SHEAR THICKENING FLUID ENABLED OBJECT MOVEMENT CONTROL MECHANISM

Abstract

A door closer system to control motion of a door includes a shear thickening fluid (STF), a chamber for the STF, and a piston within the chamber. The door closer system further includes a plunger coupled to the piston and to a spring with a motion conversion aspect to mechanically join motion of the door with movement of the piston and to provide compression of the spring based on an opening motion of the door. The motion conversion aspect is further configured to cause the spring to hold stored energy as a result of the opening motion of the door, the spring to release the stored energy to facilitate a closing motion of the door, and regulating a velocity of the closing motion of the door as a result of the piston causing an increasing viscosity of the STF to provide a soft close feature.

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS [0001] The present U.S. Utility patent application claims priority pursuant to 35 U.S.C. § 120 as a continuation-in-part of U.S. Utility application Ser. No. 18/220,400, entitled “MULTI-SHEAR THICKENING FLUID ENABLED OBJECT MOVEMENT CONTROL MECHANISM” filed Jul. 11, 2023, allowed, which claims priority pursuant to 35 U.S.C. § 120 as a continuation-in-part of U.S. Utility application Ser. No. 17/539,084, entitled “MULTI-SHEAR THICKENING FLUID ENABLED OBJECT MOVEMENT CONTROL MECHANISM” filed Nov. 30, 2021, issued Jan. 2, 2024 as U.S. Pat. No. 11,859,642, which claims priority pursuant to 35 U.S.C. § 119(e) to U.S. Provisional Application No. 63/250,700, entitled “DILATANT FLUID BASED OBJECT MOVEMENT CONTROL MECHANISM” filed Sep. 30, 2021, expired, all of which are hereby incorporated herein by reference in their entirety and made part of the present U.S. Utility patent application for all purposes.

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT [0002] Not Applicable.

INCORPORATION-BY-REFERENCE OF MATERIAL SUBMITTED ON A COMPACT DISC [0003] Not Applicable.

BACKGROUND OF THE INVENTION

Technical Field of the Invention

[0004] This invention relates generally to systems that measure and control mechanical movement and more particularly to sensing and controlling of a linear and/or rotary movement mechanism that includes a chamber with dilatant fluid (e.g., a shear thickening fluid).

Description of Related Art

[0005] Many mechanical mechanisms are subject to undesired movement that can lead to annoying sounds, property damage and/or loss, and personal injury and even death. Desired and undesired movements of the mechanical mechanisms may involve a wide range of forces. A need exists to control the wide range of forces to solve these problems.

Description

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING(S)

[0006] FIG. 1A is a schematic block diagram of an embodiment of a mechanical and computing system in accordance with the present invention;

[0007] FIG. 1B is a graph of viscosity vs. shear rate for an aspect of an embodiment of a mechanical and computing system in accordance with the present invention;

[0008] FIG. 1C is a graph of plunger velocity vs. force applied to the plunger for an aspect of an embodiment of a mechanical and computing system in accordance with the present invention;

[0009] FIG. 2A is a schematic block diagram of an embodiment of a computing entity of a computing system in accordance with the present invention;

[0010] FIG. 2B is a schematic block diagram of an embodiment of a computing device of a computing system in accordance with the present invention;

[0011] FIG. 3 is a schematic block diagram of another embodiment of a computing device of a computing system in accordance with the present invention;

[0012] FIG. 4 is a schematic block diagram of an embodiment of an environment sensor module of a computing system in accordance with the present invention;

[0013] FIGS. 5A-5D are schematic block diagrams of another embodiment of a mechanical and computing system illustrating an example of determining operational aspects in accordance with the present invention;

[0014] FIGS. 6A-6C are schematic block diagrams of another embodiment of a mechanical and computing system illustrating an example of controlling operational aspects in accordance with the present invention;

[0015] FIGS. 7A-7D are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of determining operational aspects in accordance with the present invention;

[0016] FIGS. 8A-8C are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects in accordance with the present invention;

[0017] FIGS. 9A-9C are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects in accordance with the present invention;

[0018] FIGS. 10A-10C are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects in accordance with the present invention;

[0019] FIGS. 11A-11B are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects in accordance with the present invention;

[0020] FIGS. 12A-12B are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects in accordance with the present invention;

[0021] FIGS. 13A-13B are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects in accordance with the present invention;

[0022] FIGS. 14A-14B are schematic block diagrams of an embodiment of a mechanical system illustrating an example of controlling operational aspects in accordance with the present invention;

and

[0023] FIGS. 15A-15E are schematic block diagrams of an embodiment of a mechanical system illustrating an example of controlling operational aspects in accordance with the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0024] FIG. 1A is a schematic block diagram of an embodiment of a mechanical and computing system that includes a set of head units **10-1** through **10-N**, objects **12-1** through **12-3**, computing entities **20-1** through **20-N** associated with the head units **10-1** through **10-N**, and a computing entity **22**. The objects include any object that has mass and moves. Examples of an object include a door, an aircraft wing, a portion of a building support mechanism, and a particular drivetrain, etc.

[0025] The cross-sectional view of FIG. 1A illustrates a head unit that includes a chamber **16**, a piston **36**, a plunger **28**, a plunger bushing **32**, and a chamber bypass **40**. The chamber **16** contains a

shear thickening fluid (STF) **42**. The chamber **16** includes a back channel **24** and a front channel **26**, where the piston partitions the back channel **24** and the front channel **26**. The piston **36** travels axially within the chamber **16**. The chamber **16** may be a cylinder or any other shape that enables movement of the piston **36** and compression of the STF **42**. The STF **42** is discussed in greater detail with reference to FIGS. **1B** and **1C**.

[0026] The plunger bushing **32** guides the plunger **28** into the chamber **16** in response to force from the object **12-1**. The plunger bushing **32** facilitates containment of the STF within the chamber **16**. The plunger bushing **32** remains in a fixed position relative to the chamber **16** when the force from the object moves the piston **36** within the chamber **16**. In an embodiment the plunger bushing **32** includes an O-ring between the plunger bushing **32** and the chamber **16**. In another embodiment the plunger bushing **32** includes an O-ring between the plunger bushing **32** and the plunger **28**.

[0027] The piston **36** includes a piston bypass **38** between opposite sides of the piston to facilitate flow of a portion of the STF between the opposite sides of the piston (e.g., between the back channel **24** and the front channel **26**) when the piston travels through the chamber in an inward or an outward direction.

[0028] Alternatively, or in addition to, the chamber bypass **40** is configured between opposite ends of the chamber **16**, wherein the chamber bypass **40** facilitates flow of a portion of the STF between the opposite ends of the chamber when the piston travels through the chamber in the inward or outward direction (e.g., between the back channel **24** and the front channel **26**).

[0029] In alternative embodiments, the piston bypass **38** and the chamber bypass **40** includes mechanisms to enable STF flow in one direction and not an opposite direction. In further alternative embodiments, a control valve within the piston bypass **38** and/or the chamber bypass **40** controls the STF flow between the back channel **24** and the front channel **26**.

[0030] The plunger **28** is operably coupled to a corresponding object by one of a variety of approaches. A first approach includes a direct connection of the plunger **28** to the object **12-1** such that linear motion in any direction couples from the object **12-1** to the plunger **28**. A second approach includes the plunger **28** coupled to a cap **44** which receives a one way force from a strike **48** attached to the object **12-2**. A third approach includes a pushcap **46** that receives a force from a rotary-to-linear motion conversion component that is attached to the object **12-3**. In an example, the object **12-3** is connected to a camshaft **110** which turns a cam **109** to strike the pushcap **46**.

[0031] In an embodiment, two or more of the head units are coupled by a head unit connector **112**. When so connected, actuation of a piston in a first head unit is essentially replicated in a piston of a second head unit. The head unit connector **112** includes a mechanical element between plungers of the two or more head units and/or direct connection of two or more plungers to a common object. For example, plunger **28** of head unit **10-1** and plunger **28** of head unit **10-2** are directly connected to object **12-1** when utilizing a direct connection.

[0032] Further associated with each head unit is a set of emitters and a set of sensors. For example, head unit **10-N** includes a set of emitters **114-N-1** through **114-N-M** and a set of sensors **116-N-1** through **116-N-M**. Emitters includes any type of energy and or field emitting device to affect the STF, either directly or indirectly via other nanoparticles suspended in the STF. Examples of emitter categories include light, audio, electric field, magnetic field, wireless field, etc. Specific examples of fluid manipulation emitters include a variable flow valve associated with a bypass or injector or similar, a mechanical vibration generator, an image generator, a light emitter, an audio transducer, a speaker, an ultrasonic sound transducer, an electric field generator, a magnetic field generator, and a radio frequency wireless field transmitter. Specific examples of magnetic field emitters include a Helmholtz coil, a Maxwell coil, a permanent magnet, a solenoid, a superconducting electromagnet, and a radio frequency transmitting coil.

[0033] Sensors include any type of energy and/or field sensing device to output a signal that represents a reaction, motion or position of the STF. Examples of sensor categories include bypass valve position, mechanical position, image, light, audio, electric field, magnetic field, wireless

field, etc. Specific examples of fluid flow sensors include a valve opening detector associated with the chamber **16** or any type of bypass (e.g., piston bypass **38**, chamber bypass **40**, a reservoir injector, or similar), a mechanical position sensor, an image sensor, a light sensor, an audio sensor, a microphone, an ultrasonic sound sensor, an electric field sensor, a magnetic field sensor, and a radio frequency wireless field sensor. Specific examples of magnetic field sensors include a Hall effect sensor, a magnetic coil, a rotating coil magnetometer, an inductive pickup coil, an optical magnetometry sensor, a nuclear magnetic resonance sensor, and a caesium vapor magnetometer.

[0034] The computing entities **20-1** through **20-N** are discussed in detail with reference to FIG. **2A**. The computing entity **22** includes a control module **30** and a chamber database **34** to facilitate storage of history of operation, desired operations, and other aspects of the system.

