof, may also be incorporated into compositions for coating an implantable medical device, such as prostheses, artificial valves, vascular grafts, stents and catheters. Vascular stents, for example, have been used to overcome restenosis (re-narrowing of the vessel wall after injury). However, patients using stents or other implantable devices risk clot formation or platelet activation. These unwanted effects may be prevented or mitigated by pre-coating the device with a pharmaceutically acceptable composition comprising a kinase inhibitor. Implantable devices coated with a compound of this invention are another embodiment of the present invention.

Example 445: Cbl-b Biochemical Assay (TR-FRET)

[1528] Recombinant human Cbl-b (aa 36-427) was expressed in *E. coli*, purified and biotinylated in vitro. The protein was diluted to 12 nM in freshly prepared assay buffer consisting of 50 mM HEPES, pH 7.0, 100 mM NaCl, 5 mM MgCl<sub>2</sub>, 0.0100 Triton-X 100, 0.01% BSA and 1 mM DTT.

[1529] Recombinant human Src (aa 254-536)-GSSGSS-Zap-70 (aa 281-297) fusion protein was expressed in *E. coli* and purified. Protein was diluted in assay buffer to 2-5 nM and supplemented

with ATP to 1 mM.

[1530] Fluorescein-BODIPY labeled UBED2D(C85K)-Ub was prepared by conjugating ubiquitin (Ub) labeled at its N-terminus with Fluorescein-BODIPY maleimide (ThermoFisher Catalog no B10250) to *E. coli* expressed and purified UBED2D(C85K) [see Dou et al Nature Structural and Molecular Biology 8: 982-987, 2013]. Recombinant human UBE2D2(C85K) was expressed in *E. coli*, purified and ubiquitinated and Bodipy labelled in vitro. Protein was diluted to 200 nM in assay buffer without MgCl.sub.2 (or Cisbio PPI buffer). Streptavidin-Terbium was added to 2 nM and EDTA to 10 mM, to provide a binding assay mix.

[1531] Compounds were dissolved in DMSO and diluted to prepare a ten-point dilution series. 100 nl of each compound concentration was dispensed in duplicate in a 384 well black assay plate using acoustic dispensing. Wells for maximum signal controls received 100 nl of DMSO only and wells for minimum signal controls received 100 nl of a reference inhibitor compound at a final assay concentration of 100 mM to produce 100% inhibition.

[1532] 5 µl of diluted Cbl-b enzyme was added to all wells of the assay plate and incubated at RT for 30-60 min. The enzyme assay was initiated by addition of 5 µl of Src-Zap/ATP mix to all wells, and the plate incubated at RT for 60 min. The enzyme reaction was terminated and the binding reaction was initiated by adding 10 µl of binding assay mix to all wells and incubating the plate at RT for 60 min prior to assay read.

[1533] Final assay conditions consisted of 6 nM Cbl-b, 1-2.5 nM Src-Zap70, 0.5 mM ATP, 1% (v/v) DMSO (enzyme reaction) and 100 nM UBE2D2(C85K)-Ub-FL-BODIPY, 5 mM EDTA, 1 nM Streptavidin-Tb (binding reaction).

[1534] The HTRF assay signal was measured at 520 nm on an Envision plate reader, with reference signal at 485 or 620 nm. Data was normalized using maximum and minimum assay controls: % Inhibition=100-(100\*((maximum control)-unknown)/(maximum control-minimum control)). A 4-parameter dose-response equation was used to fit the normalized dose-response data and derive an IC50 for test compounds.

[1535] Table 4 shows the activity of selected compounds of this invention in the TR-FRET biochemical assay. Compounds having an activity designated as "A" provided an IC.sub.50≤0.2 µM; compounds having an activity designated as "B" provided an IC.sub.50>0.20 µM. but ≤1 µM; compounds designated as "C" provided an IC.sub.50>1 µM but ≤10 µM; compounds designated as "D" provided an IC.sub.50>10 µM but <50 µM.

The protein was diluted to 12 nM in freshly prepared assay buffer consisting of 50 mM HEPES, pH 7.0, 100 mM NaCl, 5 mM MgCl<sub>2</sub>, 0.01% Triton-X 100, 0.01% BSA and 1 mM DTT. Recombinant human Src (aa 254-536)-GSSGSS-Zap-70 (aa 281-297) fusion protein was expressed in *E coli* and purified. Protein was diluted in assay buffer to 5-20 nM and ATP was added to 1 mM.

[1537] Recombinant human UBE2D2(C85K) was expressed in *E coli*, purified and ubiquitinated and Bodipy labelled in vitro. Protein was diluted to 200 nM in assay buffer without MgCl<sub>2</sub> (or Cisbio PPI buffer). Streptavidin-Terbium was added to 2 nM and EDTA to 10 mM, to provide a binding assay mix.

