Intrusion Prevention Using Reconfiguration Multi-Link Elements in WiFi 7

Abstract

A communication link between an unauthorized AP MLD in a wireless network and a client device is terminated in response to spoofing a communication from the unauthorized AP MLD. The communication is sent from a device different than the unauthorized AP MLD to the client device and includes a source identifier that identifies the unauthorized AP MLD as a source device of the communication. The communication additionally or alternatively may contain or indicate a management or configuration element. The management or configuration element may include a reconfiguration multi-link element that specifies the first wireless communication link as no longer available.

Background/Summary

TECHNICAL FIELD

[0001] The present disclosure relates to a computer-implemented technique for terminating a wireless communication link with an unauthorized device in a wireless network environment.

BACKGROUND

[0002] Within a wireless local area network (WLAN), a connection of a client device to an unauthorized or rogue access point (AP) can pose a significant threat to client security in particular and network security in general. For instance, establishing an illegitimate wireless fidelity (WiFi) hotspot within a wireless communications environment typically can be performed by nearly any user having basic computer skills. A bad actor with minimal computer programming and networking knowledge may set up an unauthorized hotspot, commonly known as a honeypot, within a wireless communications environment by utilizing a device including an off-the-shelf modem or router. Even a commonplace smartphone may hold the capability to function as a cost-free hotspot, e.g., honeypot, accomplishable by configuring specific parameters within the smartphone's general settings menu.

[0003] An unauthorized entity or bad actor may enable a Wifi hotspot, e.g., corresponding to a honeypot, within a WLAN to enable client devices to establish connections with the Internet. Typically, the honeypot may adopt the name of a legitimate establishment's WiFi network or a name that the client would naturally assume to be a permitted or preferred AP. For example, when a client device scans for an available AP (e.g., at a commercial establishment or in the vicinity of an enterprise) and encounters the name, the client may initiate a connection with the honeypot without suspicion. Once the client device connects, e.g., via an authentication process, a malevolent actor or unpermitted entity behind the connection or enabling the connection may be able to scrutinize and intercept the client's private information through sundry stratagems or surreptitious acts such as traffic filtering. As WLAN and wireless intrusion prevention system (WIPS) technologies advance and increase in complexity, challenges related to protecting users and client devices from connecting to unauthorized APs continue to grow and evolve commensurately.

[0004] The approaches described in this section are approaches that could be pursued, but not necessarily approaches that have been previously conceived or pursued. Therefore, unless otherwise indicated, it should not be assumed that any of the content or approaches described in this section qualify as prior art merely by virtue of their inclusion in this section.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

[0005] The embodiments of this disclosure are illustrated by way of example and not by way of limitation in the figures of the accompanying drawings. It should be noted that references to “an” or “one” embodiment of the disclosure in this disclosure are not necessarily to the same embodiment of the disclosure, and they mean at least one. In the drawings:

[0006] FIG. 1A illustrates an example computing system including multiple AP MLDs and a client device in a wireless environment and including a network manager station in accordance with one or more embodiments of the disclosure;

[0007] FIG. 1B depicts the network manager station in accordance with one or more embodiments of the disclosure;

[0008] FIG. 2 shows an example set of operations for terminating a first wireless communication link between the client device and an unpermitted AP MLD in accordance with one or more embodiments of the disclosure;

[0009] FIGS. 3A-3D depict an example implementation of terminating a prohibited wireless communication link between a client device and an unpermitted AP MLD in accordance with one or more embodiments of the disclosure; and

[0010] FIG. 4 illustrates a block diagram that includes a computer system in accordance with one or more embodiments of the disclosure.

DETAILED DESCRIPTION

[0011] In the following description, for the purposes of explanation, numerous specific details are set forth in order to provide a thorough understanding of the disclosure. One or more embodiments of the disclosure may be practiced without these specific details. Features described in one embodiment of the disclosure may be combined with features described in a different embodiment of the disclosure. In some examples, well-known structures and devices are described with reference to a block diagram form in order to avoid unnecessarily obscuring the present invention.

[0012] 1. GENERAL OVERVIEW [0013] 2. MULTI-LINK OPERATION (MLO) INTRUSION PREVENTION ARCHITECTURE [0014] 3. TERMINATING A LINK WITH AN ACCESS POINT MULTI-LINK DEVICE (AP MLD) [0015] 4. EXAMPLE EMBODIMENT [0016] 5. HARDWARE OVERVIEW [0017] 6. MISCELLANEOUS; EXTENSIONS

1. GENERAL OVERVIEW

[0018] One or more embodiments terminate a wireless communication link between a client device and an AP MLD by transmitting a frame, e.g., a management frame, that spoofs the frame-originator as the AP MLD. For instance, following a multi-link setup or association process, one or more communication links, e.g., channels, may be established between the client device and the AP MLD. A computing system may determine that a communication link between the client device and the AP MLD is prohibited. Based on or responsive to determining that the communication link is prohibited, the computing system may cause transmission from a device other than the AP MLD of a frame, e.g., management frame, that spoofs the frame-originator as the AP MLD by identifying the AP MLD as a source, e.g., transmitter, of the frame.

[0019] The management frame, as referred to herein, includes any type of frame with a reconfiguration multi-link element indicating that a communication link is no longer available. The reconfiguration multi-link element may indicate, for instance, that the wireless communication link is no longer available. In addition to identifying the frame-originator as the AP MLD, the frame, e.g., management frame, may identify the client device as a destination for or recipient of the frame. The client device receives and processes the management frame as if the management frame were transmitted by the AP MLD. As a consequence of the client device receiving the management frame and/or of the management frame containing the reconfiguration multi-link element (indicating that the communication link is no longer available), the client device terminates, e.g., initiates termination of, the communication link specified by the management frame.

[0020] One or more embodiments of the disclosure described in this Specification and/or recited in the claims may not be included in this General Overview section.

2. MULTI-LINK OPERATION (MLO) INTRUSION PREVENTION ARCHITECTURE

[0021] In general, according to an aspect or feature of the disclosure, one or more embodiments relate to a method that includes identifying, by one or more processors, an impermissible and/or prohibited wireless communication link between an AP MLD and a client device. In response to identifying the impermissible or prohibited wireless communication link between the AP MLD and the client device, a message or a frame may be accessed, generated, and/or created. The message or frame may include, for example, either or both of a source identifier and a management or configuration element. The management or configuration element may comprise, for example, a reconfiguration multi-link element indicating that the AP MLD is a source device of the frame and that the impermissible or prohibited wireless communication link is no longer available, respectively. The method may further include initiating, by the one or more processors, transmitting of the frame from a device different than the AP MLD. In one or embodiments, the transmitting of

the frame causes the client device to initiate termination of the impermissible or prohibited wireless communication link.

[0022] According to another aspect or feature, one or more embodiments of the disclosure relate to one or more non-transitory media having instructions which, when executed by one or more processors, cause a group of operations. The operations in general may include identifying an AP MLD that is prohibited from connecting (or that is not authorized or permitted to connect) to a client device and determining that the AP MLD is connected to the client device over a first wireless communication link. The operations may further include, for example, responsive to determining that the AP MLD is connected to the client device over the first wireless communication link, spoofing a communication from the AP MLD by transmitting, from a device different than the AP MLD, a message or frame. The message or frame may contain or indicate a source identifier that identifies the AP MLD as a source device of the frame. The message or frame additionally or alternatively may contain or indicate a management or configuration element. The management or configuration element may comprise, for example, a reconfiguration multi-link element that specifies the first wireless communication link as no longer available. The client device may be caused to initiate termination of the first wireless communication link in response to receipt and processing by the client device of the frame.