[0035] In an example of operation, the head unit **10-1** controls motion of the object **12-1** and includes the chamber **16** filled at least in part with the shear thickening fluid **42**, the piston **36** housed at least partially radially within the chamber **16**, and the piston **36** is configured to exert pressure against the shear thickening fluid **42** in response to movement of the piston **36** from a force applied to the piston from the object **12-1**. The movement of the piston **36** includes one of traveling through the chamber **16** in an inward direction or traveling through the chamber **16** in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0036] The shear thickening fluid **42** (e.g., dilatant non-Newtonian fluid) has nanoparticles of a specific dimension that are mixed in a carrier fluid or solvent. Force applied to the shear thickening fluid **42** results in these nanoparticles stacking up, thus stiffening and acting more like a solid than a flowable liquid when a shear threshold is reached. In particular, viscosity of the shear thickening fluid **42** rises significantly when shear rate is increased to a point of the shear threshold. The relationship between viscosity and shear rates is discussed in greater detail with reference to FIGS. **1A** and **1B**.

[0037] In another example of operation, the object **12-1** applies an inward motion force on the plunger **28** which moves the piston **36** in words within the chamber **16**. As the piston moves inward, shear rate of the shear thickening fluid **42** changes. A sensor **116-1-1** associated with the chamber **16** of the head unit **10-1** outputs chamber I/O **160** to the computing entity **20-1**, where the chamber I/O **160** includes a movement data associated with the STF **42** as a result of the piston **36** moving inwards. Having received the chamber I/O **160**, the computing entity **20-1** interprets the chamber I/O **160** to reproduce the movement data.

[0038] The computing entity **20-1** outputs the movement data as a system message **162** to the computing entity **22**. The control module **30** stores the movement data in the chamber database **34** and interprets the movement data to determine whether to dynamically adjust the viscosity of the shear thickening fluid. Dynamic adjustment of the viscosity results in dynamic control of the movement of the piston **36**, the plunger **28**, and ultimately the object **12-1**. Adjustment of the viscosity affects velocity, acceleration, and position of the piston **36**.

[0039] The control module **30** determines whether to adjust the viscosity based on one or more desired controls of the object **12-1**. The desired controls include accelerating, deaccelerating, abruptly stopping, continuing on a current trajectory, continuing at a constant velocity, or any other movement control. For example, the control module **30** determines to abruptly stop the movement of the object **12-1** when the object **12-1** is a door and the door is detected to be closing at a rate above a maximum closing rate threshold level and when the expected shear rate versus viscosity of the shear thickening fluid **42** requires modification (e.g., boost the viscosity now to slow the door from closing too quickly).

[0040] When determining to modify the viscosity, the control module **30** outputs a system message **162** to the computing entity **20-1**, where the system message **162** includes instructions to immediately boost the viscosity beyond the expected shear rate versus viscosity of the shear thickening fluid **42**. Alternatively, the system message **162** includes specific information on the

relationship of viscosity versus shear rate.

[0041] Having received the system message **162**, the computing entity **20-1** determines a set of adjustments to make with regards to the shear thickening fluid **42** within the chamber **16**. The set of adjustments includes one or more of adjusting STF **42** flow through the chamber bypass **40**, adjusting STF **42** flow through the piston bypass **38**, and activating an emitter of a set of emitters **114-1-1** through **114-N-1**. The flow adjustments include regulating within a flow range, stopping, starting, and allowing in one particular direction. For example, the computing entity **20-1** determines to activate emitter **114-1-1** to produce a magnetic field such as to interact with magnetic nanoparticles within the STF **42** to raise the viscosity. The computing entity **20-1** issues another chamber I/O **160** to the emitter **114-1-1** to initiate a magnetic influence process to boost the viscosity of the STF **42**.

[0042] In an alternative embodiment, the computing entity **22** issues another system message **162** to two or more computing entities (e.g., **20-1** and **20-2**) to boost the viscosity for corresponding head units **10-1** and **10-2** when the head unit connector **112** connects head units **10-1** and **10-2** and both head units are controlling the motion of the object **12-1**. For instance, one of the head units informs the computing entity **22** that the object **12-1** is moving too quickly inward and the predicted stopping power of the expected viscosity versus shear rate of the STF **42** of the head unit, even when boosted, will not be enough to slow the object **12-1** to a desired velocity or position. When informed that one head unit, even with a modified viscosity, is not enough to control the object **12-1**, the control module **30** determines how many other head units (e.g., connected via the head unit connector **112**) to apply and to dynamically modify the viscosity.

[0043] In yet another alternative embodiment, the computing entity **22** issues a series of system messages **162** to a set of computing entities associated with a corresponding set of head units to produce a cascading effect of altering of the viscosity of the STF **42** of each of the chambers **16** associated with the set of head units. For example, 3 head units are controlled by 3 corresponding computing entities to adjust viscosity in a time cascaded manner. For instance, head unit **10-1** abruptly changes the viscosity to attempt to slow the object **12-1** followed seconds later by head unit **10-2** abruptly changing the viscosity to attempt to further slow the object **12-1**, followed seconds later by head unit **12-3** abruptly changing the viscosity to attempt to further slow the object **12-1**.

[0044] In a still further alternative embodiment, the computing entity **22** conditionally issues each message of the series of system messages **162** to the set of computing entities associated with the corresponding set of head units to produce the cascading effect of altering of the viscosity of the STF **42** of each of the chambers **16** associated with the set of head units only when a most recent adaptation of viscosity is not enough to slow the object **12-1** with desired results. For example, the 3 head units are controlled by the 3 corresponding computing entities to adjust viscosity in a conditional time cascaded manner. For instance, head unit **10-1** abruptly changes the viscosity to attempt to slow the object **12-1** followed seconds later by head unit **10-2** abruptly changing the viscosity if head unit **10-1** was unsuccessful to attempt to further slow the object **12-1**, followed seconds later by head unit **12-3** abruptly changing the viscosity if head unit **10-2** was unsuccessful to attempt to further slow the object **12-1**.

[0045] FIG. **1B** is a graph of viscosity vs. shear rate for an aspect of an embodiment of a mechanical and computing system that includes a chamber, a shear thickening fluid, and a piston that moves through the chamber applying forces on the shear thickening fluid. The shear thickening fluid includes a non-Newtonian fluid since the relationship between shear rate and viscosity is nonlinear.

[0046] A relationship between compressive impulse (e.g., shear rate) and the viscosity of the shear thickening fluid is nonlinear and may comprise one or more inflection points as the piston travels within the chamber in response to different magnitudes of forces and different accelerations. The viscosity of the STF may also be a function of other influences, such as electric fields, acoustical

waves, magnetic fields, and other similar influences. As a first example of a response of a shear thickening fluid, a first range of shear rates in zone A has a decreasing viscosity as the shear rate increases and then in a second range of shear rates in zone B the viscosity increases abruptly. As a second example of a response of a diluted shear thickening fluid, the first range of shear rates in zone A extends to a higher level of shear rates with the decreasing viscosity and then in the still higher second range of shear rates in zone B the viscosity increases abruptly similar to that of the shear thickening include.

[0047] The shear thickening fluid includes particles within a solvent. Examples of particles of the shear thickening fluid include oxides, calcium carbonate, synthetically occurring minerals, naturally occurring minerals, polymers, or a mixture thereof. Further examples of the particles of the shear thickening fluid include SiO₂, polystyrene, or polymethylmethacrylate.

[0048] The particles are suspended in a solvent. Example components of the solvent include water, a salt, a surfactant, and a polymer. Further example components of the solvent include ethylene glycol, polyethylene glycol, ethanol, silicon oils, phenyltrimethicone or a mixture thereof. Example particle diameters range from less than 100 μm to less than 1 millimeter. In an instance, the shear thickening fluid is made of silica particles suspended in polyethylene glycol at a volume fraction of approximately 0.57 with the silica particles having an average particle diameter of approximately 446 nm. As a result, the shear thickening fluid exhibits a shear thickening transition at a shear rate of approximately 102-103 s⁻¹.

[0049] A volume fraction of particles dispersed within the solvent distinguishes the viscosity versus shear rate of different shear thickening fluids. The viscosity of the STF changes in response to the applied shear stress. At rest and under weak applied shear stress, a STF may have a fairly constant or even slightly decreasing viscosity because the random distribution of particles causes the particles to frequently collide. However, as a greater shear stress is applied so that the shear rate increases, the particles flow in a more streamlined manner. However, as an even greater shear stress is applied so that the shear rate increases further, a hydrodynamic coupling between the particles may overcome the interparticle forces responsible for Brownian motion. The particles may be driven closer together, and the microstructure of the colloidal dispersion may change, so that particles cluster together in hydroclusters.

[0050] The viscosity curve of the STF can be fine-tuned through changes in the characteristics of the particles suspended in the solvent. For example, the particles shape, surface chemistry, ionic strength, and size affect the various interparticle forces involved, as does the properties of the solvent. However, in general, hydrodynamic forces dominate at a high shear stress, which also makes the addition of a polymer attached to the particle surface effective in limiting clumping in hydroclusters. Various factors influence this clumping behavior, including, fluid slip, adsorbed ions, surfactants, polymers, surface roughness, graft density (e.g., of a grafted polymer), molecular weight, and solvent, so that the onset of shear thickening can be modified. In general, the onset of shear thickening can be slowed by the introduction of techniques to prevent the clumping of particles. For example, influencing the STF with emissions from an emitter in proximal location to the chamber.

[0051] FIG. 1C is a graph of piston velocity vs. force applied to the piston for an aspect of an embodiment of a mechanical and computing system that includes a chamber, a shear thickening fluid, and a piston that moves through the chamber applying forces on the shear thickening fluid. The shear thickening fluid includes a non-Newtonian fluid since the relationship between shear rate and viscosity is nonlinear.

[0052] An example curve for a shear thickening fluid indicates that as more force is applied to the piston in zone A, a higher piston velocity is realized until the corresponding transition to zone B occurs where the shear threshold affect takes hold and the viscosity abruptly increases significantly. When the viscosity increases abruptly, the piston velocity slows back down and may even stop.

[0053] Another example curve for a diluted shear thickening fluid indicates that as more force is

applied to the piston in zone A, an even higher piston velocity is realized until the corresponding transition to zone B occurs where the shear threshold affect takes hold and the viscosity abruptly increases significantly. When the viscosity increases abruptly, the piston velocity slows back down and may even stop.

[0054] FIG. 2A is a schematic block diagram of an embodiment of the computing entity (e.g., **20-1** through **20-N**; and **22**) of the mechanical and computing system of FIG. 1. The computing entity includes one or more computing devices **100-1** through **100-N**. A computing device is any electronic device that communicates data, processes data, represents data (e.g., user interface) and/or stores data.