[1538] Compounds were dissolved in DMSO and diluted to prepare a ten-point half log dilution series. 100 nl of each compound concentration was dispensed in duplicate in a 384 well black assay plate using acoustic dispensing. Wells for maximum signal controls received 100 nl of DMSO only and wells for minimum controls received 100 nl of a reference inhibitor compound at a final assay concentration of 100 mM to produce 100% inhibition.

[1539] 5 µl of diluted c-cbl enzyme was added to all wells of the assay plate and incubated at RT for 30 min. The enzyme assay was initiated by addition of 5 µl of Src-Zap/ATP mix to all wells, and the plate incubated at RT for 60-90 min. The enzyme reaction was terminated and the binding reaction was initiated by adding 10 µl of binding assay mix to all wells and incubating the plate at RT for 60 min prior to assay read.

[1540] Final assay conditions consisted of 6 nM c-cbl, 2.5-10 nM Src-Zap70, 0.5 mM ATP, 1% (v/v) DMSO (enzyme reaction) and 100 nM UBE2D2(C85K)-Ub-FL-BODIPY, 5 mM EDTA, 1

nM Streptavidin-Tb (binding reaction).

[1541] The HTRF assay signal was measured at 520 nm on an Envision plate reader, with reference signal at 485 or 620 nm. Data was normalized using maximum and minimum assay controls: % Inhibition=100-((100\*((maximum control)-unknown)/(maximum control-minimum control))). A 4-parameter dose-response equation was used to fit the normalized dose-response data and derive an IC<sub>50</sub> for test compounds.

Example 447: Jurkat Reporter Assay (NFAT Luciferase)

[1544] A commercial NFAT luciferase construct was purchased, and transfected into Jurkat cells to generate the stable cell line. Jurkat (clone E6-1) cells were engineered for stable expression of an NFAT luciferase reporter. Cells were maintained in RPMI 1640 medium with 10% FBS, 200 μg/ml Hygromycin B and 1% Penicillin/Streptomycin, and assayed in the same medium omitting Hygromycin B.

[1545] Test compounds were dissolved in DMSO (typically at 20 mM) and a ten-point half log dilution series prepared using acoustic dispensing. 125 nl of each compound concentration was

dispensed in duplicate into wells of a 384 well white assay plate, typically providing a top final assay compound concentration of 100 mM. Assay low control wells received DMSO only and high controls received a standard compound (NDI-996179) providing a final assay concentration of 100 mM.

[1546] Jurkat cells were harvested and resuspended in assay medium at  $4.445 \times 10^5$  cells/ml. 22.5  $\mu$ l (10,000 cells) was added to the wells of a white 384 well assay plate and incubated for 15 min at 37° C. in 5% CO<sub>2</sub>. Anti-CD3 antibody (Thermofisher #16-0037-85) was diluted in assay medium to 10  $\mu$ g/ml. 2.5  $\mu$ l was added to wells of the assay plate and incubated for 6 hr at 37° C. in 5% CO<sub>2</sub>. Additional control wells were included which received assay medium in place of anti-CD3.

[1547] Assay plates were equilibrated to RT and 25  $\mu$ l of Steady-Glo® reagent (Promega #E2520) added to all wells. The plate was centrifuged at 100 $\times$ g for 1 min and incubated for 10 min. Luminescence was read on an Envision plate reader.

[1548] Data was normalised using high and low assay controls: % activation =  $100 - (100 * ((\text{high control} - \text{unknown}) / (\text{high control} - \text{low control})))$  Normalised data was fitted to a non-linear regression equation (log inhibitor vs response-variable slope 4-parameters) to derive compound EC<sub>50</sub> values. Fold activation over baseline was expressed as mean luminescence values from high control wells/mean luminescence values from low control wells (anti CD3 only). Maximum activation of compounds was also expressed as a normalised value referenced to the standard compound (maximum % activation of test compound/100)

[1549] Table 6 shows selected compounds of this invention tested in the Jurkat reporter assay. All compounds tested have an EC<sub>50</sub>  $\leq 1$   $\mu$ M.

#### Example 448: T-Cell AlphaLISA Assay

[1551] Test compounds were dissolved in DMSO (typically at 20 mM) and a ten-point half log dilution series prepared using acoustic dispensing. 300 nl of each compound concentration was dispensed in duplicate into wells of a 384 well white assay plate, typically providing a top final assay compound concentration of 50 mM. Assay low control wells received DMSO only and high controls received a standard compound (NDI-996238) providing a final assay concentration of 50 mM.