[0023] Another aspect or feature of the disclosure relates in general to a computing system having one or more processors configured to facilitate determining that a certain AP MLD, prohibited from connecting (or not permitted to connect) to a client device, is connected to the client device over a first wireless communication link, followed by spoofing a communication of a signal or frame. The spoofed communication may include a source identifier indicating the AP MLD as an originator, source device, or sender of the frame. The signal or frame may in certain embodiments additionally include, for example, a reconfiguration message. The reconfiguration message may comprise, for example, a multi-link element indicating that the first wireless communication link is no longer available. In accordance with at least one aspect of the disclosure, the signal or frame is configured to cause the client device to facilitate, initiate, or instruct termination of the first wireless communication link. Once the frame has been received and processed by the client device, the client device according to one or more embodiments of the disclosure initiates and/or causes the termination of the first wireless communication link with the AP MLD.

[0024] Referring more particularly to the drawings, FIG. 1A illustrates an example computing system **100** including a private network **102**, a gateway device **104**, and a network connection to a network representative of at least a portion of the Internet **106**. Any part or all of the private network **102**, the gateway device **104**, and the network representative of the Internet **106**, e.g., the Internet, may take a variety of forms, be represented as multiple components, or be capable of communicating with any number of sources or components referenced herein. According to one or more embodiments of the disclosure, the computing system **100** of FIG. 1A may further include a wireless environment **108** and a network manager station **130**. Any part of the wireless environment **108** or the network manager station **130** may take sundry forms and/or differing numbers of components according to certain embodiments of the disclosure. Any part of the wireless environment **108** or the network manager station **130** may be capable of communicating with various sources or components referenced herein and other sources or components.

[0025] The private network **102** according to embodiments of the disclosure may include, without limitation, one or more LANs, e.g., corresponding to an intranet. Such networking environments may be commonplace in enterprise computer networks and wireless communication environments. In exemplary implementations of the disclosure, such networks may comprise any of a variety of possible private, commercial, and/or enterprise networks.

[0026] The gateway device **104** and the Internet **106** may include connections, structures, and architectures according to known or corresponding systems and arrangements. The gateway device **104** and the Internet **106** may operate according to known protocols and corresponding known

functions. Behind and/or protected by the gateway device **104** exists at least a portion of the private network **102** and/or at least a portion of the wireless environment **108** in certain embodiments. [0027] Within the wireless environment **108** in accordance with embodiments of the disclosure, permitted AP MLDs **112a-112n** and a client device **122** may communicate with each other. The permitted AP MLDs **112a-112n** and the client device **122** may communicate within the wireless environment **108** via multiple radios included in each of the permitted AP MLDs **112a-112n** and the client device **122** and/or via the private network **102**. For instance, the permitted AP MLDs **112a-112n** and the client device **122** may communicate wirelessly within the wireless environment **108**, e.g., amongst one another, via Radio A **114a**-Radio N **114n**, Radio A **116a**-Radio N **116n**, and radio device(s) of the client device **122**, respectively.

[0028] The wireless environment **108** according to certain embodiments of the disclosure includes or is related to each of a spectrum analyzer **110**, multiple permitted AP MLDs such as or including the permitted AP MLDs **112a-112n**, the unpermitted AP MLD **118**, and the client device **122**. One or more of the spectrum analyzer **110**, the permitted AP MLDs **112a-112n**, the unpermitted AP MLD **118**, and the client device **122** may take a variety of configurations and/or components and communicate with various sources/components referenced herein or other sources/components. In typical embodiments, Radio A **114a**-Radio N **114n** may transmit and receive wireless communication signals **124a**, Radio A **116a**-Radio N **116n** may transmit and receive wireless communication signals **124n**, and Radio A **120a**-Radio N **120n** may transmit and receive wireless communication signals **124x** within the wireless environment **108**.

[0029] The spectrum analyzer **110** may be configured to detect and/or analyze electromagnetic signals, e.g., wireless electromagnetic energy and electromagnetic waves, corresponding to transmissions between or among wireless communication devices (e.g., radios of wireless communication devices such as Radio A **114a**-Radio N **114n**, Radio A **116a**-Radio N **116n**, radio device(s) of the client device **122**, Radio A **120a**-Radio N **120n**) within the wireless environment **108**. In one or more embodiments, the spectrum analyzer **110** is configured to detect and analyze spectrum-related information corresponding to communications, e.g., wireless communications, transmitted by wireless communication devices, e.g., any of the above-described radios, within the wireless environment **108**.

[0030] Spectrum information generated by the spectrum analyzer **110** may be transmitted as analysis signals by the spectrum analyzer **110** to one or more other components or devices such as the network manager station **130**. The network manager station **130**, e.g., the connection detector **132** (FIG. 1B) of the network manager station **130**, may in example implementations of the disclosure receive the analysis signals from the spectrum analyzer **110** and use/process the analysis signals to determine network metrics and detect events corresponding to the wireless environment **108**. For instance, the network metrics and events may comprise or indicate a formation, presence, and/or use of a prohibited wireless communication link, e.g., between the unpermitted AP MLD **118** and the client device **122**. Techniques and systems for detecting and analyzing electromagnetic signals, e.g., corresponding to wireless communication links, may be based on technologies or applications known or apparent from a reading of this description, including modifications or extensions thereof. For example, such technologies or applications may pertain to the fields of antennas and wireless communication transmissions.

[0031] The permitted AP MLDs **112a-112n** and the unpermitted AP MLD **118** according to the illustrated embodiment may each include a plurality of radio antennae. As depicted in FIG. 1A, the plurality of radio antennae of permitted AP MLDs **112a-112n** may each include respective electrical instruments, including for example Radio A **114a**-Radio N **114n** and Radio A **116a**-Radio N **116n**, while the plurality of radio antennae of unpermitted AP MLD **118** may include for example Radio A **120a**-Radio N **120n**. In accordance with certain embodiments described herein, a plurality of AP MLDs, e.g., the permitted AP MLD **112a** and the permitted AP MLD **112n**, are configured to support a plurality of multi-link enabled user or client devices in a multi-link enabled wireless

communications environment, e.g., the wireless environment **108**. For instance, at least one AP MLD such as the permitted AP MLD **112a** in the wireless environment **108** may be configured to support multi-link transmissions to and from at least one multi-link enabled client device, e.g., the client device **122** over multiple wireless channels (links) in the wireless environment **108**. [0032] The client device **122** may comprise, according to certain embodiments, a user device such as a mobile wireless communication device configured to operate as a multi-link enabled component within a given WiFi 7 wireless communications environment, e.g., the wireless environment **108**. For example, the client device **122** may comprise a tablet or smartphone configured to operate as a multi-link enabled computing device within a WiFi 7 wireless communications environment, e.g., the wireless environment **108**. The client device **122** may be enabled to access multiple wireless links or channels, e.g., via at least a portion of the plurality of AP MLDs, at or near a same time in certain embodiments. For example, a multi-link operation (MLO) paradigm implemented within the wireless environment **108** may allow the client device **122** to connect to both a first link or channel, e.g., a 5-GHz wireless channel, and a second link or channel, e.g., a 6-GHz wireless channel. The first link or channel and the second link or channel may be offered, for example, by one or more of the plurality of AP MLDs for use, e.g., at the same time, by the client device **122** for wirelessly sending and receiving data.