[0055] Computing devices include portable computing devices and fixed computing devices. Examples of portable computing devices include an embedded controller, a smart sensor, a social networking device, a gaming device, a smart phone, a laptop computer, a tablet computer, a video game controller, and/or any other portable device that includes a computing core. Examples of fixed computing devices includes a personal computer, a computer server, a cable set-top box, a fixed display device, an appliance, and industrial controller, a video game counsel, a home entertainment controller, a critical infrastructure controller, and/or any type of home, office or cloud computing equipment that includes a computing core.

[0056] FIG. 2B is a schematic block diagram of an embodiment of a computing device (e.g., **100-1** through **100-N**) of the computing entity of FIG. 2A that includes one or more computing cores **52-1** through **52-N**, a memory module **102**, a human interface module **18**, an environment sensor module **14**, and an input/output (I/O) module **104**. In alternative embodiments, the human interface module **18**, the environment sensor module **14**, the I/O module **104**, and the memory module **102** may be standalone (e.g., external to the computing device). An embodiment of the computing device is discussed in greater detail with reference to FIG. 3.

[0057] FIG. 3 is a schematic block diagram of another embodiment of the computing device **100-1** of the mechanical and computing system of FIG. 1 that includes the human interface module **18**, the environment sensor module **14**, the computing core **52-1**, the memory module **102**, and the I/O module **104**. The human interface module **18** includes one or more visual output devices **74** (e.g., video graphics display, 3-D viewer, touchscreen, LED, etc.), one or more visual input devices **80** (e.g., a still image camera, a video camera, a 3-D video camera, photocell, etc.), and one or more audio output devices **78** (e.g., speaker(s), headphone jack, a motor, etc.). The human interface module **18** further includes one or more user input devices **76** (e.g., keypad, keyboard, touchscreen, voice to text, a push button, a microphone, a card reader, a door position switch, a biometric input device, etc.) and one or more motion output devices **106** (e.g., servos, motors, lifts, pumps, actuators, anything to get real-world objects to move).

[0058] The computing core **52-1** includes a video graphics module **54**, one or more processing modules **50-1** through **50-N**, a memory controller **56**, one or more main memories **58-1** through **58-N** (e.g., RAM), one or more input/output (I/O) device interface modules **62**, an input/output (I/O) controller **60**, and a peripheral interface **64**. A processing module is as defined at the end of the detailed description.

[0059] The memory module **102** includes a memory interface module **70** and one or more memory devices, including flash memory devices **92**, hard drive (HD) memory **94**, solid state (SS) memory **96**, and cloud memory **98**. The cloud memory **98** includes an on-line storage system and an on-line backup system.

[0060] The I/O module **104** includes a network interface module **72**, a peripheral device interface module **68**, and a universal serial bus (USB) interface module **66**. Each of the I/O device interface module **62**, the peripheral interface **64**, the memory interface module **70**, the network interface module **72**, the peripheral device interface module **68**, and the USB interface modules **66** includes a combination of hardware (e.g., connectors, wiring, etc.) and operational instructions stored on memory (e.g., driver software) that are executed by one or more of the processing modules **50-1**

through **50-N** and/or a processing circuit within the particular module.

[0061] The I/O module **104** further includes one or more wireless location modems **84** (e.g., global positioning satellite (GPS), Wi-Fi, angle of arrival, time difference of arrival, signal strength, dedicated wireless location, etc.) and one or more wireless communication modems **86** (e.g., a cellular network transceiver, a wireless data network transceiver, a Wi-Fi transceiver, a Bluetooth transceiver, a 315 MHz transceiver, a zig bee transceiver, a 60 GHz transceiver, etc.). The I/O module **104** further includes a telco interface **108** (e.g., to interface to a public switched telephone network), a wired local area network (LAN) **88** (e.g., optical, electrical), and a wired wide area network (WAN) **90** (e.g., optical, electrical). The I/O module **104** further includes one or more peripheral devices (e.g., peripheral devices **1-P**) and one or more universal serial bus (USB) devices (USB devices **1-U**). In other embodiments, the computing device **100-1** may include more or less devices and modules than shown in this example embodiment.

[0062] FIG. **4** is a schematic block diagram of an embodiment of the environment sensor module **14** of the computing device of FIG. **2B** that includes a sensor interface module **120** to output environment sensor information **150** based on information communicated with a set of sensors. The set of sensors includes a visual sensor **122** (e.g., to the camera, 3-D camera, 360° view camera, a camera array, an optical spectrometer, etc.) and an audio sensor **124** (e.g., a microphone, a microphone array). The set of sensors further includes a motion sensor **126** (e.g., a solid-state Gyro, a vibration detector, a laser motion detector) and a position sensor **128** (e.g., a Hall effect sensor, an image detector, a GPS receiver, a radar system).

[0063] The set of sensors further includes a scanning sensor **130** (e.g., CAT scan, MRI, x-ray, ultrasound, radio scatter, particle detector, laser measure, further radar) and a temperature sensor **132** (e.g., thermometer, thermal coupler). The set of sensors further includes a humidity sensor **134** (resistance based, capacitance based) and an altitude sensor **136** (e.g., pressure based, GPS-based, laser-based).

[0064] The set of sensors further includes a biosensor **138** (e.g., enzyme, microbial) and a chemical sensor **140** (e.g., mass spectrometer, gas, polymer). The set of sensors further includes a magnetic sensor **142** (e.g., Hall effect, piezo electric, coil, magnetic tunnel junction) and any generic sensor **144** (e.g., including a hybrid combination of two or more of the other sensors).

[0065] FIGS. **5A-5D** are schematic block diagrams of another embodiment of a mechanical and computing system illustrating an example of determining operational aspects. The mechanical and computing system includes the head unit **10-1** of FIG. **1**, the object **12-1** of FIG. **1**, and the computing entity **20-1** of FIG. **1**.

[0066] In particular, the head unit **10-1** for controlling motion of the object **12-1** includes a chamber **16** filled at least in part with a shear thickening fluid (STF) **42**, where the STF includes a multitude of magnetic nanoparticles **170**. The head unit **10-1** further includes a piston **36** housed at least partially radially within the chamber **16**. The piston **36** is configured to exert pressure against the shear thickening fluid **42** in response to movement of the piston **36** from a force applied to the piston **36** from the object **12-1**.

[0067] The movement of the piston **36** includes one of traveling through the chamber **16** in an inward direction or traveling through the chamber **16** in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates. The head unit **10-1** further includes a set of magnetic field sensors **116-1-1** and **116-1-2** positioned proximal to the chamber **16**. For instance, the magnetic field sensors are implemented utilizing Hall effect sensors.

[0068] FIG. **5A** illustrates an example of operation of a method for the determining the operational aspects. A first step of the example of operation includes the computing entity **20-1** interpreting magnetic response **180-1-2** from the set of magnetic field sensors (e.g., in response to varying fields from the magnetic nanoparticles **170**) to produce a piston velocity and position. The set of magnetic field sensors are positioned proximal to the head unit **10-1** for controlling motion of the

object **12-1**, where the head unit includes the chamber filled at least in part with a shear thickening fluid (STF). The STF includes a multitude of magnetic nanoparticles. The piston is housed at least partially radially within the chamber and the piston is configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston from the object **12-1**. The movement of the piston includes one of traveling through the chamber in an inward direction or traveling through the chamber in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0069] As an example of interpreting the magnetic response **180-1-2**, the computing entity **20-1** compares the magnetic response **180-1-2** to previous measurements of magnetic fields versus piston velocity and position to produce the piston velocity **182** and piston position **184**. As another example of the interpreting the magnetic response **180-1-2**, the computing entity **20-1** extracts the piston velocity **182** and the piston position **184** directly from the magnetic response **180-1-2** when the sensor **116-1-2** generates the velocity and piston position directly.

[0070] FIG. 5B further illustrates the example of operation of the method for the determining the operational aspects. A second step of the example of operation includes the computing entity **20-1** interpreting magnetic response **180-1-1** from the set of magnetic field sensors to produce updated piston velocity and position as previously discussed. For example, the computing entity **20-1** interprets the magnetic response **180-1-1** to determine the updated piston velocity **182** and piston position **184**. For instance, the computing entity **20-1** determines that the position of the piston is further inward within the chamber **16** and moving inward with a higher velocity as compared to the previous interpretation step.

[0071] FIG. 5C further illustrates the example of operation of the method for the determining the operational aspects. A third step of the example of operation includes the computing entity **20-1** determining a shear force **186** based on the updated piston velocity **182** and piston position **184**. For example, the computing entity **20-1** compares the updated velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**. As another example, the computing entity **20-1** receives the shear force **186** from at least one of the set of sensors when at least one sensor provides the shear force **186** directly.

[0072] FIG. 5D further illustrates the example of operation of the method for the determining the operational aspects. A fourth step of the example of operation includes the computing entity **20-1** determining whether a shear threshold has been obtained based on the shear force **186**. The shear threshold is associated with the increasing viscosity in response to the second range of shear rates. For example, the computing entity **20-1** compares the shear force **186** to data associated with the viscosity versus shear rate curve and indicates via a shear threshold indicator **188** that the shear threshold has been obtained when the shear force **186** compares favorably to the data associated with the viscosity versus shear rate curve for the shear threshold effect. As another example, the computing entity **20-1** interprets the piston velocity **182** over time to produce acceleration and indicates the shear threshold via the shear threshold indicator **188** when detecting a sudden deceleration.

[0073] The method described above in conjunction with a processing module of any computing entity of the mechanical and computing system of FIG. 1 can alternatively be performed by other modules of the system of FIG. 1 or by other devices. In addition, at least one memory section that is non-transitory (e.g., a non-transitory computer readable storage medium, a non-transitory computer readable memory organized into a first memory element, a second memory element, a third memory element, a fourth element section, a fifth memory element, a sixth memory element, etc.) that stores operational instructions can, when executed by one or more processing modules of the one or more computing entities of the computing system **10**, cause one or more computing devices of the mechanical and computing system of FIG. 1 to perform any or all of the method steps described above.

[0074] FIGS. 6A-6C are schematic block diagrams of another embodiment of a mechanical and computing system illustrating an example of controlling operational aspects. The mechanical and computing system includes the head unit **10-1** of FIG. 1, the object **12-1** of FIG. 1, and the computing entity **20-1** of FIG. 1.

