STRAP CONNECTOR AND ASSEMBLY THEREOF WITH ENHANCED MATING RETENTION FORCE

Abstract

A strap connector includes an insulating body, a number of conductive terminals, a movable component having a first locking protrusion, a second locking protrusion, and a pull strap. The pull strap is connected with the movable component. The first locking protrusion and the second locking protrusion are adapted to lock with a first locking hole and a second locking hole of a mating connector, respectively, thereby improving the mating retention force when mating with the mating connector. A strap connector assembly having the strap connector is also disclosed.

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS [0001] This application is a continuation of U.S. patent application Ser. No. 17/834,523, filed on Jun. 7, 2022, which claims priority of a Chinese Patent Application No. 202110665729.0, filed on Jun. 16, 2021 and titled “STRAP CONNECTOR AND ASSEMBLY THEREOF”, the entire content of which is incorporated herein by reference.

TECHNICAL FIELD

[0002] The present disclosure relates to a strap connector and an assembly thereof, which belongs to a technical field of connectors.

BACKGROUND

[0003] An existing strap connector assembly usually includes a strap connector and a mating connector. The strap connector includes an insulating body, a plurality of conductive terminals, a locking piece located on one side of the insulating body, and a pull strap connected with the locking piece. The locking piece is provided with a locking protrusion on one side of the insulating body. The mating connector is provided with a locking slot matched with the locking protrusion.

[0004] However, the single-sided locking features in the prior art have a weak holding force when the strap connector and the mating connector are mated with each other, and are likely to affect data transmission due to looseness.

SUMMARY

[0005] In order to achieve the above object, the present disclosure adopts the following technical solution: a strap connector, including: an insulating body, the insulating body including a first side surface, a second side surface, and a mating interface between the first side surface and the second side surface, the mating interface being configured to mate with a mating connector; a plurality of conductive terminals, each conductive terminal including a mating portion positioned to the mating interface; a movable component, the movable component including at least one first locking protrusion disposed on a same side with the first side surface, the at least one first locking protrusion protruding beyond the first side surface; at least one second locking protrusion disposed on a same side with the second side surface, the at least one second locking protrusion protruding beyond the second side surface; and a pull strap, the pull strap being connected with the movable component; wherein the at least one first locking protrusion and the at least one second locking protrusion are lockable with at least one first locking hole and at least one second locking hole of the mating connector, respectively.

[0006] In order to achieve the above object, the present disclosure adopts the following technical solution: a strap connector assembly, including: a strap connector, the strap connector including: an insulating body, the insulating body including a first side surface, a second side surface, and a mating interface between the first side surface and the second side surface; a plurality of conductive terminals, each conductive terminal including a mating portion positioned to the mating interface; a movable component, the movable component including at least one first locking protrusion disposed on a same side with the first side surface, the at least one first locking protrusion protruding beyond the first side surface; at least one second locking protrusion disposed on a same side with the second side surface, the at least one second locking protrusion protruding

beyond the second side surface; and a pull strap, the pull strap being connected with the movable component; and a mating connector, the mating connector being configured to mate with the mating interface of the strap connector; the mating connector including: a mating insulating body; a plurality of mating terminals positioned to the mating insulating body, the plurality of mating terminals being configured to mate with the plurality of conductive terminals for electrical connection; and a metal shell enclosing the mating insulating body, the metal shell including a first side wall and a second side wall disposed opposite to the first side wall; the first side wall defining at least one first locking hole; the second side wall defining at least one second locking hole; wherein the at least one first locking protrusion and the at least one second locking protrusion are lockable with the at least one first locking hole and the at least one second locking hole of the mating connector, respectively.

