VIRTUAL QUEUE SYSTEM AND METHOD

Abstract

A system in accordance with present embodiments includes a plurality of wearable devices and a virtual queue control system configured to maintain respective virtual queues for respective attractions and in communication with the plurality of virtual queuing attraction stations. The virtual queue control system is configured to receive communications from the plurality of virtual queuing stations and add guests to the respective virtual queues based on the communications.

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS [0001] The present application is a continuation of U.S. patent application Ser. No. 18/140,397, entitled “Virtual Queue System and Method,” filed Apr. 27, 2023, which is a continuation of U.S. patent application Ser. No. 17/505,887, entitled “Virtual Queue System and Method,” filed on Oct. 20, 2021, which issued on Jun. 6, 2023 as U.S. Pat. No. 11,670,126, which is a continuation of U.S. patent application Ser. No. 16/806,557, entitled “Virtual Queue System and Method,” filed on Mar. 2, 2020, which issued on Nov. 23, 2021 as U.S. Pat. No. 11,182,998, which is a continuation of U.S. patent application Ser. No. 16/210,982, entitled “Virtual Queue System and Method,” filed on Dec. 5, 2018, which issued on Mar. 3, 2020 as U.S. Pat. No. 10,580,244, which is a continuation of U.S. patent application Ser. No. 15/460,010, entitled “Virtual Queue System and Method,” filed on Mar. 15, 2017, which issued on Dec. 11, 2018 as U.S. Pat. No. 10,152,840, and which claims the benefit of U.S. Provisional Application No. 62/309,306, entitled “Virtual Queue System and Method” and filed Mar. 16, 2016, the disclosures of which are incorporated herein by reference for all purposes.

BACKGROUND

[0002] The present disclosure relates generally to the field of amusement parks. More specifically, embodiments of the present disclosure relate to methods and equipment utilized to manage amusement park experiences, including queuing for attractions.

[0003] Since the early twentieth century, amusement parks have substantially grown in popularity. In order to address this increasing demand, amusement parks have been expanding by adding attractions and space. The addition of attractions (e.g., rides, restaurants, shops, and shows) generally provides an amusement park with additional capacity to handle a larger number of guests. However, the additional attractions also typically provide potential guests with an incentive to visit the amusement park. Thus, while a particular amusement park may add additional capacity, the additional capacity does not always result in an increased ability for guests to participate in park entertainment (e.g., shopping, viewing shows, riding rides) or reduced wait times for attractions. This is because there is often a corresponding increase in attendance. Further, due to operating efficiencies, it is often desirable to limit the availability of attractions during low attendance times. Thus, queuing for attractions, which may limit participation in park activities, is a perennial issue for amusement parks.

[0004] While guests have demanded bigger, better, and more elaborate attractions, they also require and expect a positive overall experience. Providing a positive overall experience for amusement park guests entails addressing certain issues related to queuing for attractions. Indeed, it is now recognized that park guests can be deterred from returning to a particular amusement park due to negative experiences with queue waiting times. Further, guests may be prevented from accessing

amusement park businesses (e.g., shops) due to time spent waiting in queues. Indeed, in the past, guests have been forced to wait hours in line to experience some of the more popular attractions at an amusement park. Additionally, it is now recognized that park capacity does not always equal guest utilization of that capacity due to individual guest preferences for certain attractions over others. Accordingly, it is now recognized that it is desirable to improve amusement park queuing systems and methods.

SUMMARY

[0005] Certain embodiments commensurate in scope with the originally claimed subject matter are summarized below. These embodiments are not intended to limit the scope of the disclosure, but rather these embodiments are intended only to provide a brief summary of certain disclosed embodiments. Indeed, the present disclosure may encompass a variety of forms that may be similar to or different from the embodiments set forth below.

[0006] In accordance with one embodiment, a virtual queue system is provided that includes at least one wearable device comprising: a near field communicator; a medium range communicator; a long range communicator; and a display. The virtual queue system also includes a control system storing instructions that, when executed, cause the control system to: assign a user identification associated with the at least one wearable device to a position within a virtual queue for an attraction based on communication with the near field communicator; and communicate to one or both of the medium range communicator and the long range communicator the position assigned to the user identification within the virtual queue. The virtual queue system also includes an attraction station located proximate the attraction and comprising: a station near field communicator configured to validate access to the attraction based on confirmation of the user identification, received from the wearable device via the near field communicator, being associated with the position in the virtual queue corresponding to an entry position of the virtual queue for the attraction; and wherein one or both of the at least one wearable device or the attraction station is configured to generate a notification that the wearable device is associated with a valid access to the attraction.

[0007] In accordance with another embodiment, a virtual queue system is provided that includes at least one wearable device comprising: a near field communicator; a medium range communicator; a long range communicator; and a display. The virtual queue system also includes a control system storing instructions that, when executed, cause the control system to: assign a user identification associated with the at least one wearable device to a position within a virtual queue for an attraction based on communication with the near field communicator; and communicate to one or both of the medium range communicator and the long range communicator, the position assigned to the user identification within the virtual queue to cause the wearable device to display a countdown on the display when the position is within a predetermined time from valid entry to the attraction; and an attraction station located proximate the attraction and comprising: a station near field communicator configured to validate access to the attraction based on confirmation of the user identification, received from the wearable device via the near field communicator, being associated with the position in the virtual queue corresponding to an entry position of the virtual queue for the attraction.

[0008] In accordance with another embodiment, a virtual queue system is provided that includes at least one wearable device comprising: a near field communicator; a medium range communicator; a long range communicator; and a display. Also included is a virtual queue station comprising a near field communicator that receives a user identification from the near field communicator of the at least one wearable device; and a virtual queue control system configured to receive the user identification, wherein receiving the user identification causes the virtual queue control system to execute instructions to: : assign the user identification associated with the at least one wearable device to a position within a virtual queue for an attraction based on communication with the near field communicator; and communicate to one or both of the medium range communicator and the long range communicator the position within the virtual queue assigned to the user identification

and positions of other wearable devices associated with the user identification to cause the wearable device to display the position and the wearable devices associated with the user identification.

[0009] In accordance with another embodiment, a virtual queue system is provided that includes at least one wearable device comprising: a near field communicator; a medium range communicator; a long range communicator; and a display. Also included is a control system storing instructions that, when executed, cause the control system to: assign a user identification associated with the at least one wearable device to a position within a virtual queue for an attraction based on communication with the near field communicator; and communicate to one or both of the medium range communicator and the long range communicator the position assigned to the user identification within the virtual queue to the wearable device associated with the user identification; an attraction station located proximate the attraction and comprising: a station near field communicator configured to validate access to the attraction based on confirmation of the user identification, received from the wearable device via the near field communicator, being associated with the position in the virtual queue corresponding to an entry position of the virtual queue for the attraction, wherein one or both of the at least one wearable device or the attraction station is configured to generate a notification that the wearable device is associated with a valid access to the attraction; and an effects station configured to trigger a pre-programmed effect in response to receiving a signal from the near field communicator.

