United States Patent	12390383
Kind Code	B2
Date of Patent	August 19, 2025
Inventor(s)	Fowler; Paul M. et al.

---

### Apparatus and system for turning and positioning a patient

---

#### Abstract

A system for use with a bed having a frame and a supporting surface includes a sheet having a bottom surface configured to be placed above the supporting surface and a top surface opposite the bottom surface, and a wedge having a wedge body with a base wall, a ramp surface, and a back wall, wherein the base wall has a base engagement member configured to engage a surface of the bed to form a selective gliding assembly that resists movement of the wedge with respect to the bed in a direction extending from the back wall toward the apex, and wherein the base engagement member is configured as a patch, the patch covering only a first portion of the base wall such that edges of the engagement members are spaced from edges of the base wall to allow a second portion of the base wall to be exposed.

---

**Inventors:** Fowler; Paul M. (Rockford, IL), Golden; Craig S. (Arlington Heights, IL)

**Applicant:** Sage Products, LLC (Cary, IL)

**Family ID:** 1000008767625

**Assignee:** Sage Products, LLC (Cary, IL)

**Appl. No.:** 17/567683

**Filed:** January 03, 2022

## **Background/Summary**

CROSS-REFERENCE TO RELATED APPLICATIONS (1) This application is a divisional of U.S. patent application Ser. No. 15/635,493, filed Jun. 28, 2017, which is a divisional of U.S. patent application Ser. No. 14/555,199, filed Nov. 26, 2014, which claims the benefit of U.S. Provisional Patent Application No. 61/909,654, filed Nov. 27, 2013. All of the aforementioned applications are incorporated herein by reference in their entireties.

### **BACKGROUND**

(1) The present invention generally relates to an apparatus, system, and method for turning and positioning a person on a bed or the like, and, more particularly, to a sheet having a gripping surface, an absorbent pad, and/or a wedge for use in turning and positioning a person, utilizing selective glide assemblies to allow or resist movement of the components of the system in certain directions, as well as systems and methods including one or more of such apparatuses.

(2) Nurses and other caregivers at hospitals, assisted living facilities, and other locations often care for bedridden patients that have limited or no mobility, many of whom are critically ill or injured. These immobile patients are at risk for forming pressure ulcers (bed sores). Pressure ulcers are typically formed by one or more of several factors. Pressure on a patient's skin, particularly for extended periods of time and in areas where bone or cartilage protrudes close to the surface of the skin, can cause pressure ulcers. Frictional forces and shearing forces from the patient's skin rubbing or pulling against a resting surface can also cause pressure ulcers. Excessive heat and moisture can cause the skin to be more fragile and increase the risk for pressure ulcers. One area in which pressure ulcers frequently form is on the sacrum, because a patient lying on his/her back puts constant pressure on the sacrum, and sliding of the patient in a bed can also cause friction and

shearing at the sacrum. Additionally, some patients need to rest with their heads inclined for pulmonary reasons, which can cause patients to slip downward in the bed and cause further friction or shearing at the sacrum and other areas. Existing devices and methods often do not adequately protect against pressure ulcers in bedridden patients, particularly pressure ulcers in the sacral region.

(3) One effective way to combat sacral pressure ulcers is frequent turning of the patient, so that the patient is resting on one side or the other, and pressure is taken off of the sacrum. Pillows that are stuffed partially under the patient are often used to support the patient's body in resting on his or her left or right side. A protocol is often used for scheduled turning of bedridden patients, and dictates that patients should be turned Q2, or every two hours, either from resting at a 30° angle on one side to a 30° angle on the other side, or from 30° on one side to 0°/supine (lying on his/her back) to 30° on the other side. However, turning patients is difficult and time consuming, typically requiring two or more caregivers, and can result in injury to caregivers from pushing and pulling the patient's weight during such turning. As a result, ensuring compliance with turning protocols, Q2 or otherwise, is often difficult. Additionally, the pillows used in turning and supporting the patient are non-uniform and can pose difficulties in achieving consistent turning angles, as well as occasionally slipping out from underneath the patient. Further, patients who are positioned in an inclined position on the bed tend to slide downward toward the foot of the bed over time, which can cause them to slip off of any supporting structures that may be supporting them. Still further, many patient positioning devices cannot be left under a patient for long periods of time, because they do not have sufficient breathability.

(4) The present invention seeks to overcome certain of these limitations and other drawbacks of existing devices, systems, and methods, and to provide new features not heretofore available.

## SUMMARY

(5) The following presents a general summary of aspects of the invention in order to provide a basic understanding of the invention. This summary is not an extensive overview of the invention. It is not intended to identify key or critical elements of the invention or to delineate the scope of the invention. The following summary merely presents some concepts of the invention in a general form as a prelude to the more detailed description provided below.

(6) Aspects of the present disclosure relate to a system for use with a bed having a frame and a supporting surface supported by the frame. The system includes a sheet having a bottom surface configured to be placed above the supporting surface of the bed and a top surface opposite the bottom surface, and a wedge having a wedge body with a base wall, a ramp surface, and a back wall, where the ramp surface is joined to the base wall to form an apex. The wedge is configured to be positioned under the sheet such that the base wall confronts the supporting surface of the bed and the ramp surface confronts the bottom surface of the sheet. The sheet has a sheet engagement member positioned on the bottom surface, and the ramp surface of the wedge has a ramp engagement member. The ramp engagement member is configured to engage the sheet engagement member to form a selective gliding assembly that resists movement of the sheet with respect to the ramp surface in a first direction, such that a first pull force necessary to create sliding movement of the sheet with respect to the ramp surface in the first direction is greater compared to a second pull force necessary to create sliding movement of the sheet with respect to the ramp surface in a second direction that is different from the first direction. The second direction may be transverse to the first direction or opposed to the first direction. For example, the second direction may be at an angle of 90° or 180° to the first direction.

(7) According to one aspect, the ramp surface of the wedge further has a second ramp engagement member that is configured to engage the sheet engagement member to further form the selective gliding assembly to resist movement of the sheet with respect to the ramp surface in a third direction different from the first and second directions. In this configuration, a third pull force necessary to create sliding movement of the sheet with respect to the ramp surface in the third

direction is greater compared to the second pull force. The ramp engagement member and the sheet engagement member may include a directional stitching material, and the second ramp engagement member may include a directional glide material in this configuration. The third direction may also be transverse or opposed to the first and/or second directions. For example, the third direction may be at an angle of 90° or 180° to the first direction. In one configuration, the first direction is parallel to at least one of the apex and the back wall of the wedge, the second direction extends from the apex toward the back wall of the wedge, and the third direction extends from the back wall toward the apex of the wedge.

(8) According to another aspect, the sheet includes a first piece of a first material having a first coefficient of friction and a second material connected to the first piece, the second material having a second coefficient of friction, wherein the second material forms at least a portion of the top surface, and wherein the second coefficient of friction is higher than the first coefficient of friction such that the top surface provides greater slipping resistance in at least one direction, or all directions, as compared to the bottom surface.

(9) According to a further aspect, the sheet also includes a wipeable material covering at least a portion of the top surface of the sheet.

(10) According to yet another aspect, the wedge further includes a base engagement member on the base wall, configured to engage a surface of the bed to form a second selective gliding assembly that resists movement of the wedge with respect to the bed in at least one direction. For example, the second selective gliding assembly may resist movement of the wedge with respect to the bed in a direction extending from the apex toward the back wall of the wedge.

(11) According to a still further aspect, the system may also include a support connected to the wedge and extending from the apex and configured to be positioned under the sheet beneath an upper thigh area of a patient. In this position, a bottom surface of the support confronts the supporting surface of the bed and a top surface of the support confronts the bottom surface of the sheet and the patient. The support may further include a support engagement member configured to engage the sheet engagement member to form a second selective gliding assembly that resists movement of the sheet with respect to the support in a direction extending parallel to at least one of the apex and the back wall of the wedge.

(12) According to an additional aspect, the system may further include a second wedge including any or all of the components and features of the wedge described herein. The two wedges can be simultaneously placed below the patient, with one wedge supporting the upper body of the patient and another wedge supporting the lower body of the patient, leaving space for the patient's sacral area. Additionally, the sheet engagement member may be formed of a first piece of directional stitching material configured to engage the ramp engagement member of the wedge and a second piece of directional stitching material configured to engage the ramp engagement member of the second wedge.

(13) Additional aspects of the disclosure relate to a system for use with a bed having a frame and a supporting surface supported by the frame that includes a sheet having a bottom surface configured to be placed above the supporting surface of the bed, a top surface opposite the bottom surface, a head edge configured to be placed most proximate to a head of the bed, and a foot edge configured to be placed most proximate to a foot of the bed, and a wedge having a wedge body having a base wall, a ramp surface, and a back wall, with the ramp surface joined to the base wall to form an apex. The wedge is configured to be positioned under the sheet such that the base wall confronts the supporting surface of the bed and the ramp surface confronts the bottom surface of the sheet. The bottom surface of the sheet and the ramp surface of the wedge have engagement members forming a selective gliding assembly that resists movement of the sheet with respect to the wedge in a first direction extending from the back wall toward the apex of the wedge and in a second direction extending from the head edge toward the foot edge of the sheet, such that pull forces necessary to create sliding movement of the sheet with respect to the ramp surface in the first and

second directions are greater compared to a third pull force necessary to create sliding of the sheet with respect to the ramp surface in a third direction extending from the apex toward the back wall of the wedge. The system may include any other components and features described herein.

(14) According to one aspect, the selective gliding assembly includes a directional stitching material positioned on the bottom surface of the sheet and the ramp surface of the wedge and a directional glide material also positioned on the ramp surface of the wedge.

(15) According to another aspect, the wedge further includes a base engagement member on the base wall, configured to engage a surface of the bed to form a second selective gliding assembly that is configured to resist movement of the wedge in a direction extending from the apex toward the back wall of the wedge.