[0007] In order to achieve the above object, the present disclosure adopts the following technical solution: a strap connector assembly, including: a strap connector, the strap connector including: an insulating body, the insulating body including a first side surface and a second side surface disposed opposite to the first side surface; a plurality of conductive terminals, the plurality of conductive terminals being secured to the insulating body; a movable component, the movable component including two first locking protrusions disposed on a same side with the first side surface, the two first locking protrusions protruding beyond the first side surface along a second direction; two second locking protrusions disposed on a same side with the second side surface, the two second locking protrusions protruding beyond the second side surface along a third direction; the second direction extending oppositely with respect to the third direction; and a pull strap, the pull strap being connected with the movable component; and a mating connector, the mating connector being configured to mate with the strap connector along a first direction; the second direction and the third direction being perpendicular to the first direction; the mating connector including: a mating insulating body; a plurality of mating terminals, the plurality of mating terminals being secured to the mating insulating body, the plurality of mating terminals being configured to mate with the plurality of conductive terminals for electrical connection; and a metal shell, the metal shell enclosing the mating insulating body, the metal shell including a first side wall, a second side wall disposed opposite to the first side wall, a first connecting wall connecting one side of the first side wall and one side of the second side wall, and a second connecting wall connecting another side of the first side wall and another side of the second side wall; the first side wall defining two first locking holes; the second side wall defining two second locking holes; wherein the two first locking protrusions and the two second locking protrusions are lockable with the two first locking holes and the two second locking holes of the mating connector, respectively.

Description

BRIEF DESCRIPTION OF DRAWINGS

[0008] FIG. 1 is a perspective schematic view of a strap connector assembly in accordance with an embodiment of the present disclosure, in which a strap connector is mating with a mating connector, and the mating connector is mounted to a circuit board;

[0009] FIG. 2 is a perspective schematic view of FIG. 1 from another angle;

[0010] FIG. 3 is a rear view of FIG. 1;

[0011] FIG. 4 is a partially exploded perspective view of FIG. 1;

[0012] FIG. 5 is a partially exploded perspective view of FIG. 4 from another angle;

[0013] FIG. 6 is a right side view of the strap connector assembly in FIG. 4 after removing the circuit board;

[0014] FIG. 7 is a further perspective exploded view of the strap connector assembly of the present disclosure;

[0015] FIG. 8 is a further perspective exploded view of the strap connector in FIG. 7;
[0016] FIG. 9 is a further perspective exploded view of the strap connector in FIG. 8;
[0017] FIG. 10 is a top view of the strap connector in FIG. 4;
[0018] FIG. 11 is a schematic cross-sectional view taken along line A-A in FIG. 6; and
[0019] FIG. 12 is a further perspective exploded view of the mating connector in FIG. 7.

DETAILED DESCRIPTION

[0020] Exemplary embodiments will be described in detail here, examples of which are shown in drawings. When referring to the drawings below, unless otherwise indicated, same numerals in different drawings represent the same or similar elements. The examples described in the following exemplary embodiments do not represent all embodiments consistent with this application. Rather, they are merely examples of devices and methods consistent with some aspects of the application as detailed in the appended claims.

[0021] The terminology used in this application is only for the purpose of describing particular embodiments, and is not intended to limit this application. The singular forms “a”, “said”, and “the” used in this application and the appended claims are also intended to include plural forms unless the context clearly indicates other meanings.

[0022] It should be understood that the terms “first”, “second” and similar words used in the specification and claims of this application do not represent any order, quantity or importance, but are only used to distinguish different components. Similarly, “an” or “a” and other similar words do not mean a quantity limit, but mean that there is at least one; “multiple” or “a plurality of” means two or more than two. Unless otherwise noted, “front”, “rear”, “lower” and/or “upper” and similar words are for ease of description only and are not limited to one location or one spatial orientation. Similar words such as “include” or “comprise” mean that elements or objects appear before “include” or “comprise” cover elements or objects listed after “include” or “comprise” and their equivalents, and do not exclude other elements or objects. The term “a plurality of” mentioned in the present disclosure includes two or more.

[0023] Hereinafter, some embodiments of the present disclosure will be described in detail with reference to the accompanying drawings. In the case of no conflict, the following embodiments and features in the embodiments can be combined with each other.

[0024] Referring to FIGS. 1 to 6, the present disclosure discloses a strap connector assembly including a strap connector **100** and a mating connector **200** for mating with the strap connector **100**. In an illustrated embodiment of the present disclosure, the strap connector **100** is a cable connector, and the mating connector **200** is a board-end connector for being mounted to a circuit board **300**. Referring to FIG. 4, the strap connector **100** is adapted to mate with the mating connector **200** along a mating direction B (i.e., a top-to-bottom direction) to realize data transmission.