Description

DRAWINGS

[0010] These and other features, aspects, and advantages of the present disclosure will become better understood when the following detailed description is read with reference to the accompanying drawings in which like characters represent like parts throughout the drawings, wherein:

[0011] FIG. 1 is a schematic view of a theme park including a virtual queue system in accordance with present techniques;

[0012] FIG. 2 is a block diagram of an active wearable in accordance with present techniques; and

[0013] FIG. 3 is a block diagram of a virtual queue system in accordance with present techniques.

DETAILED DESCRIPTION

[0014] Presently disclosed embodiments facilitate virtual queuing within a theme park. A virtual queue control system as provided herein manages queuing for various attractions with the theme park to minimize or eliminate guest time spent waiting in a physical queue. In certain embodiments, a given attraction has a single virtual queue that is dynamically managed by the control system to add or remove guests, update positions in the queue, and send messages to the guests related to their queue positions. The system receives various inputs from the attractions and/or guests that are used to dynamically manage the various queues. In certain embodiments, queuing is mediated via guest devices such as active wearables (e.g., bracelets, wearable tags, necklaces or badges, etc.) that are carried by or associated with the guests and that interact with various kiosks or check-in points to permit guest to enter attraction queues. In this manner, park guests may enjoy the park without carrying paper tickets, identification, or other credentials. For example, guests at a water park may not wish to manage paper tickets that can get wet. Further, because guests wearing bathing suits have limited ability to carry identification items or handheld devices, active wearables that are compatible with water activities (e.g., waterproof) may be a more convenient way to manage queue information than a mobile device.

[0015] The present disclosure relates to a virtual queue system for a theme park (e.g., water park), wherein the virtual queue (VQ) system may include an active wearable device such as a wearable

virtual queue wristband (which may be customizable with modules and decorative features). In addition, the virtual queue system may be operated in conjunction with software for allocation of or entry to a virtual queue via a “Tap-Point” module and software for ride validation via a “Tap-Point” module and other control system components. In accordance with present embodiments, interconnection (protocols and application program interface (API)) of the virtual queue system and a guest profile system may be customizable to facilitate changing purposes.

[0016] FIG. 1 is a schematic representation of a system **100** for facilitating queuing in accordance with present embodiments. The system **100** includes a computer system **102**, monitoring sensors **104**, a wireless communication system **106**, system displays **108**, active wearables **110** (e.g., a bracelet including accessible data and communication features) and other components that coordinate in accordance with present embodiments, as will be described in detail below. Specifically, it should be noted that present embodiments facilitate virtual queuing such that amusement park guests **120** can obtain a position within a virtual queue and subsequently enter a physical queue or standby loading group **122** of limited length. Present embodiments may function to limit time spent by guests **120** in physically waiting **122** and encourage participation in other areas of an amusement park, such as dining, shopping, and other entertainment venues (e.g., rides, shows). Accordingly, in one embodiment, the attraction queue is mediated entirely via the virtual queue and without physical queues.

[0017] When guests **120** arrive at a ticketing location **124** (e.g., hotel front desk, kiosk, guest service counter, park gate), the guests **120** may be provided with entry credentials (e.g., tickets or active wearables **110**) among other items, such as a park map, virtual queuing instructions, and amenities instructions. Informational media (e.g., audio, video) and instructional signage may be present at all such ticketing locations **124**. In some instances, guests **120** may have obtained entry credentials prior to arrival and may skip acquiring such credentials at the ticketing location **124**.

[0018] Guests may enter and be provided entry into the park or a park area via an entryway **126**. Specifically, as illustrated in FIG. 1, the entryway **126** may exclude a physical turnstile or similar physical traversal counting or control features that can provide an impediment to traversal of the entryway **126** when the entryway **126** is intended to be open. That is, the entryway **126** may be turnstile-less during operation. If guests **120** already have their entry credentials or an identification code or number transferred into an active wearable (“AW”) **110**, the guests **120** may be provided essentially direct access to the park or park area. For example, guests **120** with properly activated AWs **110** may be allowed to walk through the entryway **126** without stopping. The credentials associated with the AW **110** being held or worn by the guests **120** will be detected and provided to a gate monitoring facility **128** that may be monitored by a park employee (e.g., a security service company). For example, this may include providing a photograph of the guest **120** (e.g., a photograph of the guest's face) passing through the entryway **126**. Thus, the photograph may be used for entry privilege confirmation. In other embodiments, other features may be used, such as fingerprints or other identifying aspects (e.g., facial recognition). While certain embodiments of the disclosure are illustrated in conjunction with an AW **110**, it should be understood that the disclosed techniques may be implemented with guest-associated devices that are configured to wirelessly communicate guest information, such as pocket-carried devices, handheld devices, or mobile devices. In particular embodiments, the guest-associated devices are waterproof.

[0019] If guests **120** do not have their AW **110** with them or if their AW **110** is not properly activated, they may insert ticket media **132** into a scanner **134**, which facilitates transfer of information to the gate monitoring facility **128**, which may include any of a number of gate monitoring systems, and informs a park employee that the guest **120** is authorized to enter the park or park area. If authorization is granted in this manner, an AW **110** may be distributed to them and a photograph of the guest's face automatically taken. For example, a photograph may be automatically taken by a camera **136** positioned proximate the entryway **126**. The same camera **136** may be used for monitoring purposes as well. In other embodiments, the picture of guests **120**

acquiring their AW **110** may occur in a different location. Further, in some embodiments, the guests **120** may acquire their AW **110** after progressing through the entryway **126** or prior to progressing through the entryway **126**.

[0020] Wait times may be ascertained by guests by viewing displays provided at numerous locations throughout the park or park area. At the entrance of certain or all attractions, displays **108** provide the wait time for the specific attraction. For example, the water slide **142** includes a display **144** that specifically provides a wait time for that attraction. The information for each display may be provided based on information obtained by tracking AWs **110** or otherwise monitoring park areas (e.g., ride exits and entrances) with monitoring sensors **104**. Further, at the exit of certain or all attractions, a display may be provided to indicate the wait times for all attractions (e.g., all attractions in the park or park area). For example, the exit area of the water slide **142** includes a display **146** that may provide wait times for all of the surrounding attractions (e.g., rides **148**). The display **146** may even provide wait times for non-ride attractions, such as a wait time for a restaurant **150**. The display **146** may be limited to display of wait times for attractions within a particular park area **152** (e.g., a park “village”). Also, within each park area **152**, one or more wait time boards **154** (e.g., centrally located displays **108**) may indicate wait times for all park attractions or attractions within the park area **152**. Further still, before guests **120** place their portable devices (e.g., mobile phones) into lockers **160**, mobile applications may be used via the mobile devices to ascertain wait times.