[0033] In one or more embodiments, the computing system **100** may include or correspond to more or fewer components than the components illustrated in FIG. 1A. Additionally or alternatively, one or more client devices may be enabled via one or more of the plurality of AP MLDs to send and receive, e.g., simultaneously send and receive, data across different frequency bands and channels via the one or more of the plurality of AP MLDs to achieve performance enhancements as compared to non-MLO wireless environment paradigms. The performance enhancements may include, for example, one or more of increased throughput, reduced latency, or improved reliability as compared to non-MLO wireless communication paradigms or architectures. The increased throughput, reduced latency, or improved reliability may facilitate or enhance, for example, emerging computing applications such as virtual reality (VR), augmented reality (AR), online gaming, remote office communications, and cloud computing.

[0034] The one or more client devices enabled via one or more of the plurality of AP MLDs to send and receive data across different frequency bands and channels may in one or more embodiments each be structured similarly to the client device **122**. For instance, the one or more client devices may be configured to send and receive the data on the frequency bands or channels simultaneously, near simultaneously, and/or pursuant to one or more send/receive orders, send/receive time intervals, or send/receive sequences. In certain embodiments of the disclosure, an alternating multi-link MLO paradigm may enable, for example, a client device such as the client device **122** to perform operations, e.g., sending and/or receiving data, via one or more of the plurality of AP MLDs, by alternating between two frequency bands and channels. For example, the operations may be performed by the client device **122** transmitting first and second portions of the data on first and second wireless channels or links, respectively, in an alternating fashion as compared to a simultaneous or tandem fashion.

[0035] The network manager station **130** according to embodiments may include components and contents as described and referenced in regard to FIG. 1B. The network manager station **130** may be arranged, for example, to facilitate operations corresponding to one or more of the operations described and referenced in relation to FIG. 2. In one or more embodiments of the disclosure, the network manager station **130** is configured to facilitate detection within the wireless environment **108** and termination within the wireless environment **108** of a wireless communication link between a user or client device and an unauthorized AP MLD. In accordance with certain implementations, the network manager station **130** is constructed and configured to determine that an unpermitted connection, e.g., wireless communication link within the wireless environment **108**, exists between a client device and a non-authorized AP MLD and to cause termination of the

unpermitted connection. For instance, the network manager station **130** may be configured to cause transmission, e.g., via the network manager station **130** and/or via a device such as the permitted AP MLD **112a**, of a message that includes or references an instruction or indication that the recipient of the message, e.g., the client device **122**, initiate termination of a prohibited wireless communication link between the client device **122** and the unpermitted AP MLD **118**.

[0036] One of skill in the art will appreciate that the spectrum analyzer **110**, the permitted AP MLDs **112a-112n**, the unpermitted AP MLD **118**, and the client device **122**, and/or any portion(s) of the computing system **100** may be implemented as a cloud-based platform or may be distributed across multiple physical locations. The computing system **100** in some implementations may comprise an adaptive multi-agent operating system, an adaptive single agent system, or a non-agent system. The computing system **100** may include or operate with, in relation to, and corresponding to any of a distributed computing system, a distributed or centralized computing system, a virtual computing system, or any combination thereof.

[0037] FIG. **1B** depicts elements and particulars regarding the network manager station **130** in accordance with one or more embodiments of the disclosure. As elucidated in the figure, the network manager station **130** may comprise one or more of a connection detector **132**, a connection evaluator **134**, and a spoofing frame generator **136**. Certain elements and components illustrated in FIG. **1A** and/or FIG. **1B** may be local to or remote from each other. Various elements and components illustrated in FIG. **1A** and/or FIG. **1B** may be implemented in software and/or hardware. Each of one or more of the elements or components may be distributed over multiple applications and/or machines. Multiple elements or components may be combined into one application, element, component, and/or machine. Functions described with respect to one element or component may instead be performed by another element or component.

[0038] The connection detector **132** of the network manager station **130** may be configured to detect, for example, one or more connections, e.g., between one or more AP MLDs and/or one or more client devices corresponding to one or more wireless communication links. In certain embodiments of the disclosure, the connection detector **132** is configured to detect wireless connections and/or wireless communication links between AP MLDs and client devices within or corresponding to the wireless environment **108**. According to some embodiments, the connection detector **132** is communicatively coupled to the spectrum analyzer **110** and is configured to detect a wireless connection, e.g., wireless communication link between the unpermitted AP MLD **118** and the client device **122**, based on signals, e.g., the analysis signals, communicated with, e.g., received from, the spectrum analyzer **110**. Techniques and systems for detecting connections, e.g., communication links between an AP MLD such as the unpermitted AP MLD **118** and a user device or client device such as the client device **122**, may be based on technologies or applications known or apparent from a reading of this description, including modifications or extensions thereof. For example, such technologies or applications may pertain to fields and technologies relating to wireless intrusion prevention systems.

[0039] The connection evaluator **134** may be configured to evaluate, for example, signals and data relating to the spectrum analyzer **110** and/or the connection detector **132**. In one or more embodiments, the connection evaluator **134** is configured to evaluate wireless connections and/or wireless communication links within the wireless environment **108**. Evaluating a wireless connection or wireless communication links may comprise, for example, determining that a particular wireless connection or wireless communication link in the wireless environment **108** is active between two devices that are communicating in the wireless environment **108**. In certain embodiments, evaluating a wireless connection or wireless communication link comprises, for instance, determining that a particular wireless connection or wireless communication link in the wireless environment **108** exists, is active, and/or is able to facilitate wireless communications between a client device **122** and an unpermitted AP MLD. According to example embodiments, the connection evaluator **134** is configured to evaluate one or more connections, e.g., communication

links between one or more AP MLDs and one or more user or client devices. In one or more implementations, the connection evaluator **134** is configured to evaluate signal information (e.g., based on the spectrum information and/or the analysis signals) relating to, indicating, or describing wireless connections, e.g., wireless communication links within the wireless environment **108**. Additionally or alternatively, the signal information, e.g., relating to, indicating, or describing wireless connections or wireless communication links, may correspond to, be evaluated by, be used by, or be generated by one or both of the spectrum analyzer **110** and/or the connection detector **132**. [0040] According to certain implementations, the connection evaluator **134** is communicatively coupled to the spectrum analyzer **110** and/or the connection detector **132**. The connection evaluator **134** is configured to evaluate a wireless connection, e.g., wireless communication link between the unpermitted AP MLD **118** and the client device **122**, based on signals communicated with, e.g., received from, the spectrum analyzer **110** and/or the connection detector **132**. Techniques and systems for evaluating connections, e.g., wireless communication links between an AP MLD and a user/client device, may be implemented by or in connection with the connection evaluator **134** based on technologies or applications relating to the field of wireless intrusion prevention systems. Additionally or alternatively, techniques and systems implemented at the connection evaluator **134** for evaluating connections, e.g., communication links between an AP MLD such as the unpermitted AP MLD **118** and a user device or client device such as the client device **122**, may be based on technologies or applications known or apparent from a reading of this description, including modifications or extensions thereof.