[0025] Referring to FIGS. 3 to 11, the strap connector **100** includes an insulating body **1**, a plurality of conductive terminals **2** fixed to the insulating body **1**, a movable component **3** installed in the insulating body **1**, an elastic member **4** to abut against the movable component **3**, a cable **5** electrically connected to the conductive terminals **2**, a cover plate **6** fixed to the insulating body **1** and at least partially abutting against the cable **5**, and a pull strap **7** connected to the movable component **3**. The pull strap **7** is configured to drive the movable component **3** to overcome a force of the elastic member **4**, so that the movable component **3** moves along a moving direction C perpendicular to a mating direction B (referring to FIG. 3).

[0026] In the illustrated embodiment of the present disclosure, the insulating body **1** includes a main body portion **11**, a tongue plate **12** protruding downwardly beyond the main body portion **11** along the mating direction B, and a positioning plate **13** further protruding downwardly beyond the tongue plate **12** along the mating direction B. In the illustrated embodiment of the present disclosure, a size of the main body portion **11** in a front-rear direction, a size of the tongue plate **12** in the front-rear direction, and a size of the positioning plate **13** in the front-rear direction become

smaller in sequence, so that the insulating body **1** is of a roughly stepped configuration. In the illustrated embodiment of the present disclosure, referring to FIGS. **4** and **5**, the positioning plate **13** includes a first positioning piece **131** located in the middle, a second positioning piece **132** located on one side of the first positioning piece **131** and spaced apart from the first positioning piece **131**, and a third positioning piece **133** located on the other side of the first positioning piece **131** and spaced apart from the first positioning piece **131**. A size of the first positioning piece **131** in the left-right direction is larger than a size of the second positioning piece **132** in the left-right direction. A size of the first positioning piece **131** in the left-right direction is also larger than a size of the third positioning piece **133** in the left-right direction. In the illustrated embodiment of the present disclosure, a distance between the first positioning piece **131** and the second positioning piece **132** is different from a distance between the first positioning piece **131** and the third positioning piece **133**. This arrangement can play a role in preventing foolishness and prevent the strap connector **100** from being inserted into the mating connector **200** at a wrong angle.

[0027] Referring to FIGS. **6** and **7**, the main body portion **11** includes a first end wall **111** (i.e., a front end wall), a second end wall **112** (i.e., a rear end wall) opposite to the first end wall **111**, a receiving space **110** extending forwardly through the first end wall **111**, a first receiving groove **113** located on one side (i.e., a left side) of the receiving space **110**, and a second receiving groove **114** located on the other side (i.e., a right side) of the receiving space **110**. The receiving space **110** does not extend backwardly through the second end wall **112**. The main body portion **11** includes an inner wall surface **115** exposed to the receiving space **110**. The first receiving groove **113** and the second receiving groove **114** extend through the second end wall **112** along the moving direction C. [0028] Besides, as shown in FIG. **9**, the main body portion **11** also includes a top surface **116**, an opening **1160** extending upwardly through the top surface **116**, a first mounting hole **1161** extending upwardly through the top surface **116** and located on one side of the opening **1160**, and a second mounting hole **1162** extending upwardly through the top surface **116** and located on the other side of the opening **1160**. The main body portion **11** further includes a fixing plate **117** located between the first end wall **111** and the second end wall **112**. In the illustrated embodiment of the present disclosure, the fixing plate **117** is a vertical plate. The fixing plate **117** includes a strap groove **1170** extending through the fixing plate **117** along the moving direction C and a strap shaft **1171** located between an edge (i.e., an upper edge) of the fixing plate **117** and the strap groove **1170**. The pull strap **7** extends through the strap groove **1170** along the moving direction C from a position where it is connected with the movable component **3**. The pull strap **7** is bent around the strap shaft **1171** and then extends beyond the main body portion **11**. The fixing plate **117** further includes a receiving hole **1172**. In the illustrated embodiment of the present disclosure, two receiving holes **1172** are provided. The receiving holes **1172** are recessed on a surface of the fixing plate **117** facing the movable component **3**. That is, the receiving holes **1172** are exposed on the surface of the fixing plate **117** facing the movable component **3**. One end of the elastic member **4** is disposed in the corresponding receiving hole **1172**, and the other end of the elastic member **4** abuts against the movable component **3**.

[0029] Referring to FIGS. **4** to **6**, the tongue plate **12** includes a first surface **121** and a second surface **122** opposite to each other.