[0021] In one embodiment, the guest **120** enters the queue by walking to the attraction entry and walking through an entry portal. For example, the guest **120** may walk to the water slide **142** and walk through its attraction station **166**. Once the guest **120** walks through the portal **166**, the guest's AW **110** will notify him/her (e.g., via a tone, vibration, illuminator) of being added to the virtual queue. This may be achieved by detecting the AW **110** with the monitoring sensor **104** at the attraction station **166** and via aspects of the AW **110**, which will be discussed further below. In another embodiment, the guest **120** may enter the virtual queue by walking to a queue entry post **168**, which may indicate the name of the attraction and current wait time, and engaging the post **168** with the AW **110**. This may include tapping the AW **110** against or positioning it near the post **168**. The posts **168** may be located at the exit or entry of each attraction and at a central location within each park area **152** or village. In one embodiment, an individual post **168** may be associated with only one attraction such that engaging with the post **168** automatically enters the guest **120** in the virtual queue of the associated attraction, e.g., the virtual queue is entered without any guest selection between different attractions at the post **168**, and tapping or engaging the post is the selection step for selecting the associated attraction. In particular embodiments, the queue entry post **168** and/or the attraction station **166**, when positioned proximate an attraction, such as at an attraction entrance, may function as an entrance validator for guests already in a virtual queue.

[0022] The queue entry post **168** and the attraction station **166** may have similar functionality to one another for adding guests to a virtual queue. In addition, the attraction station **166**, when positioned proximate the attraction, such as at the ride entry, may also include functionality for communicating if the guest has a valid entry position to the attraction. Validation may include near field communication with the AW **110** to access the user identification associated with the AW **110** when a guest taps in to the attraction station **166**. The user identification is then communicated to a central virtual queue control system remote from the attraction station **166**, which in turn accesses the real-time queue position associated with the user identification AW **110**, performs rules-based filtering, and provides a validation output of a valid or an invalid position in the virtual queue for attraction entry. For example, in one example of rules-based filtering, when a guest position is at the front of the virtual queue (position 1), the guest is validated for admission. In other embodiments, when the guest position is in a front group (e.g., positions 1-10), the guest is validated for admission. In one embodiment, to encourage guests to return to the attraction for entry, all positions in the virtual queue less than a predetermined number (e.g., 10 or 5) are

displayed as position 1 or are displayed on the AW **110** or otherwise indicated as being valid for entry (e.g., tone, vibration, display). In another example, when guests in positions 1-x in the virtual queue are not yet present at the attraction, and the guest is position x+1, the guest is validated. However, the value of x may be defined to be relatively small (10 or less) so that guests are not encouraged to present themselves at an attraction well in advance of gaining an entry position. Validity is indicated to the guest via near field communication to the AW **110** or one or both of a notification on the AW **110** or via a notification on the attraction station **166** (e.g., a tone or display).

[0023] Once the guest engages the queue entry post **168**, the guest's AW **110** will notify the guest (e.g., via a tone, vibration, illuminator) of being added to the virtual queue. For example, the AW **110** may receive a signal to cause the displayed information on the AW **110** to change. Further, the post **168** may additionally or alternatively provide a notification of successful addition to the queue. The notification may be generated and/or communicated by a central virtual queue control system to the AW **110**. In another embodiment, the notification is generated and/or communicated by the queue entry post **168**. In yet another embodiment, the guest **120** may enter the virtual queue by walking to a virtual queue station, which may be implemented as a queue kiosk **172** (e.g., a single device that displays the names and wait times for all virtual queuing attractions in the park or park area). Queue kiosks **172** may be located at the entry or exit of each attraction and in a central location within each park area **152**. The guest **120** selects the queue he/she wishes to enter and engages (e.g., taps) the kiosk with his/her AW **110**. Once the guest **120** engages the queue kiosk **172**, the guest's AW **110** will notify the guest **120** (e.g., via a tone, vibration, illuminator) of being added to the virtual queue. For example, the AW **110** may receive a signal to cause the displayed information on the AW **110** to change. Further, the kiosk **172** may additionally or alternatively provide a notification of successful addition to the queue. The notification to the AW **110** may be communicated via a near field communicator of the queue kiosk **172**. Alternatively, the notification to the AW **110** may be communicated via a long or medium range communicator and may be communicated from a central control system and not from the queue kiosk **172**.

[0024] In another embodiment, the guest **120** must physically go the area of a particular attraction and engage with the designated queue entry post **168** (e.g., an attraction station) for that attraction to enter the queue. That is, virtual queue entry is mediated only via the designated queue entry post (or posts) **168** that are physically co-located with the attraction. In this manner, the guest is encouraged to see an individual ride **148** and determine if the ride is of interest before entering the ride virtual queue. The central queue control system receives the communication from the post **168** or kiosk **172** and adds the guest to the appropriate virtual queue. The addition may be based on a time stamp or a counter. For example, for attractions that have multiple tap-in posts **168**, the guests may be added based on the individual time stamp of the tap-in event and on a first-in basis.

[0025] In each of the embodiments discussed above, the guest's AW **110** may display the estimated return time. For example, a display on the AW **110** may provide a time (e.g., 5:02 PM) by which the guest should return to enter a loading group **122**. This time may dynamically change depending on the operational factors (e.g., current ride capacity, other guests leaving the queue, guests with express (e.g., credentials to automatically jump to the front of a physical and/or virtual queue) or very important person (VIP) credentials entering the queue, inclement weather, and/or downtimes). In some embodiments, once the guest **120** has entered a virtual queue (or some limited number of virtual queues), the guest **120** can no longer enter any other virtual queue unless he/she leaves the current virtual queue, either by entering the ride or by entering a different virtual queue. For example, in one embodiment, engaging the post **168** of a ride or attraction overrides any previously existing places in a virtual queue. In this manner, the guest **120** may traverse the park and, upon noting a ride that is of greater interest or that has a shorter wait time, may simply swipe the AW **110** to enter into a new virtual queue and be automatically removed from a previous virtual queue with one action, which permits the guest **120** to minimize engagement with queue devices and enjoy the

park experience.

[0026] Further, if more than one virtual queue can be entered, the difference between wait times for the available virtual queues may be set to be a sufficient time for both to be entered taking into consideration variables such as travel time between rides or attractions. The system may also artificially space multiple virtual queues to optimize the patrons' day and transit time. In one embodiment, if there is no penalty for failure to arrive at a queued attraction, aside from not being able to enter additional queues, the system may permit close-together times but may also account for a certain predicted percentage of no-shows. In another embodiment, the virtual queuing system may only be in effect if the wait time for the current attraction is greater than 10 minutes. In another embodiment, the guest **120** may be permitted to enter two virtual queues at the same time, but may only enter a single virtual queue at a time that is associated with a ride designated as a low capacity ride. For example, certain park rides may have relatively low capacity and, therefore, may develop longer virtual queues than higher capacity rides, which are capable of moving a greater number of guests through the ride in a given period of time. To control the virtual queue length of lower capacity rides, the virtual queue system as provided herein may, in certain embodiments, prevent the guest **120** from entering two low capacity ride virtual queues simultaneously. For example, when the guest **120** is already entered in a low capacity queue, engaging with the designated post **168** of a second low capacity ride may trigger a warning message displayed on a display of the post **168**, e.g., "GUESTS IN LINE FOR DINOSAUR ADVENTURE MAY NOT ENTER THE LINE FOR VOLCANO RUSH. WOULD YOU LIKE TO EXIT THE LINE FOR DINOSAUR ADVENTURE TO JOIN THE LINE FOR VOLCANO RUSH?" The post **168** may then receive a guest selection of YES or NO. If the guest **120** selects no, the engagement with the post **168** of the second low capacity ride is ended. If the guest **120** selects YES, the guest **120** is added to the virtual queue of the second low capacity ride and automatically removed from the virtual queue of the first low capacity ride.