[0075] In particular, the head unit **10-1** for controlling motion of the object **12-1** includes the chamber **16** filled at least in part with the shear thickening fluid (STF) **42**, where the STF includes a multitude of magnetic nanoparticles **170**. The piston is housed at least partially radially within the chamber **16**. The piston **36** is configured to exert pressure against the shear thickening fluid in response to movement of the piston **36** from a force applied to the piston **36** via the plunger **28** from the object **12-1**.

[0076] The movement of the piston **36** includes one of traveling through the chamber **16** in an inward direction or traveling through the chamber **16** in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0077] The head unit **10-1** further includes a set of magnetic field sensors positioned proximal to the chamber **16** and a set of magnetic field emitters positioned proximal to the chamber **16**. The set of magnetic field sensors provide a magnetic response from the multitude of magnetic nanoparticles. The set of magnetic field emitters provide a magnetic activation to the multitude of magnetic nanoparticles which in turn affects the STF. For example, sensors **116-1-1** and **116-1-2** and emitters **114-1-1** and **114-1-2**, where the sensors and emitters sense and emit magnetic waves respectively to interact with the magnetic nanoparticles **170**.

[0078] FIG. 6A illustrates an example of operation of a method for the controlling the operational aspects. A first step of the example of operation includes the computing entity **20-1** interpreting magnetic response **180-1-1** and **180-1-2** from the set of magnetic field sensors (e.g., in response to varying fields from the magnetic nanoparticles **170**) to produce a piston velocity and piston position. The set of magnetic field sensors are positioned proximal to the head unit **10-1** for controlling motion of the object **12-1**, where the head unit includes the chamber filled at least in part with a shear thickening fluid (STF).

[0079] The STF includes a multitude of magnetic nanoparticles. The piston is housed at least partially radially within the chamber and the piston is configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston from the object **12-1**. The movement of the piston includes one of traveling through the chamber in an inward direction or traveling through the chamber in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0080] The interpreting the magnetic response from the set of magnetic field sensors to produce the piston velocity and the piston position of the piston includes a series of sub-steps. A first sub-step includes inputting, from one or more magnetic field sensors of the set of magnetic field sensors, a set of magnetic field signals over a time range. For example, the computing entity **20-1** inputs a magnetic field signal from sensor **116-1-1** during a first timeframe of the time range and another magnetic field signal from sensor **116-1-2** during a second timeframe of the time range.

[0081] A second sub-step includes determining the magnetic response of the set of magnetic field sensors based on the set of magnetic field signals. For example, the computing entity **20-1** interprets the magnetic field signals based on a type of magnetic sensor to produce magnetic responses **180-1-1** and **180-1-2**.

[0082] A third sub-step includes determining the piston velocity based on the magnetic response of the set of magnetic field sensors over the time range. For example, the computing entity **20-1** calculates velocity based on changes in the magnetic responses over the time range.

[0083] A fourth sub-step includes determining the piston position based on the piston velocity and a real-time reference. For example, the computing entity **20-1** calculates the piston position based on

time and the piston velocity as the piston moves through the chamber.

[0084] As another example of interpreting the magnetic response **180-1-2**, the computing entity **20-1** compares the magnetic response **180-1-2** to previous measurements of magnetic fields versus piston velocity and piston position to produce the piston velocity **182** and piston position **184**. As a still further example of the interpreting the magnetic response **180-1-2**, the computing entity **20-1** extracts the piston velocity **182** and the piston position **184** directly from the magnetic response **180-1-2** when the sensor **116-1-2** generates the piston velocity and piston position directly.

[0085] A second step of the example of operation includes the computing entity **20-1** determining a shear force **186** based on the piston velocity **182** and piston position **184**. The determining the shear force based on the piston velocity and the piston position includes one approach of a variety of approaches. A first approach includes extracting the shear force directly from the magnetic response when one or more magnetic field sensors of the set of magnetic field sensors outputs a shear force encoded signal. For example, the computing entity **20-1** extracts the shear force **186** directly from the magnetic responses **180-1-1** and **180-1-2**. In an instance, the shear force **186** reveals the piston velocity versus force applied to the piston curve as illustrated in FIG. **6A**, where at a current time of interpreting the magnetic response, the force and piston velocity are at a point **X1**.

[0086] A second approach includes determining the shear force utilizing the piston velocity and stored data for piston velocity versus shear force for the STF. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**.

[0087] A third approach includes determining the shear force utilizing the piston position and stored data for piston position versus shear force for the STF within the chamber. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**.

[0088] FIG. **6B** further illustrates the example of operation of the method for the controlling the operational aspects. A third step of the example of operation includes the computing entity **20-1** determining a desired response **188** for the STF based on one or more of the shear force **186** and the piston velocity **182** and the piston position **184**. The desired response **188** includes continuing to follow a nominal response curve associated with the STF without modifying the functioning of the STF. The desired response **188** further includes modifying the function of the STF to further slow down the object **12-1** or to allow the object **12-1** to speed up at a velocity associated with the nominal response.

[0089] The determining the desired response for the STF based on one or more of the shear force, the piston velocity, and piston position includes one or more approaches. A first approach includes interpreting a request associated with modifying one or more of object velocity and object position. For example, the computing entity **20-1** interprets a request from another computing entity to update the desired response for the STF to increase viscosity to slow down the object **12-1**.

[0090] A second approach includes interpreting guidance from a chamber database. For example, the computing entity **20-1** interprets data from the chamber database **34** of FIG. **1A** to identify an updated response for the STF. For instance, the response for the STF is updated to decrease viscosity when historical information in the chamber database **34** indicates that a decrease in viscosity is desired based on a current piston position and current shear force.

[0091] A third approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the piston position is greater than a maximum piston position threshold level. A fourth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the piston position is less than a minimum piston position threshold level.

[0092] A fifth approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the piston velocity is greater than a

maximum piston velocity threshold level. A sixth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the piston velocity is less than a minimum piston velocity threshold level.

[0093] A seventh approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the shear force is less than a minimum shear force threshold level. An eighth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the shear force is greater than a maximum shear force threshold level.

[0094] A ninth approach includes detecting an environmental condition warranting a change in viscosity of the STF. For example, the computing entity **20-1** determines to change the viscosity of the STF when a triggering of a vehicular airbag sensor is detected. As another example, the computing entity **20-1** determines to change the viscosity of the STF when detecting an earthquake. As yet another example, the computing entity **20-1** determines to change the viscosity of the STF when detecting a proximity warning (e.g., of a certain collision).

[0095] Having determined the desired response **188** for the STF, a fourth step of the example method of operation includes the computing entity **20-1** generating a magnetic activation based on the desired response for the STF, where the magnetic activation is output to the set of magnetic field emitters positioned proximal to the chamber **16**. The generating the magnetic activation based on the desired response for the STF includes one or more approaches. A first approach includes determining magnetic output values for the magnetic activation based on a difference between actual viscosity of the STF and a desired viscosity of the STF. For example, the computing entity **20-1** determines the magnetic activation to affect the STF such that the viscosity is raised to lead to an abrupt slow down of the piston through the STF.

[0096] A second approach includes determining the magnetic activation based on the desired response for the STF and utilizing a magnetic activation table for magnetic output values versus the desired viscosity of the STF. For example, the computing entity **20-1** performs a lookup in a magnetic activation table for magnetic output values versus desired viscosity increases.

[0097] A third approach includes receiving the magnetic activation from another computing device. Having determined the magnetic activation, in a fourth approach, the computing entity **20-1** outputs the magnetic activation to the set of magnetic field emitters. For instance, the computing entity **20-1** outputs the magnetic activation **181-1-1** and **181-1-2** to the emitters **114-1-1** and **114-1-2** respectively to affect the viscosity of the STF **42**.

[0098] FIG. **6C** further illustrates the example of operation of the method for the controlling the operational aspects where, having generated the magnetic activation, the computing entity **20-1** determines an error level **190** from the desired response for the STF **42**. For example, the computing entity **20-1** re-measures the magnetic response to determine one or more of piston velocity **182**, piston position **184**, and shear force **186**. Having determined velocity and position, the computing entity **20-1** determines actual response at a time **X2** and compares the piston velocity versus force applied to the piston to the desired response curve. The computing entity **20-1** determines the error level **190** based on the comparison.

[0099] Having determined the error level, a sixth step of the example of operation of the method for the controlling the operational aspects includes the computing entity **20-1** generating an updated magnetic activation based on the error level and the desired response. The error level is at least one of substantially zero (e.g., the actual response is on top of the desired response), a positive error level (e.g., when the actual response includes a piston velocity that is too high for the force applied to the piston), and a negative error level (e.g., when the actual response includes a piston velocity that is too low for the force applied to the piston). In an example of generating the updated magnetic activation, the computing entity **20-1** determines that the error level **190** is a positive error level, determines the updated magnetic activation to further increase the viscosity of the STF **42**, and outputs magnetic activation **181-1-1** and **181-1-2** to the emitters **114-1-1** and **114-1-2**

respectively to facilitate slowing down the piston velocity back to the desired response curve. [0100] The method described above in conjunction with a processing module of any computing entity of the mechanical and computing system of FIG. 1 can alternatively be performed by other modules of the system of FIG. 1 or by other devices. In addition, at least one memory section that is non-transitory (e.g., a non-transitory computer readable storage medium, a non-transitory computer readable memory organized into a first memory element, a second memory element, a third memory element, a fourth element section, a fifth memory element, a sixth memory element, etc.) that stores operational instructions can, when executed by one or more processing modules of the one or more computing entities of the computing system 10, cause one or more computing devices of the mechanical and computing system of FIG. 1 to perform any or all of the method steps described above.

[0101] FIGS. 7A-7D are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of determining operational aspects. The mechanical and computing system includes the head unit 10-1 of FIG. 1, the object 12-1 of FIG. 1, and the computing entity 20-1 of FIG. 1.

[0102] In particular, the head unit 10-1 for controlling motion of the object 12-1 includes a chamber 16 filled at least in part with a shear thickening fluid (STF) 42, where the STF includes a multitude of reflective nanoparticles 200. The head unit 10-1 further includes a piston 36 housed at least partially radially within the chamber 16. The piston 36 is configured to exert pressure against the shear thickening fluid 42 in response to movement of the piston 36 from a force applied to the piston 36 from the object 12-1.