[0030] Each conductive terminal **2** includes a mating portion **21** exposed from the tongue plate **12** and a connection portion **22** electrically connected to the cable **5** (referring to FIG. **9**). In the illustrated embodiment of the present disclosure, each mating portion **21** has a flat plate shape. The mating portions **21** of the conductive terminals **2** are exposed from the first surface **121** and the second surface **122**, respectively. In an embodiment of the present disclosure, the conductive terminals **2** are insert-molded with the insulating body **1**. Of course, in other embodiments, the conductive terminals **2** can also be directly assembled to the insulating body **1**. Or, the conductive terminals **2** and an insulating block are combined to form a terminal module before being assembled to the insulating body **1**. The fixing methods of the conductive terminals **2** and the

insulating body **1** are well-known to those skilled in the art, which will not be repeated in the present disclosure.

[0031] In the illustrated embodiment of the present disclosure, the cable **5** extends beyond the main body portion **11** along the moving direction C.

[0032] Referring to FIGS. **7** and **11**, the movable component **3** is at least partially installed in the main body portion **11**. Specifically, the movable component **3** includes a base portion **31** received in the receiving space **110**, a first ejector rod **32** extending from one side of the base portion **31** and received in the first receiving groove **113**, and a second ejector rod **33** extending from the other side of the base portion **31** and received in the second receiving groove **114**.

[0033] The base portion **31** includes a first locking protrusion **311** protruding forwardly beyond the first end wall **111**. In the illustrated embodiment of the present disclosure, two first locking protrusions **311** are provided, which are respectively located on opposite sides (i.e., a left side and a right side) of the base portion **31** so as to improve a mating retention force. In the illustrated embodiment of the present disclosure, the first locking protrusion **311** is integrally formed with the main body portion **11**. Of course, in other embodiments, the first locking protrusion **311** can also be manufactured separately from the main body portion **11**, and then assembled and fixed together. Under this circumstance, the first locking protrusion **311** may be made of a material different from that of the main body portion **11**, for example, a wear-resistant material with better structural strength. The base portion **31** is also provided with a strap connection portion **312**. The pull strap **7** is connected to the strap connection portion **312**. The strap connection portion **312** includes a cutout **310** extending through the base portion along the moving direction C. The strap connection portion **312** is located above the cutout **310**. The strap connection portion **312** is similar to a shaft portion, and is located between the cutout **310** and an edge (i.e., an upper edge) of the base portion **31**. One end of the pull strap **7** passes through the through slot **310** and is sleeved around the pull strap connection portion **312**.

[0034] In the illustrated embodiment of the present disclosure, the elastic member **4** is a compression spring installed between the base portion **31** and the inner wall surface **115** of the main body portion **11**. In the illustrated embodiment of the present disclosure, two compression springs are provided and arranged side by side so as to improve the stability of the movable component **3** when moving. In addition, in order to better position the compression spring, the base portion **31** is further provided with a positioning post **313** (referring to FIG. **11**) at least partially inserted into the compression spring.

[0035] The strap connector **100** includes a second locking protrusion **14** protruding backwardly beyond the second end wall **112**. In the illustrated embodiment of the present disclosure, two second locking protrusions **14** are provided and located on opposite sides (i.e., a left side and a right side) of the second end wall **112** so as to improve the mating retention force. In the illustrated embodiment of the present disclosure, the second locking protrusion **14** and the main body portion **11** are integrally formed to save cost. Of course, in other embodiments, the second locking protrusion **14** can also be made separately from the main body portion **11**, and then assembled and fixed together. Under this circumstance, the second locking protrusion **14** may be made of a material different from that of the main body portion **11**. The first locking protrusion **311** and the second locking protrusion **14** are adapted to lock with locking holes of the mating connector **200** to improve the mating retention force, which will be described in detail later.

[0036] Referring to FIGS. **7**, **8** and **11**, the first ejector rod **32** includes a first groove **320**, a first limiting surface **321** located at one end of the first groove **320** along the moving direction C, and a second limiting surface **322** located at the other end of the first groove **320** along the moving direction C. The first limiting surface **321** is closer to the first end wall **111** than the second limiting surface **322**.

[0037] Similarly, the second ejector rod **33** includes a second groove **330**, a third limiting surface **331** located at one end of the second groove **330** along the moving direction C, and a fourth

limiting surface **332** located at the other end of the second groove **330** along the moving direction C. The third limiting surface **331** is closer to the first end wall **111** than the fourth limiting surface **332**.