(16) According to a further aspect, a support is connected to the wedge and extends from the apex, where the support is configured to be positioned under the sheet in an upper thigh area of a patient. In this configuration, the bottom surface of the support confronts the supporting surface of the bed and a top surface of the support confronts the bottom surface of the sheet and the patient. The support may further include a support engagement member configured to engage the sheet engagement member to form a second selective gliding assembly that resists movement of the sheet in the second direction with respect to the support.

(17) Further aspects of the disclosure relate to a system including a sheet having a bottom surface configured to be placed above the supporting surface of the bed and a top surface opposite the bottom surface, and a wedge having a wedge body having a base wall, a ramp surface, and a back wall, the ramp surface joined to the base wall to form an apex. The wedge is configured to be positioned under the sheet such that the base wall confronts the supporting surface of the bed and the ramp surface confronts the bottom surface of the sheet. The base wall of the wedge has a base engagement member that is configured to engage a surface of the bed to form a selective gliding assembly that resists movement of the wedge with respect to the bed in a direction extending from the back wall toward the apex, such that a first pull force necessary to create sliding movement of the wedge with respect to the surface of the bed in the first direction is greater compared to a second pull force necessary to create sliding movement of the wedge with respect to the surface of the bed in any direction other than the first direction. The system may include any other components and features described herein. For example, the base engagement member may include a directional glide material.

(18) Still further aspects of the disclosure relate to individual components of the systems described herein, including the sheet and/or the wedge(s) having any or all of the features as described herein. For example, aspects of the disclosure relate to a wedge that includes a wedge body formed at least partially of a compressible material, a base wall configured to confront the supporting surface of the bed, a ramp surface joined to the base wall to form an apex, the ramp surface configured for confronting a patient supported by the bed, a back wall extending between the base wall and the ramp surface, and two opposed side walls extending between the base wall, the ramp surface, and the back wall, with a support connected to the wedge and extending outwardly from the apex. The support is configured to be positioned in an upper thigh area of the patient, such that a bottom surface of the support confronts the supporting surface of the bed and a top surface of the support confronts the patient. The wedge may include any other components and features thereof described herein.

(19) According to one aspect, the support includes a directional stitching material on the top surface of the support. Additionally, a directional glide material may be positioned on the ramp surface and on the base surface of the wedge, and the directional stitching material is also positioned on the ramp surface of the wedge. In this configuration, the directional glide material positioned on the base surface may resist movement of the wedge with respect to the supporting surface of the bed in a first direction from the apex toward the back wall of the wedge; the directional glide material positioned on the ramp surface of the wedge may resist movement of another surface (e.g., a sheet

as described herein) with respect to the ramp surface in a second direction from the back wall toward the apex of the wedge; and the directional stitching material positioned on the top surface of the support and the ramp surface of the wedge may resist movement of the other surface with respect to the ramp surface of the wedge or the top surface of the support in a direction extending parallel to at least one of the apex and the back wall of the wedge.

(20) Other aspects of the disclosure relate to a method for use with a system as described herein and/or individual components of such systems. For example, the method may include placing a sheet as described herein above a supporting surface of a bed and beneath a patient positioned on the bed, and inserting a wedge as described herein beneath the sheet and beneath the patient by moving the wedge away from a side edge of the bed and toward and under the patient. After insertion, the ramp surface of the wedge supports the patient in an angled position. The base wall of the wedge has an engagement member that engages a surface of the bed to form a selective gliding assembly that resists movement of the wedge with respect to the surface of the bed in a first direction away from the patient and toward the side edge of the bed, and wherein the selective gliding assembly permits movement of the wedge with respect to the surface of the bed in a second direction from the side edge of the bed toward the patient to ease insertion of the wedge beneath the sheet, such that a first pull force necessary to create sliding movement of the wedge in the first direction is greater compared to a second pull force necessary to create sliding movement of the wedge in the second direction. The sheet (along with the patient) may be pulled slightly toward the side edge of the bed to properly position the patient after insertion of the wedge.

(21) According to one aspect, the bottom surface of the sheet and the ramp surface of the wedge have additional engagement members forming a second selective gliding assembly that resists movement of the sheet with respect to the wedge in the second direction from the side edge of the bed toward the patient and permits movement of the sheet with respect to the wedge in the first direction away from the patient and toward the side edge of the bed, such that a third pull force necessary to create sliding movement of the sheet in the first direction is greater compared to a fourth pull force necessary to create sliding movement of the sheet in the second direction. In this configuration, the second selective gliding assembly further resists movement of the sheet with respect to the wedge in a third direction parallel to the side edge of the bed, such that a fifth pull force necessary to create sliding movement of the wedge in the third direction is greater compared to the fourth pull force.

(22) According to another aspect, the wedge may also include a support as described herein. The method may further include inserting the support under an upper thigh area of the patient by pushing the support beneath the patient.

(23) Other features and advantages of the invention will be apparent from the following description taken in conjunction with the attached drawings.

---

## Description

### BRIEF DESCRIPTION OF THE DRAWINGS

(1) FIG. 1 is an exploded perspective view of one embodiment of a system for use in turning and positioning a patient, according to aspects of the invention;

(2) FIG. 2 is a top elevation view of a flexible sheet of the system of FIG. 1;

(3) FIG. 3 is a bottom perspective view of the flexible sheet of FIG. 2;

(4) FIG. 4 is a bottom perspective view of a wedge of the system of FIG. 1;

(5) FIG. 5 is a top perspective view of the wedge of FIG. 4;

(6) FIG. 6 is a bottom perspective view of a wedge and support of the system of FIG. 1;

(7) FIG. 7 is a top perspective view of the wedge and support of FIG. 6;

(8) FIG. 8 is a top view of a sheet, wedges, and a support of the system of FIG. 1;

- (9) FIG. 9 is a top perspective view of another embodiment of a wedge and support usable in connection with the system of FIG. 1;
- (10) FIGS. 10a-d are a sequential series of views illustrating a method of placing the flexible sheet and an absorbent pad of the system of FIG. 1 on a bed;
- (11) FIGS. 11a-d are a sequential series of views illustrating a method of turning a patient to an angled resting position utilizing the system of FIG. 1, according to aspects of the invention;
- (12) FIG. 12 is a schematic plan view of various selective glide assemblies of the system of FIG. 1, with arrows schematically illustrating directions of free movement and directions of resistance to movement between the components of the system; and
- (13) FIG. 13 is a schematic plan view of one engagement member of a selective glide assembly of the system of FIG. 1.

#### DETAILED DESCRIPTION

(14) While this invention is capable of embodiment in many different forms, there are shown in the drawings, and will herein be described in detail, certain embodiments of the invention with the understanding that the present disclosure is to be considered as an example of the principles of the invention and is not intended to limit the broad aspects of the invention to the embodiments illustrated and described.

(15) In general, the invention relates to one or more apparatuses or devices, including a sheet having a high friction or gripping surface, an absorbent body pad configured to be placed over the sheet, and one or more wedges and a support configured to be placed underneath the sheet to support the patient in various positions where the wedge and the sheet form one or more selective gliding assemblies, as well as systems including one or more of such devices and methods utilizing one or more of such systems and/or devices. Various embodiments of the invention are described below.

(16) Referring now to the figures, and initially to FIGS. 1-8, there is shown an example embodiment of a system 10 for use in turning and positioning a person resting on a surface, such as a patient lying on a hospital bed. As shown in FIG. 1, the system 10 includes a sheet 20, an absorbent body pad 40 configured to be placed over the sheet 20, one or more wedges 50 configured to be placed under the sheet 20, and a support 80 configured to be placed under the sheet 20. The patient can be positioned on top of the body pad 40, with the body pad 40 lying on the sheet 20, and one or more wedges 50 and/or the support 80 optionally positioned underneath the sheet 20.

(17) As shown in FIGS. 8-10d, the system 10 is configured to be placed on a bed 12 or other support apparatus for supporting a person in a supine position. The bed 12 generally includes a frame 14 and a supporting surface 16 supported by the frame 14, as shown in FIGS. 8-10d, and has a head 13, a foot 17 opposite the head 13, and opposed sides or edges 19 extending between the head 13 and the foot 17. The supporting surface 16 can be provided by a mattress 18 or similar structure, and in various embodiments, the mattress 18 can incorporate air pressure support, alternating air pressure support and/or low-air-loss (LAL) technology. These technologies are known in the art, and utilize a pump motor or motors (not shown) to effectuate airflow into, over and/or through the mattress 18. For beds having LAL technology, the top of the mattress 18 may be breathable so that the airflow can pull heat and moisture vapor away from the patient. The bed 12 may also include one or more bed sheets 15 (such as a fitted sheet or flat sheet), as shown in FIGS. 10a-d and 11a-d, as well as pillows, blankets, additional sheets, and other components known in the art. Further, the bed 12 may be an adjustable bed, such as a typical hospital-type bed, where the head 13 (or other parts) of the bed 12 can be raised and lowered, such as to incline the patient's upper body. It is understood that the system 10 and the components thereof can be used with other types of beds 12 as well.

(18) In example embodiments described herein, the apparatus 10 has one or more selective gliding assemblies 60 positioned between components of the apparatus 10 to permit sliding of the

components relative to each other in certain directions and to resist sliding of the components relative to each other in at least one direction. The selective gliding assemblies **60** are formed by one or more directionally-oriented engagement members positioned between the components and configured to engage the components to permit and limit sliding in specified directions.

(19) One type of engagement member that is usable in connection with the apparatus **10** is a stitched material **45** with a directional stitching pattern that extends along a particular direction, such as a herringbone or zig-zag stitching pattern (see FIG. **13**), to assist in allowing the engagement member to glide along one axis and to resist gliding along another axis. As seen in FIG. **13**, the herringbone stitching pattern shown is relatively open, with links **45A** forming angles of 90° or greater, such that each link **45A** in the stitching pattern extends a greater distance along axis A than along axis B. In one embodiment, the links **45A** may form angles of approximately 120°, approximately 110°-180° (straight line), or 90° or greater with respect to each other. Other directional stitching patterns may be utilized, including other directional stitching patterns with links **45A** that are oriented and/or sized differently. In one example, the engagement member **62** may have stitching in the form of a plurality of parallel or substantially parallel lines extending generally a single direction. The directional stitching material **45** as shown in FIG. **13** permits sliding in directions generally along the axis A, or in other words, along the directions in which the stitching pattern extends. The directional stitching material **45** as shown in FIG. **13** resists sliding in directions generally along the axis B, or in other words, across the stitches and/or transverse to the directions in which the stitching pattern extends.