[0027] Present embodiments facilitate monitoring or waiting in the virtual queue. Guests **120** may wait in the virtual queue by experiencing instantaneous capacity attractions (e.g., a wave pool, swimming pool, splash pad, lazy river, a ride with no wait time), visiting food, beverage, or merchandising locations, or simply relaxing (e.g., resting in a lounge chair). If an attraction wait time of a virtual queue changes, this information may be provided via the communication system **106** to the AW **110**, which will notify the wearing guest **120** and display the updated wait time. If a guest **120** wishes to leave a current virtual queue for another virtual queue, he/she can do so by just joining a new virtual queue as set forth in the description of the various embodiments above. If a guest leaves the park (or, in some cases, a park area) while waiting in a virtual queue, he/she is automatically removed from any virtual queues he/she is currently in. Present embodiments may establish no geographical limits within the park while waiting in a virtual queue and guests **120** may be free to go to any location and perform any task within the park.

[0028] Present embodiments encourage initiating and participating in attraction experiences. In some embodiments, the virtual queuing system **100** will notify the guest **120** prior to the guest's ride time. To determine the amount of prior notification time, the system **100** will utilize multiple factors to optimize capacity: current wait time at the attraction, current distance of the guest **120** away from the attraction, the guest's current activity, and the guest's history for arrival speeds from previous virtual queues. Once the guest is notified, the guest **120** travels to the attraction entrance and walks to the load platform, which accommodates the limited standby group **122**. These factors or variables are monitored by the computer system **102** (e.g., a network of computers **302**), which includes at least one processor **304** and at least one memory **306**, via communication with the monitoring sensors **104**. To ensure that the attraction throughput is not starved, a small standby group **122** (less than 10 minutes) may be formed prior to the load platform at each attraction. Once a guest reaches the load platform and enters the ride, he/she is removed from the current virtual queue. After experiencing the attraction, guests **120** can join another virtual queue as described

above (e.g., a post, kiosk, or the like located in the exit path of the attraction).

[0029] Present embodiments also facilitate communication and management of additional data related to park management. For example, the AW **110** may also perform functions other than facilitating queue access. Specifically, the AW **110** may operate as an identification device used for cashless purchases and for validation to access controlled areas. In some embodiments, guest photographs are automatically taken while on each attraction, as triggered by the AW **110**. Such photographs can be purchased by the guest **120** via an Internet portal (e.g., website, app, kiosk). Further, information may be automatically logged by the virtual queuing system **100** for data analysis. This information may include: experienced attractions (including count and order of visit), wait time for each attraction, time it takes for the guest to return to the attraction once notified, entry time into the park, exit time out of the park, amount of money spent via cashless system.

[0030] In accordance with present embodiments, guests to the theme park shall receive a wearable prior to entering the park (e.g., at the park's front gate) or at least prior to entering a portion of the park. The AW **110** will be linked to the guest's personal profile account on a database and will be configured to interact with kiosks distributed throughout the park. This interaction between the AW **110** and the kiosks will allow the guest to reserve and order items in the park. For example, a guest may reserve VQ slots, cabanas, lockers, towels, etc., using self-serve kiosks, enter and secure lockers and cabanas, and allows guests to purchase food, beverages, and items using the credit card attached to the guest profile in the database. When leaving the park, guests will be prompted to return the wearable; the returned wearable is noted to their account, the payment method is disassociated with the returned wearable, and the device is ready to be cleaned for reuse the next day.

[0031] Guests enter virtual queues at the entrances to certain attractions (e.g., rides). Guests secure entry to virtual queues by tapping the wearable at the virtual queue reservation point, kiosk, or ride entry station, which may be positioned at the ride entrances. Once secured, the wearable continues to receive updated information from the park system and wait times are updated and displayed on the guest's wearable. In some embodiments, guests can enter a maximum of two virtual queues and have the virtual queue status displayed on their wearable at any one time. In accordance with present embodiments, attractions in a park may be divided into two classes (e.g., those with a long lead time and those with shorter lead times) and the two VQs a single guest may enter at any one time may be limited to one of each type.

[0032] FIG. **2** is a schematic representation of an AW **110** in accordance with present embodiments. In the illustrated embodiment, the AW **110** includes a housing **400** in the form of a bracelet.

However, in other embodiments, it may include a necklace, a headband, a ring, or other conveniently wearable item. A device **402** may be imbedded in the housing **400**. The device **402** may include several separate or unified components that perform certain functions. In the illustrated embodiment, the device **402** includes a memory/identifier **404**, a power module **406**, a display **408**, an indicator **410**, a near field communicator **412**, a medium range communicator **414**, and a long range communicator **416**. In some embodiments, these features may be limited. For example, one or both of the medium range communicator **414**, and the long range communicator **416** may be receivers only. In other embodiments, the near field communicator **412**, the medium range communicator **414**, and the long range communicator **416** are transceivers. Further, the disclosed communicators may implemented as RFID communicators that are active or passive. In some embodiments, the memory/identifier **404** may include a simple identifier (e.g., an RFID tag), which the system **100** associates with a guest **120**. In operation, the device **402** may operate to at least receive information from the system **100** to provide the user with information (e.g., a return time for a ride). Further, an indicator (e.g., a light, a vibration mechanism, or an audio feature) may provide feedback to the guest **120**. Specifically, the device **402** may communicate with the system **100** via the communication system **106**. In some embodiments, this may include communication from the device **402** to the system **100**. However, in other embodiments, detecting the device **402**

throughout the park area using the monitoring sensors **104** and analyzing such data with the system **100** may provide information related to the device **402** (e.g., wait times experienced by the user **120** associated with the device **402**). In some embodiments, the AW **110** may be essentially passive and indications (e.g., confirmation sounds) may be provided by the system **100** (e.g., a speaker announcing a nickname of the wearer being entered into a particular virtual queue).

[0033] The AW **110** may be designed as a one-size fits all for average guest ages three (3) years and older. The AW **110** may include components configured to securely and wirelessly communicate, via short, medium and long ranges. For example, the AW **110** may be configured to facilitate communication with software databases (e.g., a database including guest information) and other VQ databases. Guests may be given a wearable, which is connected to VQ and park databases such that the guest's unique guest account can be accessed. The AW **110** may be configured to maintain a secure coupling with a guest, avoid water damage, and so forth when worn all day and riding dynamic body waterslides among other experiences.