[0038] The strap connector **100** includes a first pin **151** and a second pin **152** fixed in the first mounting hole **1161** and the second mounting hole **1162**, respectively. The first pin **151** is inserted into the first groove **320**. The second pin **152** is inserted into the second groove **330**. A size of the first groove **320** along the moving direction C is larger than a size of the first pin **151** along the moving direction C. A size of the second groove **330** along the moving direction C is greater than a size of the second pin **152** along the moving direction C. The first limiting surface **321** is adapted to abut against the first pin **151**, and the third limiting surface **331** is adapted to abut against the second pin **152**, so as to prevent the movable component **3** from moving excessively along the moving direction C under the action of the pull strap **7**. The second limiting surface **322** is adapted to abut against the first pin **151**, and the fourth limiting surface **332** is adapted to abut against the second pin **152**, so as to prevent the movable component **3** from returning excessively along a direction opposite to the moving direction C when the clastic member **4** releases a restoring force.

[0039] The cover plate **6** is received and fixed in the opening **1160** of the main body portion **11**. The pull strap **7** extends beyond the cover plate **6**. In an embodiment of the present disclosure, the cover plate **6** presses against connection portions between the cable **5** and the conductive terminals **2** (i.e., soldering portions of the cable **5** and the conductive terminals **2**) so as to play a protective role.

[0040] Referring to FIGS. **2** to **7** and **12**, the mating connector **200** includes a mating insulating body **81**, a plurality of mating terminals **82** fixed to the mating insulating body **81**, and a metal shell **83** enclosing the mating insulating body **81**. The mating insulating body **81** includes a bottom wall **811** and a plurality of side walls **812** perpendicular to the bottom wall **811**. Referring to FIG. **5**, the bottom wall **811** includes a positioning groove **8110** for receiving the positioning plate **13**. Specifically, the positioning groove **8110** includes a first positioning groove **8111** accommodating the first positioning piece **131**, a second positioning groove **8112** accommodating the second positioning piece **132**, and a third positioning groove **8113** accommodating the third positioning piece **133**. In the illustrated embodiment of the present disclosure, the first positioning groove **8111**, the second positioning groove **8112** and the third positioning groove **8113** extend through the bottom wall **811**.

[0041] Referring to FIGS. **7** and **12**, the side walls **812** are enclosed to form a mating slot **8120** for receiving the tongue plate **12**. The mating terminals **82** are arranged in two rows. Each mating terminal **82** includes an clastic mating arm **821** and a mounting tail **822** for being mounted to the circuit board **300**. The elastic mating arm **821** extends into the mating slot **8120** and is adapted to contact the mating portion **21**.

[0042] The metal shell **83** includes a first side wall **831**, a second side wall **832** disposed opposite to the first side wall **831**, a first connecting wall **833** connecting one side of the first side wall **831** and one side of the second side wall **832**, and a second connecting wall **834** connecting the other side of the first side wall **831** and the other side of the second side wall **832**. The first side wall **831** is provided with a first locking hole **8311** which mates with the first locking protrusion **311**. The second side wall **832** is provided with an clastic arm **8321**. The clastic arm **8321** is provided with a second locking hole **8322** which mates with the second locking protrusion **14**. In the illustrated embodiment of the present disclosure, the clastic arm **8321** is of a cantilevered configuration, which can be elastically deformed under the action of an external force, and return to a position after the external force is released. In the illustrated embodiment of the present disclosure, two elastic arms **8321** are provided and located on left and right sides of the second side wall **832**, respectively. There is a first slot **8323** between the elastic arm **8321** close to the first connecting wall **833** and the first connecting wall **833**. There is a second slot **8324** between the clastic arm **8321** close to the second connecting wall **834** and the second connecting wall **834** (referring to

FIG. 3). By providing the first slot **8323** and the second slot **8324**, the corresponding clastic arm **8321** has better clastic deformation ability.