(20) One example of a stitched material usable as the directional stitching material **45** is a loop material (e.g. as used in a hook-and-loop connection), with a directional stitching pattern located on the reverse side of the loop material. This loop material may be connected to a component of the apparatus **10** with the loop side facing inward and the reverse side facing outward to form the surface of the engagement member. The directional stitching material **45** may be formed of a different material in another embodiment, including, without limitation, a variety of different fabric materials. It is understood that such materials may include a directional stitching pattern. The directional stitching material **45** may be connected to a component of the apparatus in a surface-to-surface, confronting relation to form a layered structure in one embodiment, such as by stitching, adhesive, sonic welding, heat welding and other techniques, including techniques familiar to those skilled in the art.

(21) As used in some embodiments described herein, two pieces of a directional stitching material **45**, such as shown in FIG. **12**, can be used in engagement with each other, with the axes A and B of the stitching patterns of the two pieces in alignment, to provide increased resistance to sliding along the axis B. The two pieces of directional stitching material **45** may be the same type of material or different types of material in various embodiments, and may have the same or different stitching patterns. This directional stitching material **45** may also be used in connection with other directionally-oriented engagement members to achieve increased resistance to sliding in selected directions. In various uses, the directional stitching material **45** may have a directional stitching pattern that extends primarily in the lateral or width direction of the apparatus **10** (i.e. between side edges **23**, or primarily in the longitudinal or length direction of the apparatus **10** (i.e. between the front edge **23** and rear edge **23**).

(22) Other materials having directionally oriented textures, patterns, etc., extending in a specified direction may be usable in connection with the apparatus **10** as engagement members. For example, such a material may have a ridged or other textured structure. The directionally oriented texture may have a shape and/or orientation that is similar to one of the embodiments of the directional stitching patterns described above. Such a textured structure may be created by various techniques, including weaving, texturing (e.g. physical deformation), or application of a substance such as by printing, deposition, etc., among other techniques. Such other materials may function in the same manner as the directional stitching material **45** discussed above.

(23) Another type of engagement member that is usable in connection with the apparatus **10** is a directional glide material, such as a brushed fiber material or other brushed fabric material, which may have fibers that lie facing a specific direction. In general, a directional glide material resists gliding in a single direction and permits relatively free gliding in the opposite direction and along an axis perpendicular to the single direction, such that the resistance to gliding in the single direction is significantly higher than any of these three other directions identified. Additionally, a directional glide material may have structural characteristics to create this resistance and freedom for gliding in specific directions, such as structural elements that are directionally oriented. For example, the directional glide material may include projecting structures, e.g., ridges, fibers, bristles, etc., that extend non-perpendicularly from the surface of a substrate, a majority or substantial entirety of which are oriented (e.g., angled, curved, etc.) in the same general direction. One embodiment of an engagement member may be a brushed nylon fiber material (e.g. lint brush material) with about 44-48 wales per inch and about 54-58 courses per inch in one embodiment. Another type of directional glide material may be used in other embodiments, including various ridged fabric and non-fabric materials, such as a flexible ratchet material as used in a zip-tie. The directional glide material may be connected to a component of the apparatus in a surface-to-surface, confronting relation to form a layered structure in one embodiment, such as by stitching, adhesive, sonic welding, heat welding and other techniques, including techniques familiar to those skilled in the art. This directional glide material can be used in connection with a directional stitching material **45** as shown in FIG. **12** to create a selective gliding assembly **60** with a “one-way” glide arrangement. This arrangement allows the engagement members to glide with the grain of the directional glide material, while resisting gliding in other directions, including the opposite direction along the same axis as the gliding direction.

(24) As described herein with respect to the embodiment of FIGS. **1-8**, the apparatus may use selective gliding assemblies **60** to create directional gliding between the wedges **50** and the underside of the sheet **20**, between the wedges **50** and the bed **12**, and between the support **80** and the underside of the sheet **20**. In other embodiments, selective gliding assemblies **60** may be used to create directional gliding between one or more of the above sets of components and/or between one or more other components of the apparatus **10**.

(25) An example embodiment of the sheet **20** of the apparatus is shown in greater detail in FIGS. **2-3**. In general, the sheet **20** is flexible and foldable, and has a top surface **21** and a bottom surface **22** defined by a plurality of peripheral edges **23**. The sheet **20** is configured to be positioned on the bed **12** so that the bottom surface **22** is above the supporting surface **16** of the bed **12** and faces or confronts the supporting surface **16**, and is supported by the supporting surface **16**. As used herein, “above,” “below,” “over,” and “under” do not imply direct contact or engagement. For example, the bottom surface **22** being above the supporting surface **16** means that that the bottom surface **22** may be in contact with the supporting surface **16**, or may face or confront the supporting surface **16** and/or be supported by the supporting surface **16** with one or more structures located between the bottom surface **22** and the supporting surface **16**, such as a bed sheet **15** as described above.

Likewise, “facing” or “confronting” does not imply direct contact or engagement, and may include one or more structures located between the surface and the structure it is confronting or facing.

(26) As seen in FIGS. **2-3**, the sheet **20** in this embodiment is rectangular, having four peripheral edges **23**, but could be a different shape in other embodiments. The top surface **21** has at least a portion formed of a high-friction or gripping material **24**, and the bottom surface **22** has at least a portion formed of a directional stitching material **45**. In this embodiment, the sheet includes a first piece **26** of sheet material that is formed partially or entirely of a low-friction material **25**, with a second piece **27** of sheet material that is formed partially or entirely of the high-friction material **24**, with the second piece **27** connected to the first piece **26** in a surface-to-surface, confronting relation to form a layered structure. The sheet **20** further has one or more additional pieces **46** of sheet material that is formed partially or entirely of the directional stitching material **45**. As

illustrated in FIGS. 2-3, the first piece **26** is larger than the second piece **27**, so that the first piece **26** forms portions of both the top and bottom surfaces **21**, **22** of the sheet **20**, and the second piece **27** forms at least a portion of the top surface **21**, with the edges of the second piece **27** being recessed from the edges **23** of the sheet **20**. Additionally, the one or more additional pieces **46** form at least a portion of the bottom surface **22** of the sheet **20**, with the edges of the additional pieces **46** being recessed from the edges **23** of the sheet. In the embodiment of FIGS. 2-3, the sheet **20** has two additional pieces **46** that are positioned on the bottom surface **22** and are spaced from each other. The second piece **27** may form at least a majority portion of the top surface **21**, and/or the additional piece(s) **46** may form at least a majority portion of the bottom surface **22**, in various embodiments. In other words, in this embodiment, the sheet **20** is primarily formed by the first piece **26**, with the second piece **27** and additional piece(s) **46** connected to the first piece **26** to form at least a part of the top and bottom surfaces **21**. In another embodiment, the first piece **26** may form at least a majority portion of the top and/or bottom surfaces **21**, **22**. The pieces **26**, **27**, **46** are connected by stitching in one embodiment, but may have additional or alternate connections in other embodiments, including adhesives, sonic welding, heat welding and other techniques, including techniques familiar to those skilled in the art.

(27) The low-friction material **25** and/or the high-friction material **24** may be formed by multiple pieces in other embodiments. For example, the first piece **26** made of the low-friction material **25** may have a plurality of strips or patches of the high-friction material **24** connected on the top surface **21** in one embodiment. In a further embodiment, the high friction material **24** may be or include a coating applied to the low friction piece **26**, such as a spray coating. As described in greater detail below, the low-friction material **25** permits sliding of the sheet **20** in contact with the supporting surface **16** of the bed **12**, which may include a fitted bed sheet **15** or other sheet, and the high-friction material **24** provides increased resistance to slipping or sliding of the patient and/or the body pad **40** on which the patient may be lying, in contact with the sheet **20**.

(28) As shown in the embodiment in FIGS. 1-8, the first piece **26** is made substantially entirely of the low-friction material **25**. In one embodiment, the low-friction material **25** is at least partially made from polyester and/or nylon (polyamide), although other materials can be used in addition to or instead of these materials. In one embodiment, the high friction material **24** is a knitted material, which can enhance comfort, and may be made of polyester and/or another suitable material. The material **24** can then be treated with a high friction substance, such as a hot melt adhesive or appropriate plastic, which can be applied as a discontinuous coating to promote breathability. The high-friction and/or low-friction materials **24**, **25** can also be treated with a water repellant, such as polytetrafluoroethylene (PTFE). In other embodiments, the high-friction and/or low-friction materials **24**, **25** may include any combination of these components, and may contain other components in addition to or instead of these components. Additionally, both the first and second pieces **26**, **27** may be breathable in one embodiment, to allow passage of air, heat, and moisture vapor away from the patient.

(29) Generally, the high friction material **24** has a coefficient of friction that is higher than the coefficient of friction of the low friction material **25**. In one embodiment, the coefficient of friction for the high friction material **24** is about 8-10 times higher than the coefficient of friction of the low friction material **25**. In another embodiment, the coefficient of friction for the high friction material **24** is between 5 and 10 times higher, or at least 5 times higher, than the coefficient of friction of the low friction material **25**. The coefficient of friction, as defined herein, can be measured as a direct proportion to the pull force necessary to move either of the materials **24**, **25** in surface-to-surface contact with the same third material, with the same normal force loading. Thus, in the embodiments above, if the pull force for the high friction material **24** is about 8-10 times greater than the pull force for the low friction material **25**, with the same contact material and normal loading, the coefficients of friction will also be 8-10 times different. It is understood that the coefficient of friction may vary by the direction of the pull force, and that the coefficient of friction measured

may be measured in a single direction. For example, in one embodiment, the above differentials in the coefficients of friction of the high friction material **24** and the low friction material **25** may be measured as the coefficient of friction of the low friction material **25** based on a pull force normal to the side edges **23** (i.e. proximate the handles **28**) and the coefficient of friction of the high friction material **24** based on a pull force normal to the top and bottom edges **23** (i.e. parallel to the side edges **23**).