[0041] The spoofing frame generator **136** may in certain embodiments be configured to generate one or more spoofing frames, reconfiguration commands, and/or management instructions. Additionally or alternatively, the spoofing frame generator **136** may be configured to generate portion(s) of one or more spoofing frames and/or configured to generate frame information fashioned to facilitate creation and/or transmission of one or more spoofing frames. In one or more embodiments, the spoofing frame generator **136** is configured to generate one or more spoofing frames and/or portions of one or more spoofing frames based on, e.g., using, the spoofed frames **146** at the data repository **140**. Additionally or alternatively, the spoofing frame generator **136** is configured to generate frame information configured to facilitate creation and/or transmission of one or more spoofing frames based on, e.g., using, the spoofed frames **146** at the data repository **140**.

[0042] In one or more embodiments, the spoofing frame generator **136** is configured to generate one or more frames and/or packets that when transmitted to a client device cause the client device to initiate termination of an unauthorized wireless communication link between the client device and an unpermitted AP MLD. According to an aspect of the disclosure, the wireless communication link between the client device and the unpermitted AP MLD is indicated, e.g., specified, by at least one of the frames and/or packets. As described herein, the one or more frames or packets may include first information that identifies the frame-originator/sender as a device other than the originator/sender of the one or more frames or packets. As described herein, the one or more frames or packets may additionally or alternatively include second information that communicates, e.g., to the client device, that the wireless communication link between the client device and the unpermitted AP MLD is no longer available.

[0043] One of skill in the art will appreciate that the connection detector **132**, the connection evaluator **134**, the spoofing frame generator **136**, and the network manager station **130** may take a variety of forms, be represented as multiple components, and communicate with any number of sources or components referenced herein and other sources or components. For example, the network manager station **130** may comprise one or more processors operable to receive instructions and process them accordingly, and may be embodied as a single computing device or multiple computing devices communicatively coupled to each other. The network manager station **130** may be implemented as a cloud-based platform or may be distributed across multiple physical locations.

In an embodiment, processing actions performed by the network manager station **130** may be distributed among multiple locations.

[0044] In addition to comprising the connection detector **132**, the connection evaluator **134**, and the spoofing frame generator **136**, the network manager station **130** in typical embodiments further comprises or is communicatively coupled, e.g., via a wired or wireless communication network, to a data repository **140**. The data repository **140** in accordance with one or more embodiments of the disclosure is configured to store or access information including, indicating, or corresponding to one or more of authorized access points **142**, detected connections **144**, and spoofed frames **146**. While illustrated within the network manager station **130**, the connection detector **132**, the connection evaluator **134**, the spoofing frame generator **136**, and/or the data repository **140** may be implemented within any other component within the computing system **100**. In certain implementations, the connection detector **132**, the connection evaluator **134**, the spoofing frame generator **136**, and/or the data repository **140** may be implemented at one or more of a device of the private network **102**, the spectrum analyzer **110**, and the permitted AP MLD **112a**, or in some embodiments implemented at the unpermitted AP MLD **118**.

[0045] As used herein, the authorized AP MLDs **142** may comprise or indicate, for example, a listing of network devices, e.g., operative with or relating to routers, switches, network devices, network address translators, or servers, configured to operate as permitted AP MLDs. Each identification or indication of a network device, e.g., authorized AP MLD, may correspond or relate, for example, to an address or name of the network device, Simple Network Management Protocol (SNMP) data, and/or other device or authentication details. In typical embodiments, the identified or indicated network devices may include one or more of the permitted AP MLDs **112a-112n**. Additionally or alternatively, information stored at the data repository **140**, e.g., may indicate or identify the unpermitted AP MLD **118** as not being one of the plurality of permitted AP MLDs indicated or identified by the authorized AP MLDs **142**.

[0046] As used herein, the detected connections **144** may describe, comprise, or reference information indicating, for example, connections or links detected within the wireless environment **108**. The detected connections **144** may correspond to or include information related to or created by the connection detector **132** and/or by the connection evaluator **134**. In certain embodiments, the connections or links may be detected based on the signal information and/or may specify or indicate one or more connections, e.g., links between one or more AP MLDs and one or more client devices. The one or more connections or links may correspond to wireless connections or wireless communication links detected, analyzed, and/or evaluated by the connection detector **132** and/or by the connection evaluator **134**. In one or more embodiments the detected connections **144** identify wireless connections or links detected between AP MLDs and client devices within or corresponding to the wireless environment **108**.

[0047] As used herein, the spoofed frames **146** may include, for example, frames, multi-link elements, and/or packets as described, referenced, indicated by, or corresponding to the in-progress IEEE 802.11be specification and/or the Wi-Fi Alliance related or corresponding developments for WiFi 7 certification. Additionally or alternatively, the spoofed frames **146** may include or reference parts of the frames and/or packets. In particular examples, at least a portion of a management frame, e.g., a WiFi 7 management frame, is included or referenced in the spoofed frames **146**. The management frame, as referred to herein, includes any type of frame with a reconfiguration multi-link element indicating that a communication link is no longer available. Additionally or alternatively, the spoofed frames **146** include or reference at least a portion of data of the management frame or at least a portion of data relating to the management frame. In one or more embodiments, the management frame may comprise a multi-link element, e.g., multi-link frame, comprising a plurality of fields that include a “multi-link control” field. The multi-link control field of the plurality of fields may comprise a plurality of subfields that include a “type” subfield. The type subfield of the plurality of subfields may include a value, e.g., 2, configured to indicate that

the type is a reconfiguration type. According to an aspect of the disclosure, setting the type subfield to include the value 2 configures the multi-link element to operate as a reconfiguration multi-link element.

[0048] It is contemplated that the data repository **140** may store any information that can be stored in a computer-storage device or system, such as user-derived data, computer usable instructions, software applications, or other information. Information stored at the data repository **140** may be implemented across any of components, modules, or elements within the computing system **100**. In the illustrated embodiment, for purposes of clarity and explanation, this information is shown and described as being stored or residing in relation to or with the data repository **140**.

[0049] In some embodiments, the data repository **140** may cooperate (e.g., directly or via one or more network communication paths or communication links) with other modules or components, for example, to enable the disclosed aspects or in connection with performance of operations described herein. As used in this and the above paragraph, cooperation with or by the data repository **140** may include: retrieving data or enabling access to data, creating data or enabling creation of data, and writing data or enabling writing of data at or by the data repository **140**. In certain embodiments, the data repository **140** is populated with information from a variety of sources and/or systems.

[0050] It is contemplated that the data repository **140** may store any information that can be stored in a computer-storage device or system, such as user-derived data, computer usable instructions, software applications, or other information. Information stored at the data repository **140** may be implemented across any of components, modules, or elements within the operating environment **108**. In the illustrated embodiment, for purposes of clarity and explanation, this information is shown and described as being stored or residing in relation to or with the data repository **140**.

3. TERMINATING A LINK WITH AN ACCESS POINT MULTI-LINK DEVICE (AP MLD)

[0051] FIG. **2** shows an example set of operations for terminating a prohibited wireless communication link between a client device and an unpermitted AP MLD in accordance with embodiments of the disclosure. One or more operations illustrated in FIG. **2** may be modified, rearranged, or omitted altogether in certain aspects. Accordingly, the particular sequence of operations illustrated in FIG. **2** should not be construed as limiting the scope of one or more embodiments of the disclosure.