[0043] When the strap connector **100** is inserted into the mating connector **200**, the positioning plate **13** corresponds to the positioning groove **8110**, the tongue plate **12** corresponds to the mating slot **8120**, and the mating portions **21** of the conductive terminals **2** correspond to the clastic mating arms **821** of the mating terminals **82**. With the insertion of the strap connector **100**, inclined surfaces of the first locking protrusion **311** and the second locking protrusion **14** abut against the first side wall **831** and the second side wall **832**, respectively. The movable component **3** overcomes the force of the clastic member **4** and shrinks inwardly along the moving direction C by a certain distance. When the first locking protrusion **311** and the second locking protrusion **14** move downwardly to correspond to the first locking hole **8311** and the second locking hole **8322**, the clastic member **4** restores elasticity. This causes the movable component **3** return in a direction opposite to the moving direction C. At this time, the first locking protrusion **311** and the second locking protrusion **14** protrude forwardly and backwardly into the first locking hole **8311** and the second locking hole **8322**, respectively to realize the locking of the strap connector **100** and the mating connector **200**. Compared with the prior art, the present disclosure can realize double-sided locking by arranging the first locking protrusion **311** and the second locking protrusion **14** on both sides. Therefore, the mating retention force is improved, and the risk of loosening of the strap connector **100** and the mating connector **200** is reduced.

[0044] When unlocking is required, an external force is applied to pull the pull strap **7**. The pull strap **7** generates a force component along the moving direction C. The component force in this direction overcomes the force of the elastic member **4** and causes the movable component **3** to move along the moving direction C. At this time, on one hand, the first locking protrusion **311** escapes from the first locking hole **8311**; and on the other hand, the first ejector rod **32** and the second ejector rod **33** extend rightward and protrude beyond the second end wall **112** so as to push the corresponding elastic arms **8321** to deform outward, thereby causing the second locking protrusion **14** escape from the second locking hole **8322**. In other words, at this time, the strap connector **100** and the mating connector **200** are unlocked on both sides. The strap connector **100** can be pulled out of the mating connector **200** by applying other forces or by an upward component force applied to the strap **7**.

[0045] The above embodiments are only used to illustrate the present disclosure and not to limit the technical solutions described in the present disclosure. The understanding of this specification should be based on those skilled in the art. Descriptions of directions, although they have been described in detail in the above-mentioned embodiments of the present disclosure, those skilled in the art should understand that modifications or equivalent substitutions can still be made to the application, and all technical solutions and improvements that do not depart from the spirit and scope of the application should be covered by the claims of the application.

Claims

1. A strap connector, comprising: an insulating body, the insulating body comprising a first side surface, a second side surface, and a mating interface between the first side surface and the second side surface, the mating interface being configured to mate with a mating connector; a plurality of conductive terminals, each conductive terminal comprising a mating portion positioned to the mating interface; a movable component, the movable component comprising at least one first locking protrusion disposed on a same side with the first side surface, the at least one first locking protrusion protruding beyond the first side surface; at least one second locking protrusion disposed on a same side with the second side surface, the at least one second locking protrusion protruding beyond the second side surface; and a pull strap, the pull strap being connected with the movable component; wherein the at least one first locking protrusion and the at least one second locking

protrusion are lockable with at least one first locking hole and at least one second locking hole of the mating connector, respectively.

2. The strap connector according to claim 1, wherein the second side surface is disposed opposite to the first side surface; the mating interface is configured to mate with the mating connector along a first direction; the at least one first locking protrusion protrudes beyond the first side surface along a second direction; the at least one second locking protrusion protrudes beyond the second side surface along a third direction, the second direction extends oppositely with respect to the third direction; the second direction and the third direction are perpendicular to the first direction.

3. The strap connector according to claim 1, wherein the number of the at least one first locking protrusion is two, and the number of the at least one second locking protrusion is two; the number of the at least one first locking hole is two, and the number of the at least one second locking hole is two; the two first locking protrusions and the two second locking protrusions are lockable with the two first locking holes and the two second locking holes of the mating connector, respectively.

4. The strap connector according to claim 1, wherein the movable component comprises a strap slot and a strap connection portion disposed adjacent to the strap slot; the pull strap extends through the strap slot and is connected with the strap connection portion.

5. The strap connector according to claim 4, wherein the strap connection portion and the at least one first locking protrusion are integrally formed on the movable component.

6. The strap connector according to claim 1, further comprising at least one cable electrically connected to the plurality of conductive terminals.

7. The strap connector according to claim 1, wherein the mating interface comprises a tongue plate; the mating portion of each conductive terminal is rigid and exposed on the tongue plate.

8. The strap connector according to claim 1, wherein the movable component is at least partially installed in the insulating body, and the movable component is movable along a moving direction.

9. The strap connector according to claim 8, further comprising an elastic member abutting against the movable component.