(30) Additionally, the coefficient of friction of the interface between the high-friction material **24** and the pad **40** is greater than the coefficient of friction of the interface between the low friction material **25** and the bed sheet **15** or supporting surface **16**. It is understood that the coefficients of friction for the interfaces may also be measured in a directional orientation, as described above. In one embodiment, the coefficient of friction for the interface of the high friction material **24** is about 8-10 times higher than the coefficient of friction of the interface of the low friction material **25**. In another embodiment, the coefficient of friction for the interface of the high friction material **24** is between 5 and 10 times higher, or at least 5 times higher, than the coefficient of friction of the interface of the low friction material **25**. It is understood that the coefficient of friction for the interface could be modified to at least some degree by modifying factors other than the sheet **20**. For example, a high-friction substance or surface treatment may be applied to the bottom surface **44** of the pad **40**, to increase the coefficient of friction of the interface. An example of a calculation of the coefficients of friction for these interfaces is described below, including a rip-stop nylon material as the low friction material **25** and a knitted material treated with a hot melt adhesive as the high friction material **24**. The relative coefficients of friction of the high friction material **24** and the low friction material **25** are described in greater detail in U.S. Patent Application Publication No. 2012/0186012, published Jul. 26, 2012, which is incorporated by reference herein in its entirety and made part hereof.

(31) In the embodiment of FIGS. **1-8**, the sheet **20** also has a “wipeable” material **47** positioned on at least on the top surface **21** of the sheet **20**. This wipeable material **47** may be formed as a coating on the sheet **20**, such as on the low friction material **25**, in one embodiment. The wipeable material **47** may have various properties, such as smoothness, low tackiness, water repellence, etc., which may facilitate wiping liquid or semi-liquid substances from the material **47**. For example, the wipeable material **47** may be formed by a coating of a silicone material, a urethane material, a silicone-urethane copolymer material, polytetrafluoroethylene (PTFE), or other materials that can create a wipeable surface on the sheet **20**. In another embodiment, the wipeable material **47** may be a separate piece of material that is connected to the sheet **20**, such as by adhesives or other bonding, stitching, fasteners, etc. The wipeable material **47** in the embodiment of FIGS. **1-8** is positioned on the top surface **21** proximate the bottom edge **23** of the sheet **20**, between the high friction material **24** and the bottom edge **23**, which generally corresponds to the area at or below the sacral region of the patient when in the supine position. The absorbent pad **40** may at least partially cover the wipeable material **47** in one configuration, depending on the relative sizes of the sheet **20** and the pad **40**. In other embodiments, the wipeable material **47** may cover a different portion of the top surface **21** and/or may cover portions of other surfaces of the sheet **20**, such as the underside or bottom surface **22**. It is understood that the wipeable material **47** may further be configured to form a barrier to passage of fluids/moisture.

(32) The sheet **20** has one or more engagement members **61** of a selective gliding assembly **60** on the bottom surface **22**, to permit movement of the sheet **20** in desired directions and resist movement of the sheet **20** in undesired directions. In the embodiment of FIGS. **1-8**, the sheet **20** has two engagement members **61** formed as separate patches of directional stitching material **45** (which may be referred to as “sheet engagement members”). In this embodiment, the axis B (along which gliding is resisted) is oriented to extend between the top and bottom edges **23** and parallel to the side edges **23**, and the axis A (along which gliding is allowed) is oriented to extend between the side edges **23** and parallel to the top and bottom edges **23**. Relative to the wedge **50A-B**, the axis B

is oriented to extend parallel to at least one of the apex **55** and the back wall **53** of the wedge and/or between the side walls **54**, and the axis A is oriented to extend between the apex and the back wall of the wedge and/or parallel to the side walls **54**. This arrangement is illustrated schematically in FIG. **12**. In another embodiment, the engagement members **61** may be formed as a single, larger patch or a larger number of patches of the directional stitching material **45**. In a further embodiment, one or more of the engagement members **61** may be formed of a different directionally-oriented material, and/or may be oriented to allow/resist gliding in different directions. For example, if both of the engagement members **61** as depicted in FIGS. **1-8** are turned 90°, then movement in a direction extending between the side edges **23** and parallel to the top and bottom edges **23** would be resisted, and movement in a direction extending between the top and bottom edges **23** and parallel to the side edges **23** would be allowed.

(33) In one embodiment, as illustrated in FIGS. **1-8**, the sheet **20** may also include one or more handles **28**, **48** to facilitate pulling, lifting, and moving the sheet **20**. As shown in FIGS. **2-3**, the sheet **20** has handles **28** formed by strips **29A-B** of a strong material that are stitched in periodic fashion to the bottom surface **22** at or around both side edges **23** of the sheet **20**, as well as the top edge **23** of the sheet. The non-stitched portions can be separated slightly from the sheet **20** to allow a user's hands **76** to slip underneath, and thereby form the handles **28**, as shown in FIG. **3**. The handles **28** formed by the strips **29A** on the side edges **23** of the sheet **20** are useful for pulling the sheet **20** laterally, to move the patient **70** laterally on the bed **12**. The sheet **20** also includes handles **48** in the form of straps that are stitched to the bottom surface **22** of the sheet **20** and extend from the sheet **20**. The handles **48** extend generally outward and toward the top edge **23** of the sheet **20**. In one embodiment, the handles **48** more proximate the top edge **23** of the sheet **20** have a shorter length than the handles **48** more proximate the bottom edge **23** of the sheet **20**. For example, the top-most handles **48** may have a length of about 10 inches, and the bottom-most handles **48** may have a length of about 16 inches, with the length measured from the sheet **20** to the end of the handles **48**. In this configuration, the handles **48** are useful for pulling the sheet **20** toward the head **13** of the bed **12** to “boost” the patient **70** and apparatus **10** if they begin to slide toward the foot **17** of the bed **12**, which may tend to happen especially when the patient **70** is inclined. The handles **28** formed by the strip **29B** on the top edge **23** of the sheet **20** may also be useful for boosting the patient **70** as well. For example, the handles **28** on the top edge **23** of the sheet **20** may be useful when a single caregiver is gripping the sheet to boost the patient **70**. It is understood that the handles **28** formed by strips **29A** on the side edges **23** of the sheet **20** can also be used for “boosting” the patient **70**. Additionally, any of the handles **28**, **48** may be used for rolling the patient right or left, such as in FIGS. **10a-b**. The sheet **20** in FIGS. **1-8** includes four handles **48**, but in other embodiments, a larger or smaller number of handles **48** may be used. In other embodiments, the sheet **20** may include a different number or configuration of the handles **28**, **48** as described above. Further, the handles **28** may be connected to the sheet **20** in a different way, such as by heat welding, sonic welding, adhesive, etc. Other types of handles may be utilized in further embodiments.

(34) The strip **29B** on the top edge **23** of the sheet **20** may further function as a positioning marker to assist in properly positioning the sheet **20** beneath the patient. A positioning marker in this position assists with positioning the sheet **20** beneath the patient when the sheet **20** is rolled or folded up, such as in FIG. **10a**, where the bottom surface **22** of the sheet **20** will be visible. The strip **29B** indicates which edge **23** of the sheet is the top, to avoid the sheet **20** being placed on the bed **12** upside down or sideways. Additionally, the strip **29B** can function as a positioning marker to be aligned with the shoulders of the patient to assist in proper positioning. Other types of positioning markers may be used in other embodiments, including additional markers or other markers that take the place of the strip **29B** or other positioning markers in other positions. It is understood that additional or alternate positioning markers may be used in other embodiments to assist with various aspects of positioning the sheet **20**, such as a marker to indicate proper

alignment with respect to the patient's hips.

(35) In further embodiments, the sheet **20** and the components thereof may have different configurations, such as being made of different materials or having different shapes and relative sizes. For example, in one embodiment, the low-friction material **25** and the high-friction material **24** may be made out of pieces of the same size. In another embodiment, the low-friction material **25** and the high-friction material **24** may be part of a single piece that has a portion that is processed or treated to create a surface with a different coefficient of friction. As an example, a single sheet of material could be treated with a non-stick coating or other low-friction coating or surface treatment on one side, and/or an adhesive or other high-friction coating or surface treatment on the other side. In additional embodiments, the low-friction material **25**, the high-friction material **24**, and the wipeable material **47** may occupy different portions of the sheet **20**, or one or more of these materials may not be present. Still other embodiments are contemplated within the scope of the invention.

(36) In an alternate embodiment, the sheet **20** may not utilize a high friction surface, and instead may utilize a releasable connection to secure the pad **40** in place with respect to the sheet **20**. For example, the sheet **20** and pad **40** may include complementary connections, such as hook-and-loop connectors, buttons, snaps, or other connectors. In a further embodiment, the sheet **20** may be used without a pad **40**, with the patient directly in contact with the top surface **21** of the sheet, and the high-friction material **24** can still resist sliding of the patient on the sheet **20**.

(37) The body pad **40** is typically made from a different material than the sheet **20** and contains an absorbent material, along with possibly other materials as well. The pad **40** provides a resting surface for the patient, and can absorb fluids that may be generated by the patient. The pad **40** may also be a low-lint pad, for less risk of wound contamination, and is typically disposable and replaceable, such as when soiled. The top and bottom surfaces **42**, **44** may have the same or different coefficients of friction. Additionally, the pad **40** illustrated in the embodiments of FIGS. **1** and **10** is approximately the same size as the sheet **20**, and both the sheet **20** and the pad **40** are approximately the same width as the bed **12** so that the edges **23** of the sheet **20** and the edges of the pad **40** are proximate the side edges of the bed **12**, but may be a different size in other embodiments.