[0034] The AW **110** is configured for certain functionality based on tapping, e.g., near field communication using a near field communicator **412** to communicate with a corresponding device. In one embodiment, the AW **110** may be configured to have the following functionality: ability to enter a VQ by tapping a VQ entry device (e.g., virtual queue kiosk **172**); and ability to validate a guest's VQ allocation by tapping the wearable to a ride validation device (e.g., at an attraction station **166**). Additional functionality of the AW **110** may include:

[0035] allowing a single tap (e.g., communication with a tap-point, which may include a wireless communication device such as an RFID reader) to associate a wearable with a guest account;

[0036] (1) allowing coordination with a tap-point at a kiosk to reserve a cabana, towel, lounge chair, or to access a user's profile; [0037] (2) allowing coordination with a tap-point at a point-of-sale (POS) system to purchase food, beverages or merchandise; [0038] (3) allowing coordination with a tap-point at a kiosk to reserve a locker; [0039] (4) allowing coordination with a tap-point at a locker to open a fixed locker; [0040] (5) allowing coordination with a tap-point at a locker to open a mobile locker; [0041] (6) allowing coordination with a tap-point at a special effects station to trigger pre-programmed effects (e.g., light show, water effects, selfie station); and [0042] (7) allowing a medium range reader to coordinate detection of a specific wearable with a database to inform a photo system of a user's identity.

[0043] Other functionality may be mediated by medium or long range communication, including:

[0044] (1) ability to display current VQ status on the wearable; [0045] (2) ability to receive updated VQ status wirelessly to the wearable; [0046] (3) ability to display a VQ progress indication without wireless signal; [0047] (4) allowing a medium range reader to coordinate detection of a specific wearable with a database to establish location awareness for user heat mapping and tracking; and [0048] (5) facilitating provision of alerts and messages displayed on the wearable via wireless signal, near field communication (NFC) and ultra-high frequency (UHF).

[0049] The AW **110** may include no connectors. The AW **110** may be configured to wirelessly and securely output an identification (ID) that is connected to the guest account in a park database and a VQ database. The AW **110** may be configured to display information via an electronic display. The AW **110** may be configured to transmit and receive data wirelessly, at approximate distances represented by: [0050] 1. Near field: less than five (5) centimeters (two-way proximity)-send/receive via the near field communicator **412**; [0051] 2. Medium range: up to anywhere between one-half (0.5) and six (6) meters (one-way medium range)-send via the medium range communicator **414**; and [0052] 3. Long range: up to anywhere between 10 to 100 meters (one way and/or two-way long range, depending upon wireless technology selected) via the long range communicator. In one embodiment, the long range communicator may be a receiver only and may not be capable of two-way communication.

[0053] The AW **110** may incorporate a battery powered system configured to provide continuous power to the wearable which exceeds 100 days of 12 hour per day normal guest usage. This

requirement represents approximately one (1) year of guest usage. The AW **110** may be configured to communicate at approximately less than five (5) centimeters between wearable to tap point. Latency target associated with this may be less than 100 milliseconds. With respect to two-way proximity communication, the AW **110** may be configured to communicate wirelessly approximately at less than five (5) centimeters between the wearable to tap point. Latency target associated with this may be less than 100 milliseconds. The AW **110** may be configured to send identification information to a tap-point module, and the tap-point module will return with VQ data for a particular attraction (e.g., ride). With respect to medium range (<6 m) wireless communication, the AW **110** may communicate wirelessly at distances of approximately up to one half (0.5) to (6) meters, at speeds up to 10 km/h. With respect to long range (10-100 m) communication, the AW **110** may be configured to communicate wirelessly, at distances approximately up to 10 to 100 meters such that data is received once every ten (10) minutes. With respect to standards and protocols, the AW **110** may be configured to meet ISO 14443 specification requirements for NFC communication. Mifare, DesFire or other functional equivalent tag type compliance with all levels of ISO 14443 specifications with advanced encryption standard (AES) hardware cryptographic engine shall be used for security application. Microcontroller unit (MCU) with AES encryption engine may be used to develop enhanced authentication protocol for two-way proximity and medium range communication. Long range aspects may be configured to support an appropriate security management layer.

[0054] The AW **110** may be configured to record and store the latest VQ data received by the software system. For example, the AW **110** may be configured to store information as required by the locker system. The AW **110** may contain active and passive communication devices, which can be tapped on specific tap points within the park to communicate a wearable ID to an associated database. In one embodiment, a total latency from tap point to system response will be <**250** milliseconds. The AWs **110** may also be configured to receive dynamic (wireless) updates as well as allow the system to track wearables as they pass through proximity detection portals.

[0055] The AW **110** may be configured to receive initial VQ data at a VQ allocation tap-point. Once the data is received from the initial VQ allocation tap-point, the AW **110** may receive dynamic VQ updates at a minimum rate of every ten (10) minutes, or as required to maximize battery capacity while still updating guests on a schedule that is perceived to be relevant by the guests while on the park premises.

[0056] The AW **110** may be configured to receive, store, and display information associated with up to two virtual queues (or more). For example, VQ data assigned to other guests associated with a guest may be displayed. VQ data for display on the AW **110** may include: [0057] 1. When a new VQ is added; activated at the virtual queue allocation tap-point; [0058] 2. When the wearable is activated; and [0059] 3. When a VQ time is within **15** minutes of the guest's entry window (e.g., when the guest can ride); and Fifteen (15) minutes prior to the guest's entry window, the AW **110** may start and display a countdown. The countdown may be a numeric countdown (with different time period updates) (1 sec, 1 min, 15 min, etc). The countdown update rate may adjust as the patron's ride time gets closer to the actual time (e.g. 15 min left, the clock updates every 30 seconds instead of every 5 min). The countdown may also be a graphical representation of time remaining (progress bar, hourglass, analog clock) or a color representation of time remaining (Red, Yellow, Green).

[0060] The AW **110** may be configured to interact with proximity detection devices which will enable guest location tracking by communicating with walk-through portals located throughout the park. The AW **110** may be configured to interact with proximity detection of a photo system.