[0052] The operations may be performed at components within the computing system **100** to effectuate termination of a first wireless communication link between a client device and an unpermitted AP MLD in accordance with one or more embodiments of the disclosure. In certain embodiments of the disclosure, all or portions of one or more of the operations may correspond to, e.g., be performed by, hardware and/or software configured to perform the operations. For instance, a portion or all of the operations may be initiated by the network manager station **130** to effectuate termination of the first wireless communication link between the client device **122** and the unpermitted AP MLD **118** in accordance with certain embodiments of the disclosure. Additionally or alternatively, any part or all of the operations elucidated with reference to the figure may be performed, for example, by the network manager station **130** to cause termination of the first wireless communication link between the client device **122** and the unpermitted AP MLD **118**.

[0053] At Operation **202**, an AP MLD that is prohibited from connecting to a client device in a wireless environment is identified. Identifying an AP MLD that is prohibited from connecting to the client device in the wireless environment may comprise, for example, determining that the client is an authorized client of a specific network and determining that the AP MLD is not an authorized AP of that network, and thus, is not authorized to connect to the client device. According to an aspect of the disclosure, identifying that the AP MLD is prohibited from connecting to the client device in the wireless environment may comprise, for example, determining that the AP MLD is not permitted from connecting, e.g., linking, with the client device. Additionally or alternatively, the AP MLD may be identified as not being permitted to connect via the first wireless

communication link to the client device. For example, the network manager station **130**, and/or in particular one or more of the connection detector **132** of the network manager station **130** and the connection evaluator **134** of the network manager station **130**, may detect the unpermitted AP MLD **118**. For instance, the connection detector **132** and/or the connection evaluator **134** may detect the unpermitted AP MLD **118**, e.g., based on wireless signals **124x** emanating from or being sent to the unpermitted AP MLD **118**. Based on detecting the unpermitted AP MLD **118**, the network manager station **130** may determine that the unpermitted AP MLD **118** is prohibited from connecting to the client device **122**. For instance, the connection evaluator **134** of the network manager station **130** may determine that the unpermitted AP MLD **118** is prohibited from connecting to the client device **122**. Additionally or alternatively, determining that the unpermitted AP MLD **118** is prohibited from connecting to the client device **122** may be based on the authorized AP MLDs **142** at the data repository **140** and/or may be based on the information stored at the data repository **140** indicating or identifying the unpermitted AP MLD **118** as not being one of the plurality of permitted AP MLDs indicated or identified by the authorized AP MLDs **142**.

[0054] At Operation **204**, the unpermitted AP MLD is determined to be connected to the client device over the first wireless communication link. For instance, following a multi-link setup or association process, one or more communication links, e.g., channels, may be established between the client device and the unpermitted AP MLD. A system component, e.g., the network manager station **130**, may determine that a communication link, e.g., the first wireless communication link, between the client device and the unpermitted AP MLD is impermissible. For example, the network manager station **130**, and/or in particular the connection evaluator **134** of the network manager station **130**, may determine that the unpermitted AP MLD **118** is connected to the client device **122** through the first wireless communication link. Determining that the unpermitted AP MLD **118** is connected to the client device **122** via the first wireless communication link may be based on detecting and analyzing one or both of the wireless signals **124x** emanating from or being sent to the unpermitted AP MLD **118** and the wireless signals **124z** emanating from or being sent to the client device.

[0055] Based on or in response to determining that the communication link is impermissible, the network manager station **130** may cause transmission from a device different than the unpermitted AP MLD **118** of a frame. The frame may include information of or corresponding to any of the content stored with or referenced by the spoofing frames **146** and/or the spoofing frame generator **136**. In certain embodiments of the disclosure, the frame may operate as or comprise a management frame. In certain embodiments, the frame is fashioned to indicate or comprise information that is configured to or that operates to spoof the frame-originator as the AP MLD. In one or more implementations, the frame when received and processed by the client device spoofs the frame-originator as the AP MLD by identifying the AP MLD as a source of the frame. In an implementation, the frame spoofs the frame-originator as the AP MLD by identifying the AP MLD as the sender, e.g., transmitter, of the frame.

[0056] At Operation **206**, a frame is caused to be transmitted to the client device in order to cause, e.g., instruct, the client device to terminate the first wireless communication link between the client device and the unpermitted AP MLD **118**. For instance, the frame may be caused by the network manager station **130** to be sent via a beacon transmission protocol or by way of a probe response transmission protocol. Additionally or alternatively, the frame may be caused to be sent by an AP MLD such as the permitted AP MLD **112a** by way of a beacon transmission or by way of a probe response transmission. In certain embodiments of the disclosure, an AP MLD such as the permitted AP MLD **112a** may broadcast and/or send at least one probe response, e.g., responsive to one or more particular events, for receipt and use by the client device **122**. For instance, the one or more particular events may comprise a probe request or other type of request from a device such as the client device **122**. In an embodiment, the probe response may comprise a unicast message.

[0057] The frame caused to be transmitted to the client device may be configured to cause

termination of the first wireless communication link between the client device and the unpermitted AP MLD. In certain embodiments, the frame caused to be transmitted to the client device is configured to instruct the client device to terminate the first wireless communication link between the client device and the unpermitted AP MLD. The frame may comprise, for instance, a management frame, e.g., similar to or corresponding to a management frame or element described or referenced by IEEE 802.11be and/or WiFi 7 specifications, documents, or information.

[0058] In accordance with one or more embodiments, the management frame may include first information that identifies the frame-originator as an entity other than the originator and/or other than a sender of the management frame. In an aspect of the disclosure, the first information may comprise a source identifier that identifies the unpermitted AP MLD device as a source device of the management frame. In typical embodiments, the management frame is transmitted to the client device from a device other than, e.g., different from, the unpermitted AP MLD yet identifies the frame-originator as the unpermitted AP MLD. For example, the management frame may be transmitted to the client device **122** from the permitted AP MLD **112a** and may identify the unpermitted AP MLD **118** as the originator or sender of the management frame. By identifying the frame-originator as an entity other than the frame-originator (e.g., different than the permitted AP MLD **112a**), the management frame may operate to spoof the identity of the frame-originator as the unpermitted AP MLD **118**.

[0059] In accordance with an additional or alternative aspect of the disclosure, the management frame may include second information that is operative to communicate or specify, e.g., to the client device, that the first wireless communication link between the client device and the AP MLD is no longer available. According to one or more embodiments of the disclosure, the second information may indicate to the client device **122** that the first wireless communication link between the client device **122** and the unpermitted AP MLD **118** is no longer available. According to a particular aspect of the disclosure, the second information may comprise a reconfiguration multi-link element specifying that the first wireless communication link between a client device receiving the second information and an unpermitted AP MLD related to the first wireless communication link is no longer available.

[0060] In addition to identifying the frame-originator as the unpermitted AP MLD, the management frame may identify the client device as a destination for the frame. The client device receives and processes the management frame as if the management frame were transmitted by the unpermitted AP MLD. As a consequence of the client device receiving the management frame and of the management frame containing the reconfiguration multi-link element (indicating that the communication link is no longer available), the client device terminates the communication link specified by the management frame.