(38) In one embodiment, the pad **40** may form an effective barrier to fluid passage on one side, in order to prevent the sheet **20** from being soiled, and may also be breathable, in order to permit flow of air, heat, and moisture vapor away from the patient and lessen the risk of pressure ulcers (bed sores). The sheet **20** may also be breathable to perform the same function, as described above. A breathable sheet **20** used in conjunction with a breathable pad **40** can also benefit from use with a LAL bed **12**, to allow air, heat, and moisture vapor to flow away from the patient more effectively, and to enable creation of an optimal microclimate around the patient. The pad **40** may have differently configured top and bottom surfaces **42**, **44**, with the top surface **42** being configured for contact with the patient and the bottom surface **44** being configured for contact with the sheet **20**.

(39) The system **10** may include one or more wedges **50A-B** that can be positioned under the sheet **20** to provide a ramp and support to slide and position the patient slightly on his/her side, as described below. FIGS. **4-7** illustrate example embodiments of wedges **50A-B** that can be used in conjunction with the system **10**. The wedge **50A-B** has a body **56** that can be triangular in shape, having a base wall or base surface **51**, a ramp surface **52** that is positioned at an oblique angle to the base wall **51**, a back wall **53**, and side walls **54**. In this embodiment, the base wall **51** and the ramp surface **52** meet at an oblique angle to form an apex **55**, and the back wall **53** is positioned opposite the apex **55** and approximately perpendicular to the ramp surface **52**. The apex **55** may be the smallest angle of any of the corners of the wedge **50A-B**, in one embodiment. The side walls **54** in this embodiment are triangular in shape and join at approximately perpendicular angles to the base wall **51**, the ramp surface **52**, and the back wall **53**. In this embodiment, the surfaces **51**, **52**, **53**, **54** of the wedge body **56** are all approximately planar when not subjected to stress, but in other

embodiments, one or more of the surfaces **51**, **52**, **53**, **54** may be curved or rounded. Any of the edges between the surfaces **51**, **52**, **53**, **54** of the wedge body **56** may likewise be curved or rounded, including the apex **55**.

(40) The wedge body **56** in this embodiment is at least somewhat compressible or deformable, in order to provide greater patient comfort and ease of use. Any appropriate compressible material may be used for the wedge body **56**, including various polymer foam materials, such as a polyethylene and/or polyether foam. A particular compressible material may be selected for its specific firmness and/or compressibility, and in one embodiment, the wedge body **56** is made of a foam that has relatively uniform compressibility.

(41) The wedge **50A-B** is configured to be positioned under the sheet **20** and the patient, to position the patient at an angle, as described in greater detail below. In this position, the base wall **51** of the wedge **50A-B** faces downward and engages or confronts the supporting surface **16** of the bed **12**, and the ramp surface **52** faces toward the sheet **20** and the patient and partially supports at least a portion of the weight of the patient. The angle of the apex **55** between the base wall **51** and the ramp surface **52** influences the angle at which the patient is positioned when the wedge **50A-B** is used. In one embodiment, the angle between the base wall **51** and the ramp surface **52** may be up to 45°, or between 15° and 35° in another embodiment, or about 30° in a further embodiment.

Positioning a patient at an angle of approximately 30° is currently clinically recommended, and thus, a wedge **50A-B** having an angle of approximately 30° may be the most effective for use in positioning most immobile patients. If clinical recommendations change, then a wedge **50A-B** having a different angle may be considered to be the most effective. The wedge **50A-B** may be constructed with a different angle as desired in other embodiments. It is understood that the sheet **20** may be usable without the wedges **50A-B**, or with another type of wedge, including any commercially available wedges, or with pillows in a traditional manner. For example, the sheet **20** may be usable with a single wedge **50A-B** having a greater length, or a number of smaller wedges **50A-B**, rather than two wedges **50A-B**, in one embodiment. As another example, two wedges **50A-B** may be connected together by a narrow bridge section or similar structure in another embodiment. It is also understood that the wedge(s) **50A-B** may have utility for positioning a patient independently and apart from the sheet **20** or other components of the system **10**, and may be used in different positions and locations than those described and illustrated herein.

(42) In one embodiment, the wedges **50A-B** may have a directionally-oriented material (e.g., a directional stitching material **45**, directional glide material, etc.) covering at least a portion of the ramp surface **52**, and potentially other surfaces as well. In the embodiments illustrated in FIGS. 4-7, the wedges **50A-B** have the directional stitching material **45** covering the ramp surface **52**. In another embodiment, the directional stitching material **45** may additionally or alternately cover the base wall **51**, the back wall **53**, and/or the side walls **54**. The directional stitching material **45** in this embodiment forms an engagement member **62** (which may be referred to as a “ramp engagement member”), of a selective gliding assembly **60** on at least the ramp surface **52**. In this embodiment, the directional stitching material **45** on the ramp surface **52** has the axis B (along which gliding is resisted) extending between the side walls **54** and parallel to the apex edge **55**, as illustrated in FIG. 12. Accordingly, the axis A (along which gliding is allowed) extends perpendicular to the apex edge **55** and parallel to the side walls **54** in this embodiment, as illustrated in FIG. 12. In this arrangement, the directional stitching material **45** resists movement of the wedges **50A-B** in directions parallel to the ramp surface **52** and perpendicular to the side walls **54**, as described in greater detail herein. Similarly, the directional stitching material **45** resists movement of another surface in contact with the directional stitching material **45** (e.g., the bottom surface **22** of the sheet **20**) relative to the wedges **50A-B** in directions along to the ramp surface **52** (i.e., parallel to the apex **55** and/or the back wall **51**) and perpendicular to the side walls **54**. The directional stitching material **45** also engages the engagement members **61** of the directional stitching material **45** on the bottom surface **22** of the sheet **20** to enhance the selective gliding effect of the selective gliding

assembly. This arrangement is illustrated schematically in FIG. 11d. The other surfaces (e.g., the base wall 51, the back wall 53, and the side walls 54) of the wedges 50A-B are covered by a wrapping material 43 in the embodiment of FIGS. 1-8. This wrapping material 43 may be a taffeta fabric or other suitable material. In another embodiment, one or more of these surfaces may not be covered by any material, so that the inner material of the wedges 50A-B is exposed, or one or more of these surfaces may be partially covered by a material.

(43) In the embodiments illustrated in FIGS. 4-7, the wedges 50A-B also have engagement members 64 in the form of patches of a directional glide material 49 located on one or more surfaces. The wedge 50A illustrated in FIGS. 4-5 has engagement members 64 of the directional glide material 49 located on the ramp surface 52 and the base wall 51 (which may also be referred to as a “ramp engagement member” and a “base engagement member,” respectively). The wedge 50B illustrated in FIGS. 6-7 has an engagement member 64 of the directional glide material 49 located on the ramp surface 52. Each of the engagement members 64 in this embodiment have the directional glide material 49 oriented so that the direction C of allowed movement of another surface with respect to the base wall 51 or the ramp surface 52 extends from the apex 55 toward the back wall 53, as illustrated in FIG. 12. For example, for a brushed nylon fiber material, the fibers would be angled toward the back wall 53, so that gliding over the engagement member 64 in the direction C from the apex 55 toward the back wall 53 is free, while gliding in the opposite direction D from the back wall 53 toward the apex 55 is resisted. It is understood that this gliding is explained above with respect to the movement of another surface in contact with the directional glide material 49 (e.g., the bottom surface 22 of the sheet 20 or the bed sheet 15) relative to the wedge 50A-B. This same directional relationship can alternately be expressed as resisting movement of the wedge 50A-B with respect to the other surface in a direction from the apex 55 toward the back wall 53 (e.g., resisting the wedge 50A-B from moving away from the patient), while allowing free gliding of the wedge 50A-B with respect to the other surface in a direction from the back wall 53 toward the apex 55 (e.g., allowing easy insertion of the wedge 50A-B beneath the sheet 20).

(44) In the embodiments illustrated in FIGS. 4-7, the patches of the directional glide material 49 covered only a portion of the surfaces 51, 52 on which they were located, such that the edges of the directional glide material 49 are spaced from the edges of the respective surfaces on which they are located. In this configuration, the amount of the directional glide material 49 is sufficient to provide good resistance to unwanted slipping, but is not excessively expensive and leaves part of the directional stitching material 45 on the ramp surface 52 exposed to provide further functionality. For example, in one embodiment, the directional glide material 49 may cover approximately 20-40% of the surface area of the respective surface on which it is disposed, and in another embodiment, the directional glide material 49 may cover approximately 25-30% of the respective surface. In other embodiments, the directional glide material 49 may be located, sized, and/or oriented differently, and generally cover at least a portion of the surfaces on which they are located. Additionally, each of the patches of the directional glide material 49 may have a border to help resist abrasion, fraying, and or other wear, as shown in FIGS. 4-7. Such a border may be created by stitching (e.g., serge stitch), addition of a durable material, or other technique. Further, each of the patches of the directional glide material 49 may be connected to the wedge 50A-B by stitching, adhesive or other bonding, and/or other techniques. The engagement members 64 may have other configurations in other embodiments, including using different types of directionally-oriented materials.