[0061] The AW **110** may include a display that is readable in direct sunlight. Further, the AW **110** may be configured such that no active cooling is required, to withstand daily cleaning in a dedicated wearable washer subjected to temperatures no greater than 60° Celsius, and to withstand mild detergents (including bleach and/or iodine) for disinfecting. The AW **110** may contain self-

testing firmware that cycles through a self-test and indicate that all systems are running properly or indicate that the AW **110** requires service. The AW **110** may include a battery that provides continuous power to the wearable which exceeds 100 days of 12 hours per day of normal guest usage; battery life. This requirement represents approximately one (1) year of guest usage. The AW **110** may be configured such that it has a unit life that exceeds 100 days of normal guest usage, which corresponds to approximately 1 year. The AW **110** may be configured to withstand daily inspection, cleaning, and self-testing. The AW **110** may have no internal serviceable parts. The AW **110** may be configured to function properly between 0° Celsius and 45° Celsius at 100% humidity. The AW **110** may be configured to operate after storage conditions between 0° Celsius and 60° Celsius. The AW **110** may be configured to have a minimum Submersible IP68 rating for: [0062] 1. Dust tight; and [0063] 2. Immersion in pool water to a depth of one (1) meter for 30 minutes. [0064] The AW **110** may be configured to withstand prolonged one (1) hour exposure to temperatures of 40° Celsius environmental conditions and then be subjected to being submerged into 16° Celsius fresh water for five (5) minutes. The AW **110** may be configured to function properly as designed, with minimal cosmetic impacts, when dropped from a height of three (3) feet onto a flat concrete surface. Further, the AW **110** may be configured to continue to function properly as designed, regardless of cosmetic impact, when dropped from a height of ten (10) feet onto a flat concrete surface. The AW **110** may be configured to exhibit no mechanical defects when exposed to the equivalent of 3,000 hours of full sunlight exposure. This may be confirmed by testing in accordance with ISO 4892 UV Exposure: Plastics-Methods of Exposure to Laboratory Light Sources. The AW **110** may be configured to exhibit minimal discoloration when exposed to the equivalent of 3,000 hours of full sunlight exposure. This may be tested in accordance with ASTM E1347 Standard Practice for Color Analysis. The AW **110** may be configured to not cause skin irritation, rash, discoloration, or other negative effect when worn continuously for 12 hours. The AW **110** may include a wearable/clasp assembly, that maintains a tensile strength between five (5) and thirty (30) pounds per square inch to ensure the wearable remains attached to the guest during normal use, but will break free from the guest without causing injury when caught or snagged on an unintended obstacle. The AW **110** may be configured to continue to function properly, with minimal cosmetic impact, when subjected to a gravitational impact of two (2) Gs. This may be demonstrated by testing in accordance with ASTM D256-10 Standard Test Methods for Determining the Izod Pendulum Impact Resistance of Plastics. The AW **110** may be configured to continue to function properly, with minimal cosmetic impact, when subjected to five (5) hours of vibration at prevention of significant deterioration (PSD) of 0.02, to simulate the vibration of truck delivered shipping. This may be demonstrated by testing in accordance with SAE J1455. [0065] The AW **110** may be configured to exhibit minimal cosmetic damage when exposed to the equivalent of five (5) days or 50 hours of normal guest use in a water park. This may be tested in accordance with ASTM D7027-13, Standard Test Method for Evaluation of Scratch Resistance of Polymeric Coatings and Plastics using an Instrumented Scratch Machine. The display of the AW **110** may be configured to exhibit minimal cosmetic damage when exposed to the equivalent of 5 days or 50 hours of use in a water park. This may be tested in accordance with ASTM F735-11, Standard Test Method for Abrasion Resistance of Transparent Plastics and Coatings Using the Oscillating Sand Method. The AW **110** may be configured to not negatively react mechanically or cosmetically when exposed to the following: fresh water, pool chlorine, soda, blood, sweat, tears, alcohol, vomit, sunscreen, insect repellent, urine, or saliva. The AW **110** may be configured to operate nominally with no adverse effects in a pool water environment with the following water quality conditions: [0066] 1. pH-range: 7.3 to 7.8; [0067] 2. Chlorine range-range: 1.0 to 10.0; [0068] 3. Total alkalinity-range: 70 to 120; [0069] 4. Calcium hardness-range: 200 to 400; and [0070] 5. Total dissolved solids-average: 1500. [0071] A VQ tap-point, which may be implemented as an attraction station **166**, virtual queue post **168**, and/or virtual queue kiosk **172**, as well as locker rental stations, cabana rental stations, special

effects stations etc., may include hardware electrical components that are configured to provide a generic unit to be installed inside of themed enclosures. VQ tap-points may be configured to securely and wirelessly communicate with VQ wearables and other types of radio-frequency identification (RFID)/NFC chips within the HF-ISO 14443 A/B range and may include wired communication to a software database. The VQ tap-point may include a RFID proximity reader, outputs for visual indication of the read LED's within the module, and outputs to connect to the software database. A VQ tap-point may include mounting features (e.g., quick disconnects and outdoor rated plugs) to allow it to be easily replaced with simple hand tools. The VQ tap-point includes features for outward visual indication of successful/unsuccessful tap/notification of exception or error display.

[0072] With respect to user experiences with VQ tap-point and VQ wearables, as guests “tap” the module (e.g., establish communication between the AW **110** and the VQ tap-point), the following may occur in certain embodiments: [0073] 1. Mode 1: Activate VQ wearable from a standby state upon guest entry to the park; [0074] 2. Mode 2: Read VQ wearable to secure a position in the virtual queue; [0075] 3. Mode 3: Read VQ wearable to enter the attraction (e.g., ride); [0076] 4. Mode 4: Read VQ wearable to check VQ reservation; [0077] 5. Mode 5: Read VQ wearable to notify guest of an exception; and [0078] 6. Mode 6: Guest is notified on the AW **110**, by way of tap, that there has been an exception in their VQ. This could be a ride closure, park closure or overall error.

[0079] The VQ tap-point may be configured to receive data two ways: (1) wirelessly from the wearable at distances of less than five centimeter, and (2) via wired Ethernet connection from the software database. The VQ tap-point may contain a main tap point, as well as I/O for a supplemental tap point. Light (or other) outputs may be red, green, blue or white (RGBW) in color and may be mountable into lenses of the themed enclosures. Quantity of lights may be determined based on design of the module, i.e. two (2) eyes in a face theme, and so forth. The VQ tap-point may emit sounds via external speakers between 100 Hz-5 kHz, up to 80 dB, measured at one (1) meter, and may also contain an optional secondary output for a subwoofer. The VQ tap-point may display ride relevant information (e.g., current ride wait time, current time of day and so forth) via, for example, a full color display, and may display guest photos on another separate display; viewable by park team members. In one embodiment, the VQ tap-point may contain a microphone for automatic adjustments to the gain of the loudspeaker. The VQ tap-point may also have a hardwired Ethernet connection to the software system(s).

[0080] With respect to two-way proximity communication (distance and latency), the VQ tap-point may communicate at less than five (5) centimeters from a wearable to tap point. Target latency may be less than 100 milliseconds. The VQ tap-point may receive identification data from a VQ wearable, may send that data to the software database to determine VQ time, receive VQ time back from database, and wirelessly communicate the virtual queue time to the AW **110**. The wearable ID, VQ location and VQ time may be written to the park database.

[0081] With respect to communication with other network systems, the VQ tap-point may communicate with the virtual queue database and other databases (e.g., park databases). ISO 14443 may be used for communication if NFC is the proposed solution. A multiport control unit (MCU) with AES encryption engine, along with 14443A/B NFC transponder, may be used to develop enhanced authentication protocol for two-way proximity. Regarding performance of taps in accordance with present embodiments, guests may tap their VQ wearable to the VQ tap-point hardware to enter virtual queues. Also guests may tap an attraction (e.g., ride) validation module hardware to verify an entitlement when the guest has waited in the virtual queue to physically enter the ride. The VQ tap-point may respond to the tap with appropriate sounds and lights. Total system target latency from tap to system response may be less than or equal to 250 milliseconds.