[1552] Cryopreserved human T-cells were thawed and incubated for 24 hrs prior to use in RPMI 1640 medium containing HI FBS 10% and 1% Penicillin-Streptomycin. Cells were harvested and resuspended in assay medium at a concentration of  $1.25 \times 10^6$  cells per ml. 40  $\mu$ l (50,000 cells) were added to the wells of a white 384 well assay plate and 5  $\mu$ l (0.5  $\mu$ g/ml) anti-CD28 antibody (Life Technologies #16-0289-85) and 5  $\mu$ l (0.75  $\mu$ g/ml) anti-CD-3 antibody (Thermofisher #16-0037-85) is added to the appropriate wells. The plates were then incubated for 48 hours at 37° C. in 5% CO<sub>2</sub>.

[1553] At the end of the incubation period, the assay plate was centrifuges at 300×g for 5 mins and 50  $\mu$ L of the supernatant was transferred to a plate for IL-2 analysis. IL2 levels were measured following the manufacturers protocol (Perkin Elmer #AL221C). Briefly, human IL2 (0.3  $\mu$ g) was dissolved in 100  $\mu$ L 1× AlphaLISA Immunoassay buffer. A half log IL2 standard curve was generated with a top concentration of 30  $\mu$ g/mL in varying amounts of assay medium, as per manufacturers protocol. 2  $\mu$ L of sample or IL-2 standard is added to 384-well Proxiplate alongside 8  $\mu$ L of a 2.5× MIX of AlphaLISA Anti-Analyte Acceptor beads (10  $\mu$ g/mL final) and Biotinylated Antibody Anti-Analyte (1 nM final). The plate is incubated for 60 minutes at 25° C. in the dark prior to the addition of 10  $\mu$ L of 2×SA-Donor beads (40  $\mu$ g/mL final) and further incubated for 30 minutes at 25° C. in the dark. Absorbance was read at 570 nm using Envision (PerkinElmer)

[1554] Data was normalised using high and low assay controls: % activation =  $100 - (100 * ((\text{high control} - \text{unknown}) / (\text{high control} - \text{low control})))$ . Normalised data was fitted to a non-linear regression equation (log inhibitor vs response-variable slope 4-parameters) to derive compound EC<sub>50</sub> values. Fold activation over baseline was expressed as mean luminescence values from high control wells/mean luminescence values from low control wells (anti CD3/anti-CD28 alone). Maximum activation of compounds was also expressed as a normalised value referenced to the standard compound (maximum % activation of test compound/100).

[1555] Table 7 shows the selected compounds of this invention tested in the T-cell assay. All compounds tested have an EC<sub>50</sub> ≤ 1  $\mu$ M.

Example 450: Jurkat pZAP70 HTRF Assay

[1559] Jurkat wild-type (clone E6-1) cells were maintained and assayed in RPMI 1640 medium with 10% FBS, 1% L-glutamine and 1% Penicillin/Streptomycin. Test compounds were dissolved in DMSO (typically at 20 mM) and a ten-point half log dilution series prepared using acoustic dispensing. 62.5 nl of each compound concentration was dispensed in duplicate into wells of a 384 well white assay plate, typically providing a top final assay compound concentration of 10 mM. Assay low control wells received DMSO only and high controls received a standard compound (NDI-205422/NDI-206096) providing a final assay concentration of 10 mM. Jurkat cells were harvested and resuspended in assay medium at  $1 \times 10^7$  cells/ml.  $10^6$  (100,000 cells) was added to the wells of a white 384 well assay plate containing acoustically dispensed compounds and incubated for 15 min at 37° C. in 5% CO<sub>2</sub>. Anti-CD3 antibody (Thermofisher #16-0037-85) was diluted in assay medium to 30 µg/ml and 2 µl was added to wells of the assay plate for a final concentration of 5 µg/ml. The assay plate was incubated for 3 hr at 37° C. in 5% CO<sub>2</sub>. Phospho-Zap70 (Y-319) was quantified using the Cisbio HTRF system (cat #64ZAPPEH). Cells were lysed by addition of 4 µl of lysis buffer for 30 min at RT. 4 µl of diluted donor and acceptor antibody mix was added and the plate sealed and incubated overnight at RT. The assay was read on an Envision plate reader using HTRF read mode with laser excitation and emission read at 665 nm. Data was normalised using high and low assay controls:

$$[00001] \% \text{activation} = 100 - (100 * ((\text{highcontrol}) - \text{unknown}) / (\text{highcontrol} - \text{lowcontrol}))$$

Normalised data was fitted to a non-linear regression equation (log inhibitor vs response-variable slope 4-parameters) to derive compound EC<sub>50</sub> values. Maximum activation of compounds was also expressed as a normalised value referenced to the standard compound (maximum 00 activation of test compound/100).