[0061] In certain embodiments, the first wireless communication link is one of a plurality of wireless communication links corresponding to the unpermitted AP MLD. The reconfiguration multi-link element may indicate that a second wireless communication link, which connects the unpermitted AP MLD and the client device, is no longer available. Additionally or alternatively, when the first wireless communication link is one of a plurality of wireless communication links established between the client device and the AP MLD, the frame may indicate that each of the plurality of wireless communication links are no longer available. Additionally or alternatively, the client device may terminate each of the plurality of wireless communication links in response to receiving the frame.

[0062] In one or more additional or alternative implementations, the frame may include an unencrypted frame and/or an unencrypted probe response frame. Transmitting the unencrypted frame or the unencrypted probe response frame may cause the client device to terminate the prohibited wireless communication link. In additional or alternative embodiments, the frame may include one or both of an unencrypted frame and an unencrypted beacon frame. The transmission of the unencrypted frame or the unencrypted beacon frame may cause the client device to terminate

the prohibited wireless communication link.

4. EXAMPLE EMBODIMENT

[0063] A detailed example is described below for purposes of clarity. Components and/or operations described below should be understood as specific examples which may not be applicable to certain embodiments. Accordingly, components and/or operations described below should not be construed as limiting the scope of any of the claims.

[0064] FIGS. 3A-3D depict an example implementation of terminating a first wireless communication link between a client device and an unpermitted AP MLD in accordance with one or more embodiments of the disclosure. Like elements in the figures, e.g., with respect to FIGS. 1A-1B and FIGS. 3A-3D, are referred to with and using like reference numeral indicators. FIGS. 3A-3D illustrate a particular computing system and sequence of operations for terminating a first wireless communication link by transmitting a spoof management frame. The example implementation depicts a wireless environment **300** that includes or corresponds to a first enterprise wireless communication network and a second enterprise wireless communication network.

[0065] The first enterprise wireless communication network may correspond to a first commercial entity, e.g., Coffee Shop **350**. The first commercial entity, e.g., Coffee Shop **350**, may comprise the unpermitted AP MLD **318**. In the illustrated example, the unpermitted AP MLD **318** may comprise a corresponding set of radios including a Radio A **320a** and a Radio N **320n**. The Radio A **320a** and the Radio N **320n** may transmit and receive wireless communication signals **324x**.

[0066] The second enterprise wireless communication network may correspond to a second commercial entity, e.g., Scranton Paper Company **360**. The second commercial entity, e.g., Scranton Paper Company **360**, may comprise multiple AP MLDs such as the permitted AP MLD **312a** and a permitted AP MLD **312n**. Further, the permitted AP MLD **312a** and the permitted AP MLD **312n** may comprise a first set of radios including a Radio A **314a** and a Radio N **314n** and a second set of radios including a Radio A **316a** and a Radio N **316n**, respectively. For example, the Radio A **314a** and the Radio N **314n** may transmit and receive wireless communication signals **324a**, and the Radio A **316a** and the Radio N **316n** may transmit and receive wireless communication signals **324n**.

[0067] Further, the second commercial entity, e.g., Scranton Paper Company **360**, in the illustrated implementation may comprise a spectrum analyzer **310** and a network manager station **330**. According to one or more embodiments, the wireless environment **300** comprises a WiFi 7 wireless communications environment, cf., the wireless environment **108**, supporting one or more multi-link enabled client devices, such as one or more tablets or smartphones. The one or more client devices are enabled to access multiple wireless links or channels, e.g., via at least a portion of the plurality of AP MLDs, at or near a same time. For example, an MLO paradigm implemented within the wireless environment **360** may allow a client device **322** to connect to both a first link or channel, e.g., a 5-GHz wireless channel, and a second link or channel, e.g., a 6-GHz wireless channel. The first link or channel and the second link or channel may be offered, for example, by one or more of the plurality of AP MLDs for use, e.g., concurrently, by the client device **322** for wirelessly sending and receiving data.

[0068] In FIG. 3A, a first wireless communication link has been established between the unpermitted AP MLD **318** and the client device **322**. Note that the particular elements participating in a particular wireless communication link in each of FIGS. 3A, 3B, and 3D are shaded in the corresponding drawings. FIG. 3A may correspond, for example, to Operations **202** and **204** in which a prohibited first wireless communication link is detected. FIG. 3B may correspond, for example, to Operation **204** in which a frame is caused to be transmitted. FIG. 3C indicates, e.g., via the lack of shading of elements, that the first wireless communication link has been terminated by virtue of transmitting the frame. In FIG. 3D, a second wireless communication link is established between the permitted AP MLD **312a** and the client device **322**.

[0069] According to an aspect of the disclosure, transmission of the frame comprises sending, e.g.,

via or corresponding to a wireless communication signal **324a**, management frame **324s**, cf. Operation **206**. Based on or after causing the transmission, one or more components for detecting wireless signals, e.g., spectrum analyzer **310** or network manager station **330**, may obtain network information from or relating to the wireless environment **300**. The network information may include link information. In certain embodiments, the one or more signal detection components may conduct monitoring operations, and/or receive, link information after the causing of or initiating transmission of the management frame **324s**. The link information may indicate or specify, for example, whether or not the first wireless communication link between the unpermitted AP MLD **318** and the client device **322** has been terminated. In an example implementation, the indication or specification of whether or not the first wireless communication link has been terminated may comprise, for example, spectrum information and/or analysis signals generated by the spectrum analyzer **310** (e.g., based on spectrum-related information detected at the spectrum analyzer **310**).

[0070] In one or more embodiments, the spectrum information and analysis signals generated by the spectrum analyzer **310** correspond to wireless communications between the unpermitted AP MLD **318** and the client device **322** (e.g., detected at and analyzed by the spectrum analyzer **310**). For example, the spectrum analyzer **310** may detect and/or analyze particular spectrum information corresponding to first wireless signals **324x** transmitted by the unpermitted AP MLD **318** within the wireless environment **108** and/or corresponding to second wireless signals **324z** transmitted by client device **322** within the wireless environment **108**. For instance, based on detecting and analyzing spectrum information corresponding to the first wireless signals **324x** and/or the second wireless signals **324z**, the spectrum analyzer **310** may generate and/or transmit, e.g., to the network manager station **330**, analysis signals.

[0071] In example implementations, the analysis signals are transmitted from the spectrum analyzer **310** to one or more recipient components such as the network manager station **330**, a connection detector of the network manager station **330** (cf. connection detector **132**), and/or a connection evaluator of the network manager station **330** (cf. connection evaluator **134**). Additionally or alternatively, the one or more recipient components may comprise, for example, the permitted AP MLD **312a** and/or the permitted AP MLD **312n**. The one or more recipient components may, in some embodiments, use the analysis signals to determine whether or not the first wireless communication link between the unpermitted AP MLD **318** and the client device **322** has been terminated.

[0072] In addition to or as an alternative to the one or more signal detection components monitoring for the link information (indicative of whether or not the first wireless communication link has been terminated), the one or more signal detection components and/or other components may monitor for and/or may receive other link information after the causing of or initiating transmission of the management frame **324s**. The other link information may indicate or specify, for example, whether or not the client device **322** has received and/or has responded to the management frame **324s** that was initiated or caused to be transmitted to the client device **322**. In an example implementation, the indication or specification of whether or not the client device **322** has received and/or responded to the management frame **324s** may comprise content generated by the spectrum analyzer **310** based on spectrum data (e.g., related to the second wireless signals **324z**) detected at the spectrum analyzer **310**.