[0103] The movement of the piston 36 includes one of traveling through the chamber 16 in an inward direction or traveling through the chamber 16 in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates. The head unit 10-1 further includes a set of optical sensors 116-1-1 and 116-1-2 positioned proximal to the chamber 16. For instance, the optical sensors are implemented utilizing image sensors (e.g., cameras).

[0104] FIG. 7A illustrates an example of operation of a method for the determining the operational aspects. A first step of the example of operation includes the computing entity 20-1 interpreting an optical response from the set of optical sensors (e.g., in response to varying light patterns from the reflective nanoparticles 200) to produce a piston velocity and position. The set of optical sensors are positioned proximal to the head unit 10-1 for controlling motion of the object 12-1, where the head unit includes the chamber filled at least in part with a shear thickening fluid (STF). The STF includes the multitude of reflective nanoparticles. The piston is housed at least partially radially within the chamber and the piston is configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston from the object 12-1. The movement of the piston includes one of traveling through the chamber in an inward direction or traveling through the chamber in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0105] As an example of interpreting the optical response, the computing entity 20-1 compares the optical response 202-1-2 to previous measurements of light fields versus piston velocity and position to produce the piston velocity 182 and piston position 184. As another example of the interpreting the optical response 202-1-2, the computing entity 20-1 extracts the piston velocity 182 and the piston position 184 directly from the optical response 202-1-2 when the sensor 116-1-2 generates the velocity and piston position directly.

[0106] FIG. 7B further illustrates the example of operation of the method for the determining the operational aspects. A second step of the example of operation includes the computing entity 20-1 interpreting optical response 202-1-1 from the set of optical sensors to produce updated piston velocity and position as previously discussed. For example, the computing entity 20-1 interprets the

optical response **202-1-1** to determine the updated piston velocity **182** and piston position **184**. For instance, the computing entity **20-1** determines that the position of the piston is further inward within the chamber **16** and moving inward with a higher velocity as compared to the previous interpretation step.

[0107] FIG. 7C further illustrates the example of operation of the method for the determining the operational aspects. A third step of the example of operation includes the computing entity **20-1** determining a shear force **186** based on the updated piston velocity **182** and piston position **184**. For example, the computing entity **20-1** compares the updated velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**. As another example, the computing entity **20-1** receives the shear force **186** from at least one of the set of sensors when at least one sensor provides the shear force **186** directly.

[0108] FIG. 7D further illustrates the example of operation of the method for the determining the operational aspects. A fourth step of the example of operation includes the computing entity **20-1** determining whether a shear threshold has been obtained based on the shear force **186**. The shear threshold is associated with the increasing viscosity in response to the second range of shear rates. For example, the computing entity **20-1** compares the shear force **186** to data associated with the viscosity versus shear rate curve and indicates via a shear threshold indicator **188** that the shear threshold has been obtained when the shear force **186** compares favorably to the data associated with the viscosity versus shear rate curve for the shear threshold effect. As another example, the computing entity **20-1** interprets the piston velocity **182** over time to produce acceleration and indicates the shear threshold via the shear threshold indicator **188** when detecting a sudden deceleration.

[0109] The method described above in conjunction with a processing module of any computing entity of the mechanical and computing system of FIG. 1 can alternatively be performed by other modules of the system of FIG. 1 or by other devices. In addition, at least one memory section that is non-transitory (e.g., a non-transitory computer readable storage medium, a non-transitory computer readable memory organized into a first memory element, a second memory element, a third memory element, a fourth element section, a fifth memory element, a sixth memory element, etc.) that stores operational instructions can, when executed by one or more processing modules of the one or more computing entities of the computing system **10**, cause one or more computing devices of the mechanical and computing system of FIG. 1 to perform any or all of the method steps described above.

[0110] FIGS. 8A-8C are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects. The mechanical and computing system includes the head unit **10-1** of FIG. 1, the object **12-1** of FIG. 1, and the computing entity **20-1** of FIG. 1.

[0111] In particular, the head unit **10-1** for controlling motion of the object **12-1** includes the chamber **16** filled at least in part with the shear thickening fluid (STF) **42**, where the STF includes a multitude of piezoelectric nanoparticles **210**. The piston is housed at least partially radially within the chamber **16**. The piston **36** is configured to exert pressure against the shear thickening fluid in response to movement of the piston **36** from a force applied to the piston **36** via the plunger **28** from the object **12-1**.

[0112] The movement of the piston **36** includes one of traveling through the chamber **16** in an inward direction or traveling through the chamber **16** in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0113] The head unit **10-1** further includes a set of electric field sensors positioned proximal to the chamber **16** and a set of electric field emitters positioned proximal to the chamber **16**. For example, sensors **116-1-1** and **116-1-2** and emitters **114-1-1** and **114-1-2**, where the sensors and emitters sense and emit electric waves respectively to interact with the piezoelectric nanoparticles **210**.

[0114] FIG. 8A illustrates an example of operation of a method for the controlling the operational aspects. A first step of the example of operation includes the computing entity **20-1** interpreting electric response **212-1-1** and **212-1-2** from the set of piezoelectric nanoparticles **210** (e.g., in response to varying fields from the piezoelectric nanoparticles **210**) to produce a piston velocity and position. The set of electric field sensors are positioned proximal to the head unit **10-1** for controlling motion of the object **12-1**, where the head unit includes the chamber filled at least in part with a shear thickening fluid (STF). The STF includes the multitude of piezoelectric nanoparticles **210**. The piston is housed at least partially radially within the chamber and the piston is configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston from the object **12-1**. The movement of the piston includes one of traveling through the chamber in an inward direction or traveling through the chamber in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0115] As an example of interpreting the electric response **212-1-1** and **212-1-2**, the computing entity **20-1** compares the electric response **212-1-1** and **212-1-2** to previous measurements of electric fields versus piston velocity and position to produce the piston velocity **182** and piston position **184**. As another example of the interpreting the electric response **212-1-1** and **212-1-2**, the computing entity **20-1** extracts the piston velocity **182** and the piston position **184** directly from the electric response **212-1-1** and **212-1-2** when the sensors **116-1-1** and **116-1-2** generate the velocity and piston position directly.

[0116] A second step of the example of operation includes the computing entity **20-1** determining a shear force **186** based on the piston velocity **182** and piston position **184**. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**. As another example, the computing entity **20-1** receives the shear force **186** from at least one of the set of sensors when at least one sensor provides the shear force **186** directly. In an instance, the shear force **186** reveals the piston velocity versus force applied to the piston curve as illustrated in FIG. 8A, where at a current time of interpreting the electric response, the force and piston velocity are at a point X1.

[0117] FIG. 8B further illustrates the example of operation of the method for the controlling the operational aspects. A third step of the example of operation includes the computing entity **20-1** determining a desired response **188** for the STF based on one or more of the shear force **186** and the piston velocity **182** and the piston position **184**. The desired response **188** includes continuing to follow a nominal response curve associated with the STF without modifying the functioning of the STF. The desired response **188** further includes modifying the function of the STF to further slow down the object **12-1** or to allow the object **12-1** to speed up at a velocity associated with the nominal response.

[0118] The determining the desired response **188** includes one or more of interpreting a request, interpreting guidance from the chamber database **34**, detecting that the piston velocity is greater than a maximum piston velocity threshold level (e.g., too fast), detecting that the piston velocity is less than a minimum piston velocity threshold level (e.g., too slow), and detecting an environmental condition warranting changing the viscosity (e.g., a triggering of a vehicular airbag sensor, detection of an earthquake, a proximity warning, etc.). For instance, the computing entity **20-1** determines that the desired response **188** to slow down the object **12-1** is warranted based on reaching a maximum piston velocity threshold level for object **12-1**.

[0119] Having determined the desired response **188** for the STF, a fourth step of the example method of operation includes the computing entity **20-1** generating an electric activation based on the desired response for the STF, where the electric activation is output to a set of electric field emitters positioned proximal to the chamber **16**. The generating of the electric activation includes one or more of performing a lookup in an electric activation table for electric field output values versus desired viscosity increases, dynamically calculating the electric field output values based on

a gap in viscosity levels, and receiving the electric activation from another computing entity. For example, the computing entity **20-1** determines the electric activation to affect the STF such that the viscosity is raised to lead to an abrupt slow down of the piston through the STF. Having determined the electric activation, the computing entity **20-1** outputs electric activation **214-1-1** and **214-1-2** to the emitters **114-1-1** and **114-1-2** respectively to affect the viscosity of the STF **42**. [0120] FIG. **8C** further illustrates the example of operation of the method for the controlling the operational aspects where, having generated the electric activation, the computing entity **20-1** determines an error level **190** from the desired response for the STF **42**. For example, the computing entity **20-1** re-measures the electric response to determine one or more of piston velocity **182**, piston position **184**, and shear force **186**. Having determined velocity and position, the computing entity **20-1** determines actual response at a time **X2** and compares the piston velocity versus force applied to the piston to the desired response curve. The computing entity **20-1** determines the error level **190** based on the comparison.

[0121] Having determined the error level, a sixth step of the example of operation of the method for the controlling the operational aspects includes the computing entity **20-1** generating an updated electric activation based on the error level and the desired response. The error level is at least one of substantially zero (e.g., the actual response is on top of the desired response), a positive error level (e.g., when the actual response includes a piston velocity that is too high for the force applied to the piston), and a negative error level (e.g., when the actual response includes a piston velocity that is too low for the force applied to the piston). In an example of generating the updated electric activation, the computing entity **20-1** determines that the error level **190** is a positive error level, determines the updated electric activation to further increase the viscosity of the STF **42**, and outputs electric activation **214-1-1** and **214-1-2** to the emitters **114-1-1** and **114-1-2** respectively to facilitate slowing down the piston velocity back to the desired response curve.

[0122] The method described above in conjunction with a processing module of any computing entity of the mechanical and computing system of FIG. **1** can alternatively be performed by other modules of the system of FIG. **1** or by other devices. In addition, at least one memory section that is non-transitory (e.g., a non-transitory computer readable storage medium, a non-transitory computer readable memory organized into a first memory element, a second memory element, a third memory element, a fourth element section, a fifth memory element, a sixth memory element, etc.) that stores operational instructions can, when executed by one or more processing modules of the one or more computing entities of the computing system **10**, cause one or more computing devices of the mechanical and computing system of FIG. **1** to perform any or all of the method steps described above.