[0082] The VQ tap-point may receive updated VQ times each time a guest taps in. Further, the VQ tap-point may respond in multiple ways: [0083] 1. VQ mode-to indicate success/failure of VQ

transaction. [0084] 2. Return mode-to indicate guest availability to ride; time, correct ride, and so forth.

[0085] The VQ tap-point may receive updated ride wait times to be displayed every one minute. The VQ tap-point may function properly between 0° Celsius to 45° Celsius, at 100% humidity. The VQ tap-point may survive storage conditions between -10° Celsius to 60° Celsius, at 90% humidity. With respect to ingress protection, the VQ tap-point may be designed as a NEMA Type 4. The VQ tap-point may continue to function properly when dropped from a height of three (3) feet onto a flat concrete surface. Packaging may completely protect the module from any cosmetic or functional defects when a box is dropped from a height of five (5) feet onto a flat concrete surface.

[0086] Portions of the VQ tap-point that are subjected to direct or indirect sunlight during normal use may comply with UL 746C. The VQ tap-point may continue to function properly, with minimal cosmetic impact, when subjected to 5 hours of vibration testing at PSD of 0.02; to simulate vibration of trucking/shipping. Testing may be performed in accordance with SAE J1455. The VQ tap-point may be designed such that it does not negatively react, mechanically or cosmetically, when exposed to the following conditions: fresh water, pool chlorine, soda, blood, sweat, tears, alcohol, vomit, sunscreen, insect repellent, urine, or saliva. Electro static discharge compliance of the VQ tap-point may be in accordance with IEC 61000 Apr. 2 ESD Immunity Testing. The VQ tap-point may exhibit no mechanical and minimal cosmetic damage when exposed to the equivalent of 3,000 hours of salt spray exposure. Testing of this may be done in accordance with ASTM B117-11 Standard Practice for Operating Salt Spray (Fog) Apparatus. The VQ tap-point may comply with Restriction of Hazardous Substance Directive 2002/95/EC. Aspects of the VQ tap-point may be easily replaceable and connectable using outdoor rated pluggable connections for the following components: [0087] 1. Displays; [0088] 2. Power; [0089] 3. Speakers; [0090] 4. Network; [0091] 5. Antenna modules; and [0092] 6. Tap.

[0093] FIG. 3 is a block diagram of a virtual queue system **500** that may be implemented to manage queues in a theme park. The system **500** includes park devices **501** such as a virtual queue control system **502** in communication with one or more VQ tap-points. While the system is depicted with an embodiment including an attraction station **166** and virtual queuing station **172**, it should be understood that these are examples of park devices **501** that are included in the system **500**, and that other VQ tap-points or park devices **501** may be included that have similar hardware components. In addition, the functionality of the virtual queue system **500** may be distributed between the park devices **501** and the AW **110**. In one embodiment, the central controller functionality is implemented via the virtual queue control system **502**, which is remote from the attraction stations **166**. Each park ride or attraction may be associated with one or more dedicated virtual attraction stations **166** that receive queue inputs from guests. That is, in certain embodiments, each attraction station **166** may facilitate entry into the virtual queue of only one attraction. One or both of the virtual queue control system **502** and the virtual queuing station **172** may include communications circuitry (e.g., communications circuitry **504** or **552**), such as antennas, radio transceiver circuits, and signal processing hardware and/or software (e.g., hardware or software filters, A/D converters, multiplexers amplifiers), or a combination thereof, and that may be configured to communicate over wired or wireless communication paths via IR wireless communication, satellite communication, broadcast radio, Microwave radio, Bluetooth, Zigbee, Wifi, UHF, NFC, etc. Such communication may also include intermediate communications devices, such as radio towers. In one embodiment, the communication between the attraction station **166** and the virtual queue control system **502** is wired.

[0094] In addition, one or both of the virtual queue controller or control system **502** and the virtual queuing station **172** may include a memory device (e.g., memory device **508** or **510**) for storing instructions executable by a processor (e.g., processor **512** or **514**) to perform the methods and control actions described herein. For example, the processor **512** may execute instructions for dynamic virtual queue management based on inputs from the virtual queuing station **172** as well as

data on guest entry into a ride and guest exit from a park. Additional inputs to dynamic queue management may include guest location within the park. For example, a reminder to return to the attraction may be based at least in part on the guest's location relative to the attraction, as determined via wireless signal or global positioning system (GPS) information from the guest active wearable or by a guest's last tap-in location with the virtual queuing station or other tap-in device. The system **500** may store guest locations during a park visit to create an accessible log of guest locations within the park for use in predicting guest current and future locations. If the guest is estimated to be located within a first distance or within a first zone relative to the attraction, the return reminder or message is sent to return within a first time (e.g., "YOU CAN LEAVE IN 20 MINUTES FOR VOLCANO RUSH"), which accounts for a shorter travel time to the attraction. If the guest is instead in a farther second zone or a farther estimated second distance, the return reminder or message accounts for the longer travel time by providing an earlier return time (e.g., "PLAN TO LEAVE IN 5 MINUTES FOR VOLCANO RUSH"), to account for longer walking times to the attraction. In this manner, guests at similar positions in the virtual queue but at different locations within the park are estimated to return to the attraction within the same approximate time window.

[0095] The processor may include one or more processing devices, and the memory may include one or more tangible, non-transitory, machine-readable media. By way of example, such machine-readable media can include RAM, ROM, EPROM, EEPROM, or optical disk storage, magnetic disk storage or other magnetic storage devices, or any other medium which can be used to carry or store desired program code in the form of machine-executable instructions or data structures and which can be accessed by the processor or by other processor-based devices (e.g., mobile devices). For example, the virtual queue control system **502** or the virtual queuing station **172** may be accessed by an operator interface **520**, e.g., a computer-based workstation or a mobile device, and/or may include an input/output interface **516** and a display (e.g., display **532**).

[0096] The virtual queuing station **172** or the attraction station **166** receives signals (e.g., wireless signals, such as RF signals) from a guest AW **110**. The AW **110** may, in one embodiment, tap in to the virtual queuing station (e.g., via a hand wave or via positioning the AW **110** within the reading zone of the virtual queuing station **172**) where it send the signal via NFC and receives signal back and updates via NFC. Additionally, components of the system (e.g., the virtual queuing station **172** and/or the AW **110**) may be actively listening for a wireless broadcast and may update the display upon receipt of the appropriate broadcast. Another option is a system where the attraction stations **166** are dumb/passive and the AW **110** reads the totem location and transmits the request through a wireless network bypassing the need to have the virtual queuing station **172** read the AW **110**. These signals may, in turn, be communicated to the virtual queue control system **502** to add the guest associated with the AW **110** to the virtual queue.