[0073] Additionally or alternatively, the indication or specification of whether or not the client device **322** has received and/or responded to the management frame **324s** may comprise a signal or message (e.g., related to the second wireless signals **324z** and/or sent via a wired connection) from the client device **322** indicating that the client device **322** has received and/or responded to the management frame **324s**. Responding to the management frame **324s**, in one or more examples, may comprise a transmission from the client device **322** to the unpermitted AP MLD **318** of a particular signal or message. The particular signal or message sent or communicated to the

unpermitted AP MLD **318** may indicate, and/or be determined (e.g., by the one or more other components) to indicate, to the unpermitted AP MLD **318** termination of the first wireless communication link. In typical embodiments, termination of the first wireless communication link comprises or results in the unpermitted AP MLD **318** disassociating with the client device **322**. Additionally, or alternatively, termination of the first wireless communication link may comprise or result in a Basic Service Set (BSS) transition management (BTM) process indicating the unpermitted AP MLD **318** as not being an affiliated AP MLD for the client device **322**.

[0074] In an example implementation, the particular signal or message may comprise or indicate a termination frame indicating termination of the first wireless communication link and/or that the client device **322** does not intend to and will not communicate further, e.g., will not associate with and/or form another wireless communication link, with the unpermitted AP MLD **318**. Hence, the other link information may indicate or specify whether or not the client device **322** has sent a link-termination message (instructing that the first wireless communication link be terminated) to the unpermitted AP MLD **318** in response to the management frame **324s**.

[0075] According to an aspect of the disclosure, one or more components at or corresponding to the second commercial entity, e.g., Scranton Paper Company **360**, may determine whether causing or initiating transmission of the management frame **324s** has been effective. For example, the network manager station **330**, and/or in particular the connection evaluator of the network manager station **330**, may determine whether causing or initiating transmission of the management frame **324s** to the client device **322** has resulted in the first wireless communication link between the client device **322** and the unpermitted AP MLD **318** being terminated. If for example, one or more conditions are not detected, then an additional measure or measures may be implemented. The one or more conditions may include the first wireless communication link between the unpermitted AP MLD **318** and the client device **322** not being determined to have been terminated, e.g., based on the link information, and/or the client device **322** not having been determined to have responded to the management frame **324s**, e.g., based on the other link information. In one or more embodiments, the additional measure or measures may be implemented if the one or more conditions have not been detected following a pre-set interval of time following transmission of the management frame **324s**.

[0076] In an example embodiment, the pre-set interval of time is set by or corresponds to a disassociation timer stored and/or used by the network manager station **330**. The one or more additional measures may include, for example, initiating one or more notifications, e.g., to the client device **322** and/or to the enterprise affiliated with the client device **322**. The one or more notifications may indicate a BSS Termination corresponding to the first wireless communication link between the client device **322** and the unpermitted AP MLD **318** is being terminated. The notification may comprise, for example, one or more BSS Termination frames sent, for example, by the network manager station **330** and/or by the permitted AP MLD **312a**.

5. HARDWARE OVERVIEW

[0077] According to one embodiment of the disclosure, the techniques described herein are implemented by one or more special-purpose computing devices. The special-purpose computing devices may be hard-wired to perform the techniques, or may include: (i) digital electronic devices such as one or more application-specific integrated circuits (ASICs), field programmable gate arrays (FPGAs), or network processing units (NPUs) that are persistently programmed to perform the techniques, or (ii) one or more general purpose hardware processors programmed to perform the techniques pursuant to program instructions in firmware, memory, other storage, or a combination. Such special-purpose computing devices may also combine custom hard-wired logic, ASICs, FPGAs, or NPUs with custom programming to accomplish the techniques. The special-purpose computing devices may be desktop computer systems, portable computer systems, handheld devices, networking devices or any other device that incorporates hard-wired and/or program logic to implement the techniques.

[0078] For example, FIG. 4 is a block diagram illustrating the computer system 400 upon which an embodiment of the disclosure may be implemented. Computer system 400 includes a bus 402 or other communication mechanism for communicating information, and a hardware processor 404 coupled with bus 402 for processing information. Hardware processor 404 may be, for example, a general purpose microprocessor.

[0079] Computer system 400 also includes a memory 406, such as a random access memory (RAM) or other dynamic storage device, coupled to bus 402 for storing information and instructions to be executed by processor 404. Memory 406 also may be used for storing temporary variables or other intermediate information during execution of instructions to be executed by processor 404. Such instructions, when stored in non-transitory storage media accessible to processor 404, render computer system 400 into a special-purpose machine that is customized to perform the operations specified in the instructions.

[0080] Computer system 400 further includes a read only memory (ROM) 408 or other static storage device coupled to bus 402 for storing static information and instructions for processor 404. A storage device 410, such as a magnetic disk, flash drive, or optical disk, is provided and coupled to bus 402 for storing information and instructions.

[0081] Computer system 400 may be coupled via bus 402 to a display 412, such as a cathode ray tube (CRT), for displaying information to a computer user. An input device 414, including alphanumeric and other keys, is coupled to bus 402 for communicating information and command selections to processor 404. Another type of user input device is cursor control 416, such as a mouse, a trackball, or cursor direction keys for communicating direction information and command selections to processor 404 and for controlling cursor movement on display 412. This input device typically has two degrees of freedom in two axes, an axis (e.g., x) and another axis (e.g., y), that allows the device to specify positions in a plane.

[0082] Computer system 400 may implement the techniques described herein using customized hard-wired logic, one or more ASICs or FPGAs, firmware and/or program logic which in combination with the computer system causes or programs computer system 400 to be a special-purpose machine. According to one embodiment of the disclosure, the techniques herein are performed by computer system 400 in response to processor 404 executing one or more sequences of one or more instructions contained in memory 406. Such instructions may be read into memory 406 from another storage medium, such as storage device 410. Execution of the sequences of instructions contained in memory 406 causes processor 404 to perform the process operations described herein. In alternative embodiments of the disclosure, hard-wired circuitry may be used in place of or in combination with software instructions.

[0083] The term “storage media” as used herein refers to any non-transitory media that store data and/or instructions that cause a machine to operate in a specific fashion. Such storage media may comprise non-volatile media and/or volatile media. Non-volatile media includes, for example, optical or magnetic disks or flash drives, such as storage device 410. Volatile media includes dynamic memory, such as memory 406. Common forms of storage media include, for example, a floppy disk, a flexible disk, hard disk, solid state drive, magnetic tape, or any other magnetic data storage medium, a CD-ROM, any other optical data storage medium, any physical medium with patterns of holes, a RAM, a PROM, and EPROM, a FLASH-EPROM, NVRAM, any other memory chip or cartridge, content-addressable memory (CAM), and ternary content-addressable memory (TCAM).

[0084] Storage media is distinct from but may be used in conjunction with transmission media. Transmission media participates in transferring information between storage media. For example, transmission media includes coaxial cables, copper wire and fiber optics, including the wires that comprise bus 402. Transmission media can also take the form of acoustic or radio waves, such as those generated during radio-wave and infra-red data communications.

[0085] Various forms of media may be involved in carrying one or more sequences of one or more

instructions to processor **404** for execution. For example, the instructions may initially be carried on a magnetic disk or solid state drive of a remote computer. The remote computer can load the instructions into its dynamic memory and send the instructions over a telephone line using a modem. A modem local to computer system **400** can receive the data on the telephone line and use an infra-red transmitter to convert the data to an infra-red signal. An infra-red detector can receive the data carried in the infra-red signal and appropriate circuitry can place the data on bus **402**. Bus **402** carries the data to memory **406**, from which processor **404** retrieves and executes the instructions. The instructions received by memory **406** may optionally be stored on storage device **410** either before or after execution by processor **404**.