[0123] FIGS. **9A-9C** are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects. The mechanical and computing system includes the head unit **10-1** of FIG. **1**, the object **12-1** of FIG. **1**, and the computing entity **20-1** of FIG. **1**.

[0124] In particular, the head unit **10-1** for controlling motion of the object **12-1** includes the chamber **16** filled at least in part with the shear thickening fluid (STF) **42**. The piston is housed at least partially radially within the chamber **16**. The piston **36** is configured to exert pressure against the shear thickening fluid in response to movement of the piston **36** from a force applied to the piston **36** via the plunger **28** from the object **12-1**.

[0125] The movement of the piston **36** includes one of traveling through the chamber **16** in an inward direction or traveling through the chamber **16** in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0126] The head unit **10-1** further includes a set of audio sensors positioned proximal to the chamber **16** and a set of audio emitters positioned proximal to the chamber **16**. For example, sensors **116-1-1** and **116-1-2** and emitters **114-1-1** and **114-1-2**, where the sensors and emitters

sense and emit acoustic waves respectively to interact with the STF **42**. For instance, sensor **116-1-1** is implemented utilizing a microphone and emitter **114-1-1** is implemented utilizing an ultrasonic transducer.

[0127] FIG. **9A** illustrates an example of operation of a method for the controlling the operational aspects. A first step of the example of operation includes the computing entity **20-1** interpreting audio responses **222-1-1** and **222-1-2** from the STF **42** (e.g., in response to varying acoustic responsiveness of the particles of the STF) to produce a piston velocity and position. The set of audio sensors are positioned proximal to the head unit **10-1** for controlling motion of the object **12-1**, where the head unit includes the chamber filled at least in part with a shear thickening fluid (STF). In another embodiment, the STF is mixed with acoustic nanoparticles to enhance the transmission of acoustic waves through the STF. The piston is housed at least partially radially within the chamber and the piston is configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston from the object **12-1**. The movement of the piston includes one of traveling through the chamber in an inward direction or traveling through the chamber in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0128] As an example of interpreting the audio response **222-1-1** and **222-1-2**, the computing entity **20-1** compares the audio response **222-1-1** and **222-1-2** to previous measurements of audio waves versus piston velocity and position to produce the piston velocity **182** and piston position **184**. As another example of the interpreting the audio response **222-1-1** and **222-1-2**, the computing entity **20-1** extracts the piston velocity **182** and the piston position **184** directly from the audio response **222-1-1** and **222-1-2** when the sensors **116-1-1** and **116-1-2** generate the velocity and piston position directly.

[0129] A second step of the example of operation includes the computing entity **20-1** determining a shear force **186** based on the piston velocity **182** and piston position **184**. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**. As another example, the computing entity **20-1** receives the shear force **186** from at least one of the set of sensors when at least one sensor provides the shear force **186** directly. In an instance, the shear force **186** reveals the piston velocity versus force applied to the piston curve as illustrated in FIG. **9A**, where at a current time of interpreting the audio response, the force and piston velocity are at a point **X1**.

[0130] FIG. **9B** further illustrates the example of operation of the method for the controlling the operational aspects. A third step of the example of operation includes the computing entity **20-1** determining a desired response **188** for the STF based on one or more of the shear force **186** and the piston velocity **182** and the piston position **184**. The desired response **188** includes continuing to follow a nominal response curve associated with the STF without modifying the functioning of the STF. The desired response **188** further includes modifying the function of the STF to further slow down the object **12-1** or to allow the object **12-1** to speed up at a velocity associated with the nominal response.

[0131] The determining the desired response **188** includes one or more of interpreting a request, interpreting guidance from the chamber database **34**, detecting that the piston velocity is greater than a maximum piston velocity threshold level (e.g., too fast), detecting that the piston velocity is less than a minimum piston velocity threshold level (e.g., too slow), and detecting an environmental condition warranting changing the viscosity (e.g., a triggering of a vehicular airbag sensor, detection of an earthquake, a proximity warning, etc.). For instance, the computing entity **20-1** determines that the desired response **188** to slow down the object **12-1** is warranted based on reaching a maximum piston velocity threshold level for object **12-1**.

[0132] Having determined the desired response **188** for the STF, a fourth step of the example method of operation includes the computing entity **20-1** generating an audio activation based on the

desired response for the STF, where the audio activation is output to the set of audio emitters positioned proximal to the chamber **16**. The generating of the audio activation includes one or more of performing a lookup in an audio activation table for audio wave output values versus desired viscosity increases, dynamically calculating the audio wave output values based on a gap in viscosity levels, and receiving the audio activation from another computing entity. For example, the computing entity **20-1** determines the audio activation to affect the STF such that the viscosity is raised to lead to an abrupt slow down of the piston through the STF. Having determined the audio activation, the computing entity **20-1** outputs audio activation **224-1-1** and **224-1-2** to the emitters **114-1-1** and **114-1-2** respectively to affect the viscosity of the STF **42**.

[0133] FIG. **9C** further illustrates the example of operation of the method for the controlling the operational aspects where, having generated the audio activation, the computing entity **20-1** determines an error level **190** from the desired response for the STF **42**. For example, the computing entity **20-1** re-measures the audio response to determine one or more of piston velocity **182**, piston position **184**, and shear force **186**. Having determined velocity and position, the computing entity **20-1** determines actual response at a time **X2** and compares the piston velocity versus force applied to the piston to the desired response curve. The computing entity **20-1** determines the error level **190** based on the comparison.

[0134] Having determined the error level, a sixth step of the example of operation of the method for the controlling the operational aspects includes the computing entity **20-1** generating an updated audio activation based on the error level and the desired response. The error level is at least one of substantially zero (e.g., the actual response is on top of the desired response), a positive error level (e.g., when the actual response includes a piston velocity that is too high for the force applied to the piston), and a negative error level (e.g., when the actual response includes a piston velocity that is too low for the force applied to the piston). In an example of generating the updated audio activation, the computing entity **20-1** determines that the error level **190** is a positive error level, determines the updated audio activation to further increase the viscosity of the STF **42**, and outputs audio activation **224-1-1** and **224-1-2** to the emitters **114-1-1** and **114-1-2** respectively to facilitate slowing down the piston velocity back to the desired response curve.

[0135] The method described above in conjunction with a processing module of any computing entity of the mechanical and computing system of FIG. **1** can alternatively be performed by other modules of the system of FIG. **1** or by other devices. In addition, at least one memory section that is non-transitory (e.g., a non-transitory computer readable storage medium, a non-transitory computer readable memory organized into a first memory element, a second memory element, a third memory element, a fourth element section, a fifth memory element, a sixth memory element, etc.) that stores operational instructions can, when executed by one or more processing modules of the one or more computing entities of the computing system **10**, cause one or more computing devices of the mechanical and computing system of FIG. **1** to perform any or all of the method steps described above.

[0136] FIGS. **10A-10C** are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects. The mechanical and computing system includes the head unit **10-1** of FIG. **1**, the object **12-1** of FIG. **1**, and the computing entity **20-1** of FIG. **1**.

[0137] In particular, the head unit **10-1** for controlling motion of the object **12-1** includes the chamber **16** filled at least in part with the shear thickening fluid (STF) **42**. The piston is housed at least partially radially within the chamber **16**. The piston **36** is configured to exert pressure against the shear thickening fluid in response to movement of the piston **36** from a force applied to the piston **36** via the plunger **28** from the object **12-1**.

[0138] The movement of the piston **36** includes one of traveling through the chamber **16** in an inward direction or traveling through the chamber **16** in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an

increasing viscosity in response to a second range of shear rates.

[0139] The head unit **10-1** further includes a set of fluid flow sensors (e.g., any type) positioned proximal to the chamber **16** and a set of fluid manipulation emitters (e.g., any type) positioned proximal to the chamber **16**. For example, sensors **116-1-1** and **116-1-2** and emitters **114-1-1** and **114-1-2**, where the sensors and emitters sense and emit energy respectively to interact with the STF **42**.

[0140] FIG. **10A** illustrates an example of operation of a method for the controlling the operational aspects. A first step of the example of operation includes the computing entity **20-1** interpreting fluid responses **232-1-1** and **232-1-2** from the STF **42** (e.g., in response to varying responsiveness of the particles of the STF) to produce a piston velocity and position. The set of fluid flow sensors are positioned proximal to the head unit **10-1** for controlling motion of the object **12-1**, where the head unit includes the chamber filled at least in part with the shear thickening fluid (STF) **42**. In another embodiment, the STF is mixed with nanoparticles to enhance the transmission of energy through the STF. The piston is housed at least partially radially within the chamber and the piston is configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston from the object **12-1**. The movement of the piston includes one of traveling through the chamber in an inward direction or traveling through the chamber in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0141] As an example of interpreting the fluid response **232-1-1** and **232-1-2**, the computing entity **20-1** compares the fluid response **232-1-1** and **232-1-2** to previous measurements of fluid responses versus piston velocity and position to produce the piston velocity **182** and piston position **184**. As another example of the interpreting the fluid response **232-1-1** and **232-1-2**, the computing entity **20-1** extracts the piston velocity **182** and the piston position **184** directly from the fluid response **232-1-1** and/or **232-1-2** when the sensors **116-1-1** and **116-1-2** generate the velocity and piston position directly.

[0142] A second step of the example of operation includes the computing entity **20-1** determining a shear force **186** based on the piston velocity **182** and piston position **184**. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**. As another example, the computing entity **20-1** receives the shear force **186** from at least one of the set of sensors when at least one sensor provides the shear force **186** directly. In an instance, the shear force **186** reveals the piston velocity versus force applied to the piston curve as illustrated in FIG. **10A**, where at a current time of interpreting the audio response, the force and piston velocity are at a point **Y1**. That curve further illustrates nominal responses for both positive and negative velocities corresponding to inward and outward movement of the piston.

[0143] FIG. **10B** further illustrates the example of operation of the method for the controlling the operational aspects. A third step of the example of operation includes the computing entity **20-1** determining a desired response **188** for the STF based on one or more of the shear force **186** and the piston velocity **182** and the piston position **184**. The desired response **188** includes continuing to follow a nominal response curve associated with the STF without modifying the functioning of the STF. The desired response **188** further includes modifying the function of the STF to further slow down the object **12-1** or to allow the object **12-1** to speed up at a velocity associated with the nominal response.