10. A strap connector assembly, comprising: a strap connector, the strap connector comprising: an insulating body, the insulating body comprising a first side surface, a second side surface, and a mating interface between the first side surface and the second side surface; a plurality of conductive terminals, each conductive terminal comprising a mating portion positioned to the mating interface; a movable component, the movable component comprising at least one first locking protrusion disposed on a same side with the first side surface, the at least one first locking protrusion protruding beyond the first side surface; at least one second locking protrusion disposed on a same side with the second side surface, the at least one second locking protrusion protruding beyond the second side surface; and a pull strap, the pull strap being connected with the movable component; and a mating connector, the mating connector being configured to mate with the mating interface of the strap connector; the mating connector comprising: a mating insulating body; a plurality of mating terminals positioned to the mating insulating body, the plurality of mating terminals being configured to mate with the plurality of conductive terminals for electrical connection; and a metal shell enclosing the mating insulating body, the metal shell comprising a first side wall and a second side wall disposed opposite to the first side wall; the first side wall defining at least one first locking hole; the second side wall defining at least one second locking hole; wherein the at least one first locking protrusion and the at least one second locking protrusion are lockable with the at least one first locking hole and the at least one second locking hole of the mating connector, respectively.

11. The strap connector assembly according to claim 10, wherein the mating connector is configured to mate with the mating interface of the strap connector along a first direction; the at least one first locking protrusion protrudes beyond the first side surface along a second direction; the at least one second locking protrusion protrudes beyond the second side surface along a third direction, the second direction extends oppositely with respect to the third direction; the second

direction and the third direction are perpendicular to the first direction.

12. The strap connector assembly according to claim 10, wherein the number of the at least one first locking protrusion is two, and the number of the at least one second locking protrusion is two; the number of the at least one first locking hole is two, and the number of the at least one second locking hole is two; the two first locking protrusions and the two second locking protrusions are lockable with the two first locking holes and the two second locking holes of the mating connector, respectively.

13. The strap connector assembly according to claim 10, wherein the movable component comprises a strap slot and a strap connection portion disposed adjacent to the strap slot; the pull strap extends through the strap slot and is connected with the strap connection portion.

14. The strap connector assembly according to claim 13, wherein the strap connection portion and the at least one first locking protrusion are integrally formed on the movable component.

15. The strap connector assembly according to claim 10, wherein the strap connector further comprises at least one cable electrically connected to the plurality of conductive terminals.

16. The strap connector assembly according to claim 10, wherein the mating interface comprises a tongue plate; the mating portion of each conductive terminal is rigid and exposed on the tongue plate.

17. The strap connector assembly according to claim 10, wherein the movable component is at least partially installed in the insulating body and the movable component is movable along a moving direction.

18. The strap connector assembly according to claim 17, wherein the strap connector further comprises an elastic member abutting against the movable component.

19. A strap connector assembly, comprising: a strap connector, the strap connector comprising: an insulating body, the insulating body comprising a first side surface and a second side surface disposed opposite to the first side surface; a plurality of conductive terminals, the plurality of conductive terminals being secured to the insulating body; a movable component, the movable component comprising two first locking protrusions disposed on a same side with the first side surface, the two first locking protrusions protruding beyond the first side surface along a second direction; two second locking protrusions disposed on a same side with the second side surface, the two second locking protrusions protruding beyond the second side surface along a third direction; the second direction extending oppositely with respect to the third direction; and a pull strap, the pull strap being connected with the movable component; and a mating connector, the mating connector being configured to mate with the strap connector along a first direction; the second direction and the third direction being perpendicular to the first direction; the mating connector comprising: a mating insulating body; a plurality of mating terminals, the plurality of mating terminals being secured to the mating insulating body, the plurality of mating terminals being configured to mate with the plurality of conductive terminals for electrical connection; and a metal shell, the metal shell enclosing the mating insulating body, the metal shell comprising a first side wall, a second side wall disposed opposite to the first side wall, a first connecting wall connecting one side of the first side wall and one side of the second side wall, and a second connecting wall connecting another side of the first side wall and another side of the second side wall; the first side wall defining two first locking holes; the second side wall defining two second locking holes; wherein the two first locking protrusions and the two second locking protrusions are lockable with the two first locking holes and the two second locking holes of the mating connector, respectively.

20. The strap connector assembly according to claim 19, wherein the strap connector further comprises at least one cable electrically connected to the plurality of conductive terminals.