(45) As described above, the engagement members 62 of the directional stitching material 45 on the ramp surfaces 52 of the wedges 50A-B engage the engagement members 61 of the directional stitching material 45 on the bottom surface 22 of the sheet 20 to enhance the selective gliding effect of the selective gliding assembly 60. This engagement resists movement of the sheet 20 with respect to the wedges 50A-B along the axis B, and particularly, in the direction from the top edge

**23** to the bottom edge **23** of the sheet **20**, or in other words, from the head **13** to the foot **17** of the bed **12**. In one embodiment, the directional stitching material **45** sliding upon another piece of the same material provides a resistance to sliding along the axis B on both pieces of material that is at least  $3\times$  greater (e.g.,  $3.6\times$  in one embodiment) than the resistance to sliding along the axis A on both pieces of material. In other embodiments, the directional stitching material **45** sliding upon another piece of the same material provides a resistance to sliding along the axis B on both pieces of material that is at least  $2\times$  greater, or at least  $2.5\times$  greater, than the resistance to sliding along the axis A on both pieces of material. These and all other relative measurements of resistance to sliding described herein may be calculated using ASTM D1894. Additionally, the engagement members **64** of the directional glide material **49** engage the engagement members **61** of the directional stitching material **45** on the bottom surface **22** of the sheet **20** to resist movement of the sheet **20** with respect to the wedges opposite to the direction C, from the back wall **53** toward the apex **55** of the wedges **50A-B**, or in other words, to resist sliding of the sheet **20** down the slope of the ramp surface **52**. In one embodiment, the directional stitching material **45** sliding upon the directional glide material **49** along the axis A of the material **45** and in the direction D of the material **49** provides a resistance to sliding that is at least  $3\times$  greater (e.g.,  $3.5\times$  in one embodiment) than the resistance to sliding along the axis A and in the direction C. In another embodiment, the directional stitching material **45** sliding upon the directional glide material **49** along the axis A of the material **45** and in the direction D of the material **49** provides a resistance to sliding that is at least  $2\times$  greater, or at least  $2.5\times$  greater, than the resistance to sliding along the axis A and in the direction C. Additionally, in one embodiment, the directional stitching material **45** sliding upon the directional glide material **49** along the axis B of the material **45** (perpendicular to the directions C and D of the material **49**) provides a resistance to sliding that is at least  $3.5\times$  greater (e.g.,  $4.1\times$  in one embodiment) than the resistance to sliding along the axis A and in the direction C. In another embodiment, the directional stitching material **45** sliding upon the directional glide material **49** along the axis B of the material **45** (perpendicular to the directions C and D of the material **49**) provides a resistance to sliding that is at least  $2\times$  greater, at least  $2.5\times$  greater, or at least  $3\times$  greater, than the resistance to sliding along the axis A and in the direction C.

(46) The combination of these engagements between the engagement members **61**, **62**, **64** creates a selective gliding assembly **60** with a “one-way” gliding arrangement between the sheet **20** and the wedges **50A-B**, where the sheet **20** can only freely move in the direction C toward the back walls **53** of the wedges **50A-B**, which allows the sheet **20** and the patient **70** to be pulled up onto the ramp surfaces **52** of the wedges **50A-B** without resistance, as described herein. The engagement member **64** of the directional glide material **49** on the base wall **51** of the wedge **50A** also resists sliding of the wedge **50A** away from the apex **55**, or in other words, resists sliding of the wedge **50A** out from underneath the sheet **20**. In one embodiment, the directional glide material **49** sliding against a typical bed sheet material in the direction D provides a resistance to sliding that is at least  $2.5\times$  greater (e.g.,  $2.9\times$  in one embodiment) than the resistance to sliding in the direction C.

Additionally, in one embodiment, the directional glide material **49** sliding against a typical bed sheet material perpendicular to the directions C and D (i.e. toward the foot **17** of the bed **12**) also provides a resistance to sliding that is at least  $2.5\times$  greater (e.g.,  $2.5\times$  in one embodiment) than the resistance to sliding in the direction C. The base walls **51** of the wedges **50A-B** may also include a material or feature to offer some resistance to sliding of the wedges **50A-B** along the axis B in one embodiment, and particularly, in the direction from the top edge **23** to the bottom edge **23** of the sheet **20**, or in other words, from the head **13** to the foot **17** of the bed **12**. For example, a directional stitching material **45** or another directionally-oriented material may be used for this purpose. The resistance to sliding provided by such material may be less than the resistance of the selective gliding assemblies **60** between the sheet **20** and the ramp surfaces **52** of the wedges **50A-B**, such that the sheet **20** will not be encouraged to slide relative to the wedges **50A-B**, and the sheet **20**, the pad **40**, the wedges **50A-B**, and the patient **70** may move together without slipping

relative to one another.

(47) As described herein, the selective gliding assemblies **60** can resist movement in one or more directions and allow free movement in one or more different directions, which may be transverse or opposed to each other. It is understood that the “resistance” to sliding may be expressed using a difference in pull force necessary to create sliding movement between the same pieces of material in different directions. For example, if a selective gliding assembly is considered to “resist” sliding in one direction and “allow” sliding in another direction, this may be determined by having a relatively greater pull force necessary to create sliding movement between two engaging materials in the former direction and a relatively smaller pull force necessary to create sliding movement between the same two materials in the latter direction. The difference in resistance may be expressed quantitatively as well, such as described elsewhere herein. In one embodiment, a selective gliding assembly **60** may resist movement in one direction and may allow movement in another direction that is opposed (i.e., angled 180° to) the first direction. In another embodiment, a selective gliding assembly **60** may resist movement in one direction and may allow movement in another direction angled 90° to the first direction. In a further embodiment, a selective gliding assembly **60** may allow movement in one direction and may resist movement in at least two other directions angled 90° and 180° to the first direction. Still further types of directional gliding assemblies **60** may be constructed using materials as described herein and/or additional materials with directional properties.

(48) In other embodiments, the apparatus **10** may include a different type of supporting device other than the wedges **50A-B** illustrated in FIGS. **1-8**, such as a different type or configuration of wedge or a different type of supporting device. For example, the wedges **50A-B** may be joined together to form a single wedge in one embodiment, which may include a gap at the sacral area. As another example, the apparatus **10** may include a supporting device in the form of a pillow or cushion. It is understood that any supporting device for turning patients **70** that may be included with the apparatus **10** may include any of the features of the wedges **50A-B** described herein, including the engagement members **62**, **64** for forming selective glide assemblies **60**.

(49) The apparatus **10** may further include a support **80** configured to be placed adjacent the sacral area of the patient **70**, such as the back of the upper thighs of the patient **70**, below the patient's buttocks. The support **80** may be connected to one of the wedges **50A-B**. In the embodiment illustrated in FIGS. **1-8**, one of the wedges **50B** has the support **80** connected proximate the apex **55** and extending outwardly from the apex **55**. The support **80** in this embodiment is a pad or pillow that is filled with a fiber fill material, and is divided into three chambers **81**, which are formed by stitched boundaries. In one embodiment, each chamber **81** may be about 9.5"×6" in size and may contain approximately 48 g of fiber fill material. In other embodiments, the support **80** may have a different number of chambers **81**, or may include only a single chamber. The support **80** may use additional or alternate filling in another embodiment as well, including foam materials, bladders to hold air or other fluids, etc. Additionally, in the embodiment illustrated in FIGS. **1-8**, the support **80** is connected to the wedge **50B** by a stitched connection **82** at one end. The connection **82** between the support **80** and the wedge **50B** allow the components to be handled and inserted simultaneously, avoid possible positioning conflicts between the components, and assist in ensuring that the support is accurately and consistently positioned. In other embodiments, the support **80** may be connected in a different configuration. For example, as shown in FIG. **9**, the support **80** may be connected to the wedge **50B** by a hook-and-loop (e.g. Velcro) connection **86**. As another example, the support **80** may not be connected to the wedge **50B** at all. The support **80** may be shaped and/or connected differently in further embodiments.

(50) The support **80** may also include an engagement member **66** forming part of a selective gliding assembly **60**, such as a directional stitching material **45**, a directional gliding material, or other directionally-oriented material. In the embodiment illustrated in FIGS. **1-8**, the support **80** has an engagement member **66** on the top surface **83**, in the form of a directional stitching material **45**

(which may also be referred to as a “support engagement member”). The directional stitching material **45** may generally cover at least a portion of the top surface **83** of the support **80**, and in the embodiment illustrated in FIGS. **1-8**, the directional stitching material **45** covers all or substantially all of the top surface **83** of the support **80**. In this embodiment, the axis B (along which gliding is resisted) of the directional stitching material **45** is oriented to extend across the elongation direction of the support **80** and parallel to the apex edge **55** of the wedge **50B**, and the axis A (along which gliding is allowed) is oriented to extend parallel to the elongation direction of the support **80** and away from the apex **55** of the wedge **50B**. The engagement member **66** on the top surface **83** of the support **80** is configured to engage the engagement member **61** on the bottom surface **22** of the sheet **20** in order to form a selective gliding assembly **60**. In this arrangement, the selective gliding assembly **60** formed by the engagement members **61**, **66** resists gliding of the sheet **20** relative to the support **80** along the axis B extending between the top and bottom edges **23** of the sheet **20** and between the head **13** and the foot **17** of the bed. In particular, this arrangement resists sliding of the sheet **20** downward toward the foot **17** of the bed **12** separately from the support **80**, which can both retain the support **80** in proper position relative to the patient **70** and resist sliding of the patient **70** downward on the bed **12**. This arrangement is illustrated schematically in FIG. **12**. The bottom surface **84** of the support **80** is at least partially formed or covered by a low friction material **85**, which may be the same low friction material **25** as used in the sheet **20**. This low friction material **85** facilitates sliding the support **80** beneath the patient **70**, as described herein, and also facilitates the support **80** and the wedge **50B** with the sheet **20**, such that the sheet **20** and/or the patient **70** do not move relative to the support **80** and the wedge **50B**. In another embodiment, at least a portion of the bottom surface **84** may include such an engagement member to resist sliding on the bed **12**.

(51) All or some of the components of the system **10** can be provided in a kit, which may be in a pre-packaged arrangement, as described in U.S. Patent Application Publication No. 2012/0186012, published Jul. 26, 2012, which is incorporated by reference herein in its entirety and made part hereof. For example, the sheet **20** and the pad **40** may be provided in a pre-folded arrangement or assembly, with the pad **40** positioned in confronting relation with the top surface **21** of the sheet **20**, in approximately the same position that they would be positioned in use, and the sheet **20** and pad **40** can be pre-folded to form a pre-folded assembly **65**, as illustrated in FIG. **10**. The pre-folded assembly **65** can be unfolded when placed beneath a patient, as shown in FIG. **10**. It is understood that different folding patterns can be used. The pre-folded sheet **20** and pad **40** can then be unfolded together on the bed **12**, as described below, in order to facilitate use of the system **10**. Additionally, the sheet **20** and the pad **40** can be packaged together, by wrapping with a packaging material to form a package, and may be placed in the pre-folded assembly **65** before packaging. The one or more wedges **50** may also be included in the package, in one embodiment. Other packaging arrangements may be used in other embodiments.