[0144] The determining the desired response **188** includes one or more of interpreting a request, interpreting guidance from the chamber database **34**, detecting that the piston velocity is greater than a maximum piston velocity threshold level (e.g., too fast), detecting that the piston velocity is less than a minimum piston velocity threshold level (e.g., too slow), and detecting an environmental condition warranting changing the viscosity (e.g., a triggering of a vehicular airbag sensor, detection of an earthquake, a proximity warning, etc.). For instance, the computing entity

20-1 determines that the desired response **188** to slow down the object **12-1** is warranted based on reaching a maximum piston velocity threshold level for object **12-1**.

[0145] Having determined the desired response **188** for the STF, a fourth step of the example method of operation includes the computing entity **20-1** generating a fluid activation based on the desired response for the STF, where the fluid activation is output to the set of fluid manipulation emitters positioned proximal to the chamber **16**. The generating of the fluid activation includes one or more of performing a lookup in a fluid activation table for fluid activation output values versus desired viscosity increases, dynamically calculating the fluid activation output values based on a gap in viscosity levels, and receiving the fluid activation from another computing entity. For example, the computing entity **20-1** determines the fluid activation to affect the STF such that the viscosity is raised to lead to an abrupt slow down of the piston through the STF as the actual response moves from a position at a time associated with **Y1** to another position at another time associated with **Y2**. Having determined the fluid activation, the computing entity **20-1** outputs fluid activation **234-1-1** and **234-1-2** to the emitters **114-1-1** and **114-1-2** respectively to affect the viscosity of the STF **42**.

[0146] FIG. **10C** further illustrates the example of operation of the method for the controlling the operational aspects where, having generated the fluid activation, the computing entity **20-1** detects an oscillation associated with the object **12-1** and piston **36**. For example, the computing entity **20-1** re-measures the fluid response to determine one or more of piston velocity **182**, piston position **184**, and shear force **186**. Having determined velocity and position, the computing entity **20-1** determines actual response at a time **Y2** going to **Y3** and compares the piston velocity versus force applied to the piston to the desired response curve. The computing entity **20-1** indicates the acylation when the velocity changes between positive and negative for several cycles.

[0147] Having detected the oscillation, a sixth step of the example of operation of the method for the controlling the operational aspects includes the computing entity **20-1** generating an updated fluid activation based on the detected oscillation. The oscillation has an associated frequency and magnitude pattern. In an example of generating the updated fluid activation, the computing entity **20-1** determines that and updated desired response should include a dampened oscillation to lead the piston and object **12-12** lower magnitudes of the oscillation. The computing entity **20-1** outputs the fluid activation **234-1-1** and **234-1-2** to the emitters **114-1-1** and **114-1-2** respectively to facilitate slowing down the oscillation to that of the updated desired response.

[0148] The method described above in conjunction with a processing module of any computing entity of the mechanical and computing system of FIG. **1** can alternatively be performed by other modules of the system of FIG. **1** or by other devices. In addition, at least one memory section that is non-transitory (e.g., a non-transitory computer readable storage medium, a non-transitory computer readable memory organized into a first memory element, a second memory element, a third memory element, a fourth element section, a fifth memory element, a sixth memory element, etc.) that stores operational instructions can, when executed by one or more processing modules of the one or more computing entities of the computing system **10**, cause one or more computing devices of the mechanical and computing system of FIG. **1** to perform any or all of the method steps described above.

[0149] FIGS. **11A-11B** are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects. The mechanical and computing system includes the head unit **10-1** of FIG. **1**, the object **12-1** of FIG. **1**, and the computing entity **20-1** of FIG. **1**.

[0150] In particular, the head unit **10-1** for controlling motion of the object **12-1** includes shear thickening fluid (STF) **42**. The STF **42** is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates. The second range of shear rates are greater than the first range of shear rates.

[0151] The head unit **10-1** further includes a chamber **16**, the chamber configured to contain a

portion of the STF. The chamber includes a piston compartment **23** and an auxiliary compartment **241**.

[0152] The head unit **10-1** further includes an auxiliary bypass **244** configured within the chamber **16**. The auxiliary bypass **244** couples the piston compartment **23** and the auxiliary compartment **241** controlling flow of the STF **42** between the piston compartment and the auxiliary compartment.

[0153] The head unit **10-1** further includes a piston **36** housed at least partially radially within the piston compartment **23** of the chamber **16**. The piston is configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston from the object **12-1**. The movement of the piston includes one of traveling through the piston compartment of the chamber in an inward direction (e.g., towards a back channel partition **242** separating the piston compartment **23** from the auxiliary compartment **241**) or traveling through the piston compartment of the chamber in an outward direction (e.g., towards a plunger bushing **32**).

[0154] The head unit **10-1** further includes a set of fluid flow sensors **116-1-1** and **116-1-2** positioned proximal to the chamber. The set of fluid flow sensors provide a fluid response **232-1-1** and **232-1-2** from the STF.

[0155] The head unit **10-1** further includes a set of fluid manipulation emitters **114-1-1** and **114-1-2** positioned proximal to the chamber. The set of fluid manipulation emitters provide a fluid activation to the STF such that one of the first range of shear rates or the second range of shear rates is selected for the STF within the piston compartment. The fluid activation further includes controlling the auxiliary bypass **244**.

[0156] FIG. **11A** illustrates an example of operation of a method for the controlling the operational aspects. A first step of the example of operation includes the computing entity **20-1** interpreting a fluid response from the set of fluid flow sensors to produce a piston velocity and a piston position of the piston associated with the head unit device. For example, the computing entity **20-1** interprets fluid responses **232-1-1** and **232-1-2** from the STF **42** (e.g., in response to varying responsiveness of the particles of the STF) to produce the piston velocity and the piston position.

[0157] The interpreting the fluid flow response from the set of fluid flow sensors to produce the piston velocity and the piston position of the piston includes a series of sub-steps. A first sub-step includes inputting, from one or more fluid flow sensors of the set of fluid flow sensors, a set of fluid flow signals over a time range. For example, the computing entity **20-1** receives fluid responses **232-1-1** and **232-1-2** over the time range, where the fluid responses include the fluid flow signals.

[0158] A second sub-step includes determining the fluid flow response of the set of fluid flow sensors based on the set of fluid flow signals. For example, the computing entity **20-1** interprets the fluid flow signals to produce the fluid flow response.

[0159] A third sub-step includes determining the piston velocity based on the fluid flow response of the set of fluid flow sensors over the time range. For example, the computing entity **20-1** calculates piston velocity based on changes in the fluid flow response over the time range.

[0160] A fourth sub-step includes determining the piston position based on the piston velocity and a real-time reference. For example, the computing entity **20-1** calculates the piston position based on time in the piston velocity as the piston moves through the chamber.

[0161] As yet another example of interpreting the fluid response **232-1-1** and **232-1-2**, the computing entity **20-1** compares the fluid response **232-1-1** and **232-1-2** to previous measurements of fluid flow versus piston velocity and piston position to produce the piston velocity **182** and piston position **184**. As a still further example of the interpreting the fluid response **232-1-1** and **232-1-2**, the computing entity **20-1** extracts the piston velocity **182** and the piston position **184** directly from the fluid response **232-1-1** and/or **232-1-2** when the sensors **116-1-1** and **116-1-2** generate the piston velocity and piston position directly.

[0162] A second step of the example of operation includes the computing entity **20-1** determining a

shear force **186** based on the piston velocity **182** and the piston position **184**. The determining the shear force based on the piston velocity and the piston position includes one approach of a variety of approaches. A first approach includes extracting the shear force directly from the fluid flow response when one or more fluid flow sensors of the set of fluid flow sensors outputs a shear force encoded signal. For example, the computing entity **20-1** extracts the shear force **186** directly from the fluid responses **232-1-1** and **232-1-2**. In an instance, the shear force **186** reveals the piston velocity versus force applied to the piston curve as illustrated in FIG. **11A**, where at a current time of interpreting the fluid flow response, the force and piston velocity are at a point **X1**.

[0163] A second approach includes determining the shear force utilizing the piston velocity and stored data for piston velocity versus shear force for the STF. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**.

[0164] A third approach includes determining the shear force utilizing the piston position and stored data for piston position and an auxiliary bypass status **246** versus shear force for the STF within the chamber. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42** based on an actual valve opening status of the auxiliary bypass **244**.

[0165] FIG. **11B** further illustrates the example of operation of the method for the controlling the operational aspects. A third step of the example of operation includes the computing entity **20-1** determining a desired response **188** for the STF based on one or more of the shear force **186** and the piston velocity **182** and the piston position **184**. The desired response **188** includes continuing to follow a nominal response curve associated with the STF without modifying the functioning of the STF. The desired response **188** further includes modifying the function of the STF to further slow down the object **12-1** or to allow the object **12-1** to speed up at a velocity associated with the nominal response.

[0166] The determining the desired response for the STF based on one or more of the shear force, the piston velocity, and piston position includes one or more approaches. A first approach includes interpreting a request associated with modifying one or more of object velocity and object position. For example, the computing entity **20-1** interprets a request from another computing entity to update the desired response for the STF to decrease viscosity to speed up the object **12-1**.

[0167] A second approach includes interpreting guidance from a chamber database. For example, the computing entity **20-1** interprets data from the chamber database **34** of FIG. **1A** to identify a response for the STF. For instance, the response for the STF is updated to decrease viscosity when historical information in the chamber database **34** indicates that a decrease in viscosity is desired based on a current piston position and current shear force.

[0168] A third approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the piston position is greater than a maximum piston position threshold level. A fourth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the piston position is less than a minimum piston position threshold level.

[0169] A fifth approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the piston velocity is greater than a maximum piston velocity threshold level. A sixth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the piston velocity is less than a minimum piston velocity threshold level.

[0170] A seventh approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the shear force is less than a minimum shear force threshold level. An eighth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the shear force is greater than a maximum shear force threshold level.

[0171] A ninth approach includes detecting an environmental condition warranting a change in viscosity of the STF. For example, the computing entity **20-1** determines to change the viscosity of the STF when an emergency is detected.

[0172] A tenth approach includes establishing the desired response to include activation of the auxiliary bypass to cause flow of the STF from the piston compartment to the auxiliary compartment when establishing the desired response to include facilitating the first range of shear rates. An eleventh approach includes establishing the desired response to include activation of the auxiliary bypass to cause flow of the STF from the auxiliary compartment to the piston compartment when establishing the desired response to include facilitating the second range of shear rates.

