(1) This application claims priority to and the benefit of Korean Patent Application No. 10-2020-0167831, filed on Dec. 3, 2020, in the Korean Intellectual Property Office, the entire content of which is hereby incorporated by reference.

BACKGROUND

1. Field

(2) One or more aspects of embodiments of the present disclosure relate to an organometallic compound, a light-emitting device including the same, and an electronic apparatus including the light-emitting device.

2. Description of the Related Art

(3) Self-emissive light-emitting devices may have wide viewing angles, excellent or suitable contrast, short response times, and/or excellent or suitable brightness, driving voltage, and/or response speed characteristics.

(4) In a light-emitting device, a first electrode may be located on a substrate, and a hole transport region, an emission layer, an electron transport region, and a second electrode may be sequentially formed on the first electrode. Holes provided from the first electrode may move toward the emission layer through the hole transport region, and electrons provided from the second electrode may move toward the emission layer through the electron transport region. Carriers (such as holes and electrons) may recombine in the emission layer to produce excitons. These excitons may transition from an excited state to the ground state to thereby generate light.

Quantum Dot

(257) The emission layer may include a quantum dot.

(258) In the present specification, the term “quantum dot” refers to a crystal of a semiconductor compound, and may include any material capable of emitting light of various emission wavelengths according to the size (e.g., diameter) of the crystal.

(259) A diameter of the quantum dot may be, for example, in a range of about 1 nm to about 10 nm.

(261) In the wet chemical process, a precursor material is mixed with an organic solvent to grow a quantum dot particle crystal. When the crystal grows, the organic solvent naturally acts as a dispersant coordinated on the surface of the quantum dot crystal and controls the growth of the crystal so that the growth of quantum dot particles can be controlled through a process that is more easily performed than vapor deposition methods, (such as metal organic chemical vapor deposition (MOCVD) and/or molecular beam epitaxy (MBE)), and which is a low cost process.

(262) The quantum dot may include a Group II-VI semiconductor compound, a Group III-V semiconductor compound, a Group III-VI semiconductor compound, a Group I-III-VI semiconductor compound, a Group IV-VI semiconductor compound, a Group IV element or compound; or any combination thereof.

(268) The Group IV element or compound may include a single element compound (such as Si and/or Ge); a binary compound (such as SiC and/or SiGe); or any combination thereof.

(269) Each element included in a multi-element compound (such as the binary compound, the ternary compound, and/or the quaternary compound), may exist (e.g., be included) in a particle with a substantially uniform concentration (e.g., concentration distribution) or non-uniform concentration.

(270) In one embodiment, the quantum dot may have a single structure or a dual core-shell structure. The resultant glass substrate was loaded onto a vacuum deposition apparatus.

(438) 2-TNATA was vacuum-deposited on the anode to form a hole injection layer having a thickness of 600 Å, and 4,4'-bis[N-(1-naphthyl)-N-phenylamino] biphenyl (hereinafter referred to as NPB) was vacuum-deposited on the hole injection layer to form a hole transport layer having a thickness of 300 Å.

(439) Compound BD1 (first compound), compound DFD2 (fourth compound), compound ETH66 (second compound), and compound HTH29 (third compound) were vacuum-deposited on the hole transport layer at a weight ratio of 1:0.5:3:6 to form an emission layer having a thickness of 400 Å.

(440) Compound ETH2 was vacuum-deposited on the emission layer to form a hole blocking layer having a thickness of 50 Å, Alq.₃ was vacuum-deposited on the hole blocking layer to form an electron transport layer having a thickness of 300 Å, LiF was vacuum-deposited on the electron transport layer to form an electron injection layer having a thickness of 10 Å, and then, Al was vacuum-deposited thereon to form a cathode having a thickness of 3,000 Å, thereby completing the manufacture of an organic light-emitting device.