[0086] Computer system **400** also includes a communication interface **418** coupled to bus **402**.

[0087] Communication interface **418** provides a two-way data communication coupling to a network link **420** that is connected to a local network **422**. For example, communication interface **418** may be an integrated services digital network (ISDN) card, cable modem, satellite modem, or a modem to provide a data communication connection to a corresponding type of telephone line. As another example, communication interface **418** may be a local area network (LAN) card to provide a data communication connection to a compatible LAN. Wireless links may also be implemented. In any such implementation, communication interface **418** sends and receives electrical, electromagnetic or optical signals that carry digital data streams representing various types of information.

[0088] Network link **420** typically provides data communication through one or more networks to other data devices. For example, network link **420** may provide a connection through local network **422** to a host computer **424** or to data equipment operated by an Internet Service Provider (ISP) **426**. ISP **426** in turn provides data communication services through the world wide packet data communication network now commonly referred to as the "Internet" **428**. Local network **422** and Internet **428** both use electrical, electromagnetic or optical signals that carry digital data streams. The signals through the various networks and the signals on network link **420** and through communication interface **418**, which carry the digital data to and from computer system **400**, are example forms of transmission media.

[0089] Computer system **400** can send messages and receive data, including program code, through the network(s), network link **420** and communication interface **418**. In the Internet example, a server **430** might transmit a requested code for an application program through Internet **428**, ISP **426**, local network **422** and communication interface **418**.

[0090] The received code may be executed by processor **404** as it is received, and/or stored in storage device **410**, or other non-volatile storage for later execution.

6. MISCELLANEOUS; EXTENSIONS

[0091] Unless otherwise defined, all terms (including technical and scientific terms) are to be given their ordinary and customary meaning to a person of ordinary skill in the art, and are not to be limited to a special or customized meaning unless expressly so defined herein.

[0092] Embodiments are directed to a computing system with one or more devices that include a hardware processor and that are configured to perform any of the operations described herein and/or recited in any of the claims below.

[0093] In an embodiment of the disclosure, one or more non-transitory computer readable storage media comprise instructions which, when executed by one or more hardware processors, cause performance of any of the operations described herein and/or recited in any of the claims.

[0094] Any combination of the features and functionalities described herein may be used in accordance with one or more embodiments of the disclosure. In the foregoing specification, embodiments of the disclosure have been described with reference to numerous specific details that may vary from implementation to implementation. The specification and drawings are, accordingly, to be regarded in an illustrative rather than a restrictive sense. The sole and exclusive indicator of the scope of the disclosure, and what is intended by the applicant to be the scope of the disclosure,

is the literal and equivalent scope of the set of claims that issue from this application, in the specific form in which such claims issue, including any subsequent correction.

Claims

1. One or more non-transitory media having instructions which, when executed by one or more processors, cause a plurality of operations, the operations comprising: upon determining that an AP MLD prohibited from connecting to a client device is connected to the client device over a first wireless communication link: causing a communication from the AP MLD to be spoofed by transmitting, from a device different than the AP MLD, a frame comprising (a) a source identifier that identifies the AP MLD as a source device of the frame and (b) a reconfiguration multi-link element indicating that the first wireless communication link is no longer available, wherein the client device terminates the first wireless communication link in response to receiving the frame.
2. The one or more non-transitory media of claim 1, wherein the frame further comprises (c) a destination identifier that identifies the client device as a destination device.
3. The one or more non-transitory media of claim 1, wherein the operations further comprise determining that the first wireless communication link is impermissible, and wherein causing the communication from the AP MLD to be spoofed is further responsive to the determining that the first wireless communication link is impermissible.
4. The one or more non-transitory media of claim 1, wherein the first wireless communication link is one of a plurality of wireless communication links corresponding to the AP MLD.
5. The one or more non-transitory media of claim 1, wherein the reconfiguration multi-link element further indicates that a second wireless communication link, which connects the AP MLD and the client device, is no longer available.
6. The one or more non-transitory media of claim 1, wherein the first wireless communication link is one of a plurality of wireless communication links established between the client device and the AP MLD, wherein the frame indicates that each of the plurality of wireless communication links are no longer available, and wherein the client device terminates each of the plurality of wireless communication links in response to receiving the frame.
7. The one or more non-transitory media of claim 1, wherein the frame includes an unencrypted frame.
8. The one or more non-transitory media of claim 1, wherein the frame includes an unencrypted beacon frame.
9. The one or more non-transitory media of claim 1, wherein the frame includes an unencrypted probe response frame.
10. A system having one or more processors configured to facilitate a plurality of operations, the operations comprising: determining that an AP MLD, prohibited from connecting to a client device, is connected to the client device over a first wireless communication link; and based on the determining, spoofing a communication from the AP MLD by causing transmission, from a device different than the AP MLD, of a frame comprising: a source identifier indicating the AP MLD as a source device of the frame; and a reconfiguration multi-link element indicating that the first wireless communication link is no longer available, wherein the frame is configured to cause the client device to terminate the first wireless communication link.
11. The system of claim 10, wherein the frame further comprises a destination identifier configured to identify the client device as a destination device.
12. The system of claim 10, wherein spoofing the communication from the AP MLD is responsive further to a determination, by the one or more processors, that the first wireless communication link is impermissible.
13. The system of claim 10, wherein the first wireless communication link is one of a plurality of wireless communication links corresponding to the AP MLD, and wherein the reconfiguration

multi-link element further indicates that a second wireless communication link, that connects the AP MLD and the client device, is no longer available.

14. The system of claim 10, wherein the first wireless communication link is one of a plurality of wireless communication links established between the client device and the AP MLD, and wherein the frame indicates termination of each of the plurality of wireless communication links.

15. The system of claim 14, wherein the frame includes an unencrypted frame, and wherein the client device terminates each of the plurality of wireless communication links in response to receiving the unencrypted frame.

16. A method, comprising: in response to determining a prohibited wireless communication link between an AP MLD and a client device, generating a frame comprising: a source identifier and a reconfiguration multi-link element indicating that the AP MLD is a source device of the frame and that the prohibited wireless communication link is no longer available; and causing the frame to be transmitted from a device different than the AP MLD, wherein the transmitting causes the client device to terminate the prohibited wireless communication link.

17. The method of claim 16, further comprising determining that the prohibited wireless communication link is impermissible.

18. The method of claim 16, wherein determining that the prohibited wireless communication link is impermissible is based on stored information indicating the AP MLD is an unauthorized AP MLD, and wherein the frame includes a destination identifier that identifies the client device as a destination device.

19. The method of claim 16, wherein the prohibited wireless communication link is one link of a plurality of wireless communication links corresponding to the AP MLD, and wherein the reconfiguration multi-link element further indicates: that another link of the plurality of wireless communication links, between the AP MLD and the client device, is no longer available.

20. The method of claim 16, wherein: the prohibited wireless communication link is one of a plurality of wireless communication links established between the client device and the AP MLD; the frame indicates that each of the plurality of wireless communication links are no longer available; and the client device terminates each of the plurality of wireless communication links in response to receiving the frame.