[0097] While the attraction station **166** may also facilitate guest entry into a virtual queue in a manner similar to the virtual queuing station **172** and may include similar components (e.g., memory **556**, processor **554**, communications circuitry **552**), the attraction station **166** may also be implemented as an automatic gate or reader such that the AW **110** as it passes through the attraction station **166** is automatically read and the guest associated with the AW **110** is indicated as entering the ride and, therefore, is automatically removed from the virtual queue. It should be understood that certain features of the virtual queue control system **502** may additionally or alternatively be implemented locally at the attraction station **166**. Further, the attraction station **166** may also include notification devices **558** such as one or more of a display, speaker, lights, to indicate successful validation of the AW **110** for ride entry.

[0098] The virtual queue system **500** may, in certain embodiments, manage a total guest experience to ensure that an individual guest may experience a minimum number of rides or experiences per day. For example, based on the virtual queue load for various attractions, the virtual queue system **500** may permit entry into a predetermined number of queues at the beginning of the day.

Alternatively, the virtual queue system **500** may dynamically present ride options to each guest at a central kiosk (e.g., queue kiosk **172**, see FIG. **1**). That is, while in certain embodiments, the virtual queue control system is implemented without any central queue kiosk that permits selection and virtual queue entry to multiple queues of different attractions at a single device and within a single interaction, in other embodiments one or more central kiosks may mediate entry into multiple virtual queues at once.

[0099] While only certain features of the present embodiments have been illustrated and described herein, many modifications and changes will occur to those skilled in the art. It is, therefore, to be understood that the appended claims are intended to cover all such modifications and changes as fall within the true spirit of the present disclosure. Further, it should be understood that certain elements of the disclosed embodiments may be combined or exchanged with one another.

Claims

1. A method comprising: receiving a user device identification from a first virtual queue station associated with a first virtual queue of a first attraction; adding the user device identification received from the first virtual queue station to the first virtual queue of the first attraction; receiving the user device identification from a second virtual queue station associated with a second virtual queue of a second attraction; adding the user device identification received from the second virtual queue station to the second virtual queue of the second attraction; and removing the user device identification from the first virtual queue of the first attraction in response to adding the user device identification to the second virtual queue of the second attraction.
2. The method of claim 1, comprising communicating to a user device associated with the user device identification an indication related to the second virtual queue of the second attraction.
3. The method of claim 2, wherein communicating the indication related to the second virtual queue of the second attraction comprises: displaying, via a display associated with the user device, a position in the second virtual queue of the second attraction; and displaying, via the display associated with the user device, a notification that the user device has been removed from the first virtual queue of the first attraction.
4. The method of claim 1, comprising: receiving the user device identification from a tap station associated with the first virtual queue station; and linking the user device identification from the tap station to a user identification.
5. The method of claim 4, comprising: acquiring, via a camera associated with the tap station, an image of a user; linking the image to the user identification; and using the image as an entry credential for the user to enter the first virtual queue or the second virtual queue.
6. The method of claim 1, comprising: receiving, via a service tap station, the user device identification from a signal communicator of a user device; and coordinating a reservation of a service item in response to receiving the user device identification from the service tap station.
7. The method of claim 1, wherein removing the user device identification from the first virtual queue of the first attraction is based at least in part on an attraction type of the first attraction and an attraction type of the second attraction.
8. The method of claim 1, comprising: receiving the user device identification from an attraction station located proximate to the second attraction; and validating access to the second attraction based on a position within the second virtual queue of the second attraction being less than a threshold value.
9. The method of claim 1, wherein removing the user device identification from the first virtual queue of the first attraction comprises receiving a confirmation input from a user to remove the user device identification from the first virtual queue.
10. The method of claim 1, wherein the user device identification is associated with a user device, and wherein the user device is a waterproof bracelet or wearable device.

- 11.** A method, comprising: receiving a first request to join a first virtual queue associated with a first attraction from a first tap point associated with the first virtual queue, wherein the first request comprises a user identification; adding the user identification to the first virtual queue of the first attraction based on receiving the first request; receiving a second request to join a second virtual queue associated with a second attraction from a second tap point associated with the second virtual queue, wherein the second request comprises the user identification; adding the user identification to the second virtual queue of the second attraction based on receiving the second request; and removing the user identification from the first virtual queue of the first attraction in response to adding the user identification to the second virtual queue of the second attraction.
- 12.** The method of claim 11, wherein receiving the first request and the second request comprises: receiving a first signal from a signal communicator of a user device at the first tap point, wherein the first signal is indicative of a user device identification; receiving a second signal from the signal communicator of the user device at the second tap point, wherein the second signal is indicative of the user device identification; and linking the user device identification to the user identification.
- 13.** The method of claim 12, comprising: receiving the user device identification from an attraction station located proximate to the second attraction; and validating access to the second attraction based on a position of the user device identification within the second virtual queue being less than a threshold value.
- 14.** The method of claim 11, comprising communicating to a user device associated with the user identification an indication related to the second virtual queue of the second attraction.
- 15.** The method of claim 11, comprising: determining a first attraction type of the first attraction; determining a second attraction type of the second attraction; and removing the user identification from the first virtual queue of the first attraction based on the first attraction type of the first attraction and the second attraction type of the second attraction.
- 16.** The method of claim 11, comprising: acquiring, via a camera, an image of a user; linking the image to the user identification; and using the image as an entry credential for the user to enter the first virtual queue or the second virtual queue.
- 17.** A method, comprising: receiving a first communication from a user device, wherein the first communication comprises a first request to join a first virtual queue of a first attraction based on a first interaction between the user device and a first tap station associated with the first attraction; adding a user device identification associated with the user device to the first virtual queue based on the first interaction between the user device and the first tap station associated with the first attraction; receiving a second communication from the user device, wherein the second communication comprises a second request to join a second virtual queue of a second attraction based on a second interaction between the user device and a second tap station associated with the second attraction; adding the user device identification associated with the user device to the second virtual queue based on the second interaction between the user device and the second tap station associated with the second attraction; and removing the user device identification from the first virtual queue of the first attraction in response to adding the user device identification to the second virtual queue of the second attraction.
- 18.** The method of claim 17, comprising: receiving a third communication from the user device based on a third interaction between the user device and an attraction station associated with and located proximate to the first attraction or the second attraction, wherein the third communication is indicative of a third request to gain access to the first attraction or the second attraction; and validating access to the first attraction or the second attraction based on a position within the first virtual queue or the second virtual queue being less than a threshold value.
- 19.** The method of claim 17, comprising: acquiring, via a camera, an image of a user, linking the image to the user device identification; and using the image as an entry credential for the user to enter the first virtual queue or the second virtual queue.
- 20.** The method of claim 17, comprising: receiving, via a service tap station, a third communication

from the user device, wherein the third communication is indicative of a reservation of a service item; and coordinating the reservation of the service item in response to receiving the third communication from the service tap station.