(52) Example embodiments of methods for utilizing the system **10** are illustrated in FIGS. **10-11**. FIGS. **10a-d** illustrate an example embodiment of a method for placing the sheet **20** and pad **40** under a patient **70**, which utilizes a pre-folded assembly **65** of the sheet **20** and pad **40**. The method is used with a patient **70** lying on a bed **12** as described above, and begins with the sheet **20** and pad **40** unfolded length-wise in a partially-folded configuration. As shown in FIG. **10a**, the patient **70** is rolled to one side, and the pre-folded assembly **65** is placed proximate the patient **70**, so that a first side **71** of the assembly **65** is ready for unfolding, and the second side **73** is bunched under and against the back of the patient **70**. The sheet **20** and pad **40** should be properly positioned at this time, to avoid the necessity of properly positioning the sheet **20** and pad **40** after the patient **70** is lying on top of them. In this embodiment, the sheet **20** is properly positioned when the top strip **29B** is positioned near the head **13** of the bed **12** and approximately aligned with the shoulders of the patient **70**, with the patient **70** positioned with his/her sacral area at the joint **72** where the bed **12** inclines (see FIG. **10d**). The pad **40** is properly positioned in the pre-folded assembly **65**, but

may require positioning relative to the sheet **20** if the pad **40** is instead provided separately.

(53) After positioning the second side **73** of the sheet **20** and pad **40** under or proximate the patient's back, the first side **71** of the sheet **20** and pad **40** assembly **65** (on the left in FIGS. **10a-b**) is unfolded onto the bed **12**. This creates a folded portion that is bunched under the patient **70** and an unfolded portion that is unfolded on the bed **12**. The patient **70** is then rolled in the opposite direction, so that the second side **73** of the sheet **20** and pad **40** can be unfolded on the bed **12**, as shown in FIG. **10b**. The sheet **20** and pad **40** may be provided in a folded arrangement where the first and second sides **71**, **73** of the sheet **20** and pad **40** can be unfolded away from the center. The patient **70** can then be rolled onto his/her back on top of the sheet **20** and pad **40**. The patient **70** may be moved slightly to ensure proper positioning after unfolding the assembly **65**, which can be accomplished by sliding the sheet **20** using the handles **28**, **48**. The bed **12** can then be inclined if desired. The method illustrated in FIGS. **10a-d** typically requires two or more caregivers for performance, but is less physically stressful and time consuming for the caregivers than existing methods. The pad **40** can be removed and replaced by rolling the patient **70** and unfolding the pad **40** using a method similar to the method described herein with respect to FIGS. **10a-d**.

(54) FIGS. **11a-d** illustrate an example embodiment of a method for placing the patient in an angled resting position by placing two wedges **50A-B** and the support **80** under the patient **70**. The method is used with a patient **70** lying on a bed **12** as described above, having a bed sheet **15** (e.g., a fitted sheet) on the supporting surface **16**, with the sheet **20** and pad **40** of the system **10** lying on top of the bed sheet **15** and the patient **70** lying on the pad **40**. In this embodiment, the wedges **50A-B** and the support **80** are positioned on top of the bed sheet **15**, such that the bed sheet **15** contacts the base wall **51** of the wedge **50A-B** and the bottom surface **84** of the support **80**, and the ramp surface **52** of the wedge **50A-B** and the top surface **83** of the support **80** contact the sheet **20**. It is understood that no bed sheet **15** or other cover for the mattress **18** may be present in some embodiments, in which case the wedges **50** can be placed directly on the mattress **18**. As shown in FIG. **11a-b**, the edge of the sheet **20** is lifted, and the wedges **50A-B** and the support **80** are inserted from the side of the bed **12** under the sheet **20** toward the patient **70**. The support **80** may be inserted by the user **74** grasping the free end (opposite the connection **82**), lifting the sheet **20** beneath the patient's thighs, and pushing the support into position, as shown in FIG. **11b**. At this point, at least the apex **55** of each wedge **50A-B** may be pushed toward, next to, or at least partially under the patient **70**. The selective gliding assemblies **60** between the wedges **50A-B** and the bottom surface **22** of the sheet **20** do not resist such insertion and allow free gliding of the wedge toward the patient and away from the side edge of the bed. This insertion technique may position the patient to the desired angle with no further movement of the patient **70** necessary. In one embodiment, the wedges **50A-B** should be aligned so that the wedges are spaced apart with one wedge **50A** positioned at the upper body of the patient **70** and the other wedge **50B** positioned at the lower body of the patient **70**, with the patient's sacral area positioned in the space between the wedges **50A-B**. It has been shown that positioning the wedges **50A-B** in this arrangement can result in lower pressure in the sacral area, which can reduce the occurrence of pressure ulcers in the patient **70**. The wedges **50A-B** may be positioned approximately 10 cm apart in one embodiment, or another suitable distance to provide space to float the sacrum, or in other words, to have minimal force on the sacrum. The support **80** is also pushed beneath the upper legs/thighs of the patient **70**, downward of the sacral area, and the selective gliding assembly **60** between the support **80** and the bottom surface **22** of the sheet **20** does not resist such insertion.

(55) Once the wedges **50A-B** and the support **80** have been inserted, the patient **70** may be in the proper angled position. If the patient **70** requires further turning to reach the desired angled position, the user **74** (such as a caregiver) can pull the patient **70** toward the wedges **50A-B** and toward the user **74**, such as by gripping the handles **28** on the sheet **20**, as shown in FIG. **11c**. This moves the proximate edge of the sheet **20** toward the back walls **53** of the wedges **50A-B** and toward the user **74**, and slides the patient **70** and at least a portion of the sheet **20** up the ramp

surface **52**, such that the ramp surface **52** partially supports the patient **70** to cause the patient **70** to lie in an angled position. During this pulling motion, the selective gliding assemblies **60** between the ramp surfaces **52** of the wedges **50A-B** and the sheet **20** do not resist movement of the sheet **20**, the engagement member **64** on the base wall **51** of the wedge **50A** resists movement of the wedge **50A** toward the user **74** (i.e., away from the patient **70** and toward the side edge of the bed **12**), and the high friction surface **24** of the sheet **20** resists movement of the pad **40** and/or the patient **70** with respect to the sheet **20**.

(56) When the patient **70** is to be returned to lying on his/her back, the wedges **50A-B** and the support **80** can be removed from under the patient **70**. The sheet **20** may be pulled in the opposite direction in order to facilitate removal of the wedges **50A-B** and support **80** and/or position the patient **70** closer to the center of the bed **12**. The patient **70** can be turned in the opposite direction by inserting the wedges **50A-B** and the support **80** under the opposite side of the bed sheet **15**, from the opposite side of the bed **12**, and pulling the sheet **20** in the opposite direction to move the patient **70** up the ramp surfaces **52** of the wedges **50A-B** and the support **80**, in the same manner described above.

(57) Once the wedges **50A-B** and the support **80** are positioned beneath the patient **70** and the sheet **70**, the various selective gliding assemblies **60** resist undesirable movement of the patient **70** and the sheet **20**. For example, the selective gliding assemblies **60** between the ramp surfaces **52** of the wedges **50A-B** and the bottom surface **22** of the sheet **20** resist slipping of the sheet **20** down the ramp surfaces **52**, and also resist slipping of the sheet **20** downward toward the foot **17** of the bed **12**, and further resist slipping of the wedges **50A-B** rearward away from the patient **70** and toward the side edge of the bed **12**. As another example, the selective gliding assembly **60** on the base wall **51** of the wedge **50A** resists slipping of the wedge **50A** rearward away from the patient **70** and toward the side edge of the bed **12**. As a further example, the selective gliding assembly **60** between the support **80** and the sheet **20** resists slipping of the sheet **20** downward (i.e., toward the foot **17** of the bed **12**) with respect to the support **80**. Still further, the support **80** may also provide support to the patient **70** to prevent slipping toward the foot **17** of the bed **12**. These features in combination provide increased positional stability to the patient **70** as compared to existing turning and/or positioning systems, thereby reducing the frequency and degree of necessary repositioning. The patient **70**, the pad **40**, the sheet **20**, and the wedges **50A-B** tend to move “together” on the bed **12** in this configuration, so that these components are not unacceptably shifted in position relative to each other. This, in turn, assists in maintaining the patient **70** in optimal position for greater periods of time and reduces strain and workload for caregivers. To the extent that repositioning is necessary, the handles **28, 48** on the sheet **20** are configured to assist with such repositioning in a manner that reduces strain on caregivers.

(58) As described above, in some embodiments, the wedges **50A-B** may have an angle of up to approximately 45°, or from approximately 15-35°, or approximately 30°. Thus, when these embodiments of wedges **50A-B** are used in connection with the method as shown in FIG. **11a-d**, the patient **70** need not be rotated or angled more than 45°, 35°, or 30°, depending on the wedge **50A-B** configuration. The degree of rotation can be determined by the rotation or angle from the horizontal (supine) position of a line extending through the shoulders of the patient **70**. Existing methods of turning and positioning patients to relieve sacral pressure often require rolling a patient to 90° or more to insert pillows or other supporting devices underneath. Rolling patients to these great angles can cause stress and destabilize some patients, particularly in patients with critical illnesses or injuries, and some critical patients cannot be rolled to such great angles, making turning of the patient difficult. Accordingly, the system **10** and method described above can have a positive effect on patient health and comfort. Additionally, the angled nature of the wedges **50A-B** can allow for more accurate positioning of the patient **70** to a given resting angle, as compared to existing, imprecise techniques such as using pillows for support. Further, the selective gliding assemblies **60** resist undesired slipping with respect to the wedges **50A-B**, which aids in

maintaining the same turning angle.

(59) The use of the system **10** and methods described above can decrease the number of pressure ulcers in patients significantly. The system **10** reduces pressure ulcers in a variety of manners, including reducing pressure on sensitive areas, reducing shearing and friction on the patient's skin, and managing heat and moisture at the patient's skin. The system **10** can reduce pressure on the patient's skin by facilitating frequent turning of the patient and providing consistent support for accurate resting angles for the patient upon turning. The system **10** can reduce friction and shearing on the patient's skin by resisting sliding of the patient along the bed **12**, including resisting sliding of the patient downward after the head **13** of the bed **12** is inclined, as well as by permitting the patient to be moved by sliding the sheet **20** against the bed **12** instead of sliding the patient. The system **10** can provide effective heat and moisture management for the patient by the use of the absorbent body pad. The breathable properties of the sheet **20** and pad **40** are particularly beneficial when used in conjunction with an LAL bed system. Increased breathability also permits the system **10** to be placed underneath the patient **70** for extended periods of time. When used properly, pressure ulcers can be further reduced or eliminated.

(60) The use of the system **10** and methods described above can also have beneficial effects for nurses or other caregivers who turn and position patients. Such caregivers frequently report injuries to the hands, wrists, shoulders, back, and other areas that are incurred due to the weight of patients they are moving. Use of the system **10**, including the sheet **20** and the wedges **50A-B**, can reduce the strain on caregivers when turning and positioning patients. For example, existing methods for turning and positioning a patient **70**, such as methods including the use of a folded-up bed sheet for moving the patient **70**, typically utilize lifting and rolling to move the patient **70**, rather than sliding. Protocols for these existing techniques encourage lifting to move the patient and actively discourage sliding the patient, as sliding the patient using existing systems and apparatuses can cause friction and shearing on the patient's skin. The ease of motion and reduction in shearing and friction forces on the patient **70** provided by the system **10** allows sliding of the patient **70**, which greatly reduces stress and fatigue on caregivers.

(61) As another example, the use of the pre-folded assembly **65** of the sheet **20** and pad **40** facilitates installation of the system **10**, such as in FIGS. **10a-d**, providing an advantage for caregivers. The interaction between the sheet **20** and pad **40**, including the high friction material **24** of the sheet **20**, as well as the simultaneous unfolding of the sheet **20** and pad **40**, also help avoid wrinkles in the sheet **20** and/or the pad **40**, which can cause pressure points that lead to pressure ulcers.

(62) As another example, the use of the apparatus **10** and method as described above requires less effort for complete turning of the patient **70**, as compared to other apparatuses and methods currently in existence. The act of pulling and sliding the sheet **20** and patient **70** toward the caregiver **74** to turn the patient **70** to an angled position, as shown in FIG. **11c**, creates an ergonomically favorable position for movement, which does not put excessive stress on the caregiver **74**. In particular, the caregiver **74** does not need to lift the patient **70** at all, and may turn the patient **70** simply by inserting the wedges **50A-B** underneath the patient **70** and (if necessary) pulling on the handles **28** to allow the mechanical advantage of the ramp surface **52** to turn the patient **70**. Additionally, it allows the patient **70** to be turned between the angled and non-angled positions (e.g. 30°-0°-30°) by only a single caregiver. Prior methods often require two or more caregivers. Still other benefits and advantages over existing technology are provided by the system **10** and methods described herein, and those skilled in the art will recognize such benefits and advantages.

(63) Several alternative embodiments and examples have been described and illustrated herein. A person of ordinary skill in the art would appreciate the features of the individual embodiments, and the possible combinations and variations of the components. A person of ordinary skill in the art would further appreciate that any of the embodiments could be provided in any combination with

the other embodiments disclosed herein. It is understood that the invention may be embodied in other specific forms without departing from the spirit or central characteristics thereof. The present examples and embodiments, therefore, are to be considered in all respects as illustrative and not restrictive, and the invention is not to be limited to the details given herein. The terms “first,” “second,” “top,” “bottom,” etc., as used herein, are intended for illustrative purposes only and do not limit the embodiments in any way. Additionally, the term “plurality,” as used herein, indicates any number greater than one, either disjunctively or conjunctively, as necessary, up to an infinite number. Further, “providing” an article or apparatus, as used herein, refers broadly to making the article available or accessible for future actions to be performed on the article, and does not connote that the party providing the article has manufactured, produced, or supplied the article or that the party providing the article has ownership or control of the article. Accordingly, while specific embodiments have been illustrated and described, numerous modifications come to mind without significantly departing from the spirit of the invention.

## Claims

1. A system for use with a bed having a frame and a supporting surface supported by the frame, the system comprising: a sheet having a bottom surface configured to be placed above the supporting surface of the bed and a top surface opposite the bottom surface; and a wedge comprising a wedge body having a base wall, a ramp surface, and a back wall, the ramp surface joined to the base wall to form a first apex, the ramp surface joined to the back wall to form a second apex, wherein the base wall has a base engagement member; wherein the wedge is configured to be positioned under the sheet such that the base wall confronts the supporting surface of the bed and the ramp surface confronts the bottom surface of the sheet, wherein the base engagement member is configured to engage a surface of the bed to form a selective gliding assembly that resists movement of the wedge with respect to the bed in a first direction extending from the back wall toward the first apex, such that a first pull force necessary to create sliding movement of the wedge with respect to the surface of the bed in the first direction is greater compared to a second pull force necessary to create sliding movement of the wedge with respect to the surface of the bed in any direction other than the first direction, and wherein the base engagement member is configured as a patch, the patch covering only a first portion of the base wall such that edges of the base engagement member are spaced from edges of the base wall to allow a second portion of the base wall to be exposed, the patch located closer to the first apex in a second direction than to the second apex in a third direction, each of the second direction and the third direction being along the ramp surface.
2. The system of claim 1, wherein the base engagement member comprises a directional glide material.
3. The system of claim 1, further comprising a support connected to the wedge and extending from the first apex and configured to be positioned under the sheet in an upper thigh area of a patient, such that a bottom surface of the support confronts the supporting surface of the bed and a top surface of the support confronts the bottom surface of the sheet, the support divided into a plurality of fillable chambers.
4. The system of claim 1, wherein the sheet comprises a first piece of a first material having a first coefficient of friction and a second material connected to the first piece, the second material having a second coefficient of friction, wherein the second material forms at least a portion of the top surface, and wherein the second coefficient of friction is higher than the first coefficient of friction, such that the top surface provides greater slipping resistance in at least one direction than the bottom surface.
5. The system of claim 4, wherein the second material comprises the first material and a coating applied to the first material.
6. The system of claim 5, wherein the coating comprises at least one of a hot melt adhesive or a

plastic.

7. The system of claim 4, wherein the first material comprises at least one of polyester or nylon.

8. The system of claim 4, wherein the second material comprises a knitted material.

9. The system of claim 4, wherein the second coefficient of friction is between about 8 and about 10 times higher than the first coefficient of friction.

10. The system of claim 4, wherein the second coefficient of friction is at least 5 times higher than the first coefficient of friction.

11. The system of claim 1, wherein: the ramp surface of the wedge has a first ramp engagement member; the system further comprises a second wedge comprising a second wedge body having a second base wall, a second ramp surface, and a second back wall, the second ramp surface joined to the second base wall to form a third apex, wherein the second ramp surface has a second ramp engagement member; the second wedge is configured to be positioned under the sheet such that the second base wall confronts the supporting surface of the bed and the second ramp surface confronts the bottom surface of the sheet; and the second ramp engagement member is configured to engage a sheet engagement member disposed on the bottom surface of the sheet to form a second selective gliding assembly that resists movement of the sheet with respect to the second ramp surface in a fourth direction, such that a third pull force necessary to create sliding movement of the sheet with respect to the second ramp surface in the fourth direction is greater compared to a fourth pull force necessary to create sliding movement of the sheet with respect to the second ramp surface in a fifth direction.

12. The system of claim 11, wherein the sheet engagement member comprises a first piece of directional stitching material configured to engage the first ramp engagement member of the wedge and a second piece of directional stitching material configured to engage the second ramp engagement member of the second wedge.

13. A system for use with a bed having a frame and a supporting surface supported by the frame, the system comprising: a sheet having a bottom surface configured to be placed above the supporting surface of the bed and a top surface opposite the bottom surface; and a wedge comprising a wedge body having a base wall and a ramp surface, the ramp surface joined to the base wall to form an apex, wherein the base wall has a base engagement member and the ramp surface has a ramp engagement member; wherein the wedge is configured to be positioned under the sheet such that the base engagement member is configured to engage a surface of the bed to form a first selective gliding assembly and the ramp engagement member is configured to engage a sheet engagement member disposed on the bottom surface of the sheet to form a second selective gliding assembly; wherein the base engagement member is configured as a first patch, the first patch covering only a first portion of the base wall such that edges of the base engagement member are spaced from edges of the base wall to allow a second portion of the base wall to be exposed; and wherein the ramp engagement member is configured as a second patch, the second patch covering only a first portion of the ramp surface such that edges of the ramp engagement member are spaced from edges of the ramp surface to allow a second portion of the ramp surface to be exposed.

14. The system of claim 13, further comprising a support connected to the wedge and extending from the apex, the support being configured as a pad or pillow.

15. The system of claim 14, wherein the support comprises at least one fillable chamber.

16. The system of claim 14, wherein the support is connected to the wedge via a hook and loop connection.

17. The system of claim 13, wherein the first selective gliding assembly resists movement of the wedge with respect to the bed in a first direction and allows movement in a second direction.

18. The system of claim 17, wherein the second selective gliding assembly resists movement of the wedge with respect to the bed in a third direction and allows movement in a fourth direction.

19. The system of claim 18, wherein the second direction is transverse to the first direction and the

fourth direction is transverse to the third direction.

20. The system of claim 13, wherein the second selective gliding assembly comprises a directional stitching material positioned on the bottom surface of the sheet and the ramp surface of the wedge and a directional glide material also positioned on the ramp surface of the wedge.