[0173] Having determined the desired response **188** for the STF, a fourth step of the example method of operation includes the computing entity **20-1** activating the auxiliary bypass **244** in accordance with the desired response **188** for the STF to adjust the STF flow between the piston compartment **23** and the auxiliary compartment **241** to cause selection of one of the first range of shear rates or the second range of shear rates for the STF within the piston compartment **23**.

[0174] The activating the auxiliary bypass in accordance with the desired response for the STF to adjust the STF flow between the piston compartment and the auxiliary compartment includes one or more of a variety of approaches.

[0175] A first approach includes generating a fluid activation to cause flow of the STF from the piston compartment to the auxiliary compartment when the desired response for the STF includes facilitating the first range of shear rates. For instance, the computing entity **20-1** outputs the fluid activation **234-1-1** to the auxiliary bypass **244** to cause the STF to retreat to the auxiliary compartment **241** thusly reducing STF shear force in the piston compartment **23** and selecting the first range of shear rates (e.g., lower viscosity to speed up the object **12-1** moving from position X1 to a position X2 as illustrated in FIG. **11B**).

[0176] A second approach includes generating the fluid activation to cause flow of the STF from the auxiliary compartment to the piston compartment when the desired response for the STF includes facilitating the second range of shear rates. For instance, the computing entity **20-1** outputs the fluid activation **234-1-1** to the auxiliary bypass **244** to cause the STF to move into the piston compartment **23** thusly increasing STF shear forces in the piston compartment **23** and selecting the second range of shear rates (e.g., higher viscosity to slow down the object **12-1**).

[0177] In an embodiment, the process repeats where further fluid response is utilized to recalculate the desired response. The computing entity **20-1** updates the adjustment to the auxiliary bypass **244** and/or the emitters **114-1-1** and **114-1-2** based on the recalculated desired response.

[0178] The method described above in conjunction with a processing module of any computing entity of the mechanical and computing system of FIG. **1** can alternatively be performed by other modules of the system of FIG. **1** or by other devices. In addition, at least one memory section that is non-transitory (e.g., a non-transitory computer readable storage medium, a non-transitory computer readable memory organized into a first memory element, a second memory element, a third memory element, a fourth element section, a fifth memory element, a sixth memory element, etc.) that stores operational instructions can, when executed by one or more processing modules of the one or more computing entities of the computing system **10**, cause one or more computing devices of the mechanical and computing system of FIG. **1** to perform any or all of the method steps described above.

[0179] FIGS. **12A-12B** are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects. The mechanical and computing system includes the head unit **10-1** of FIG. **1**, the object **12-1** of FIG. **1**, and the computing entity **20-1** of FIG. **1**.

[0180] In particular, the head unit **10-1** for controlling motion of the object **12-1** includes shear thickening fluid (STF) **42**. The STF **42** is configured to have a decreasing viscosity in response to a

first range of shear rates and an increasing viscosity in response to a second range of shear rates. The second range of shear rates are greater than the first range of shear rates.

[0181] The head unit **10-1** further includes an alternative shear thickening fluid (ASTF) **256**. The ASTF **256** is configured to have a decreasing viscosity in response to a third range of shear rates and an increasing viscosity in response to a fourth range of shear rates. The fourth range of shear rates are greater than the third range of shear rates.

[0182] The head unit **10-1** further includes a chamber **16**. The chamber configured to contain a portion of the STF and a portion of the ASTF. The chamber includes a piston compartment **23** and an alternative reservoir **250**. The alternative reservoir contains a portion of the ASTF during a dormant timeframe (e.g., before a subsequent activation timeframe where a characteristic of the head unit is changed).

[0183] The head unit **10-1** further includes an evacuator **255** configured within the chamber **16**. The evacuator **255** couples the piston compartment **23** and the alternative reservoir **250** controlling flow of at least some of the STF from the piston compartment to the alternative reservoir during the activation timeframe. The activation timeframe is subsequent to the dormant timeframe.

[0184] The head unit **10-1** further includes a reservoir injector **254** configured within the chamber. The reservoir injector **254** couples the piston compartment **23** and the alternative reservoir **250** controlling flow of the ASTF **256** from the alternative reservoir **250** to the piston compartment **23** to mix with the STF during the activation timeframe to produce a mixture of the STF and the ASTF such that one of the first range of shear rates, the second range of shear rates, a modified first range of shear rates, or a modified second range of shear rates is selected for the mixture of the STF and the ASTF within the piston compartment. The mixture of the STF and the ASTF is configured to have a decreasing viscosity in response to the modified first range of shear rates and an increasing viscosity in response to the modified second range of shear rates, wherein the modified second range of shear rates are greater than the modified first range of shear rates.

[0185] In an embodiment, a reservoir partition **252** separates the alternative reservoir **250** and the piston compartment **23** within the chamber **16**.

[0186] The head unit **10-1** further includes a piston **36** housed at least partially radially within the piston compartment **23** of the chamber **16**. The piston is configured to exert pressure against one or more of the STF **42** and the ASTF **256** in response to movement of the piston **36** from a force applied to the piston from the object **12-1**. The movement of the piston includes one of traveling through the piston compartment of the chamber in an inward direction or traveling through the piston compartment of the chamber in an outward direction. The piston is further configured to affect evacuation of the at least some of the STF from the piston compartment through the evacuator **255** to the alternative reservoir in response to the piston traveling through the piston compartment of the chamber in the inward direction during the activation timeframe.

[0187] In an embodiment, the head unit **10-1** further includes a set of fluid flow sensors **116-1-1** and **116-1-2** positioned proximal to the chamber **16**. The set of fluid flow sensors provide a fluid response **232-1-1** and **232-1-2** from the STF **42**.

[0188] In an embodiment, the head unit **10-1** further includes a set of fluid manipulation emitters **114-1-1** and **114-1-2** positioned proximal to the chamber **16**. The set of fluid manipulation emitters provide a fluid activation to the one or more of the STF **42** and the ASTF **256** such that one of the first range of shear rates, the second range of shear rates, a modified first range of shear rates, or a modified second range of shear rates is selected for the one or more of STF and the ASTF within the piston compartment **23**.

[0189] The fluid activation further includes one or more of controlling the reservoir injector **254** to control inflow of the alternative shear thickening fluid **256** from the alternative reservoir **250** to the piston compartment **23** and controlling the flow of STF from the piston compartment to the alternative reservoir causing a mixture of the two shear thickening fluids. In an example, such inflow occurs only once, during an emergency. The mixture of the STF and the ASTF is configured

to have a decreasing viscosity in response to the modified first range of shear rates and an increasing viscosity in response to the modified second range of shear rates. The modified second range of shear rates are greater than the modified first range of shear rates.

[0190] FIG. 12A illustrates an example of operation of a method for the controlling the operational aspects. A first step of the example of operation includes the computing entity **20-1** interpreting fluid responses **232-1-1** and **232-1-2** from the fluid flow sensors of the STF **42** (e.g., in response to varying responsiveness of the particles of the STF) to produce a piston velocity and piston position of the piston associated with the head unit. For example, the computing entity **20-1** interprets fluid responses **232-1-1** and **232-1-2** from the sensors **116-1-1** and **116-1-24** the STF **42** (e.g., in response to varying responsiveness of the particles of the STF) to produce the piston velocity and the piston position.

[0191] The interpreting the fluid flow response from the set of fluid flow sensors to produce the piston velocity and the piston position of the piston includes a series of sub-steps. A first sub-step includes inputting, from one or more fluid flow sensors of the set of fluid flow sensors, a set of fluid flow signals over a time range. For example, the computing entity **20-1** receives fluid responses **232-1-1** and **232-1-2** over the time range, where the fluid responses include the fluid flow signals.

[0192] A second sub-step includes determining the fluid flow response of the set of fluid flow sensors based on the set of fluid flow signals. For example, the computing entity **20-1** interprets the fluid flow signals to produce the fluid flow response.

[0193] A third sub-step includes determining the piston velocity based on the fluid flow response of the set of fluid flow sensors over the time range. For example, the computing entity **20-1** calculates piston velocity based on changes in the fluid flow response over the time range.

[0194] A fourth sub-step includes determining the piston position based on the piston velocity and a real-time reference. For example, the computing entity **20-1** calculates the piston position based on time in the piston velocity as the piston moves through the chamber.

[0195] As yet another example of interpreting the fluid response **232-1-1** and **232-1-2**, the computing entity **20-1** compares the fluid response **232-1-1** and **232-1-2** to previous measurements of fluid flow versus piston velocity and piston position to produce the piston velocity **182** and piston position **184**. As a still further example of the interpreting the fluid response **232-1-1** and **232-1-2**, the computing entity **20-1** extracts the piston velocity **182** and the piston position **184** directly from the fluid response **232-1-1** and/or **232-1-2** when the sensors **116-1-1** and **116-1-2** generate the piston velocity and piston position directly.

[0196] A second step of the example of operation includes the computing entity **20-1** determining a shear force **186** based on the piston velocity **182** and the piston position **184**. The determining the shear force based on the piston velocity and the piston position includes one approach of a variety of approaches. A first approach includes extracting the shear force directly from the fluid flow response when one or more fluid flow sensors of the set of fluid flow sensors outputs a shear force encoded signal. For example, the computing entity **20-1** extracts the shear force **186** directly from the fluid responses **232-1-1** and **232-1-2**. In an instance, the shear force **186** reveals the piston velocity versus force applied to the piston curve as illustrated in FIG. 12A, where at a current time of interpreting the fluid flow response, the force and piston velocity are at a point **X1**.

[0197] A second approach includes determining the shear force utilizing the piston velocity and stored data for piston velocity versus shear force for the STF, the ASTF, and the mixture of the STF and the ASTF. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force.

[0198] A third approach includes determining the shear force utilizing the piston position and stored data for piston position and a status of the reservoir injector versus shear force for the one of the STF, the ASTF, and the mixture of the STF and the ASTF within the chamber. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity

and position versus shear force based on an actual valve opening status of the reservoir injector **254**. In an instance, the shear force **186** reveals the piston velocity versus force applied to the piston curve as illustrated in FIG. **12A**, where at a current time of interpreting the fluid response, the force and piston velocity are at a point **X1**.

[0199] FIG. **12B** further illustrates the example of operation of the method for the controlling the operational aspects. A third step of the example of operation includes the computing entity **20-1** determining a desired response **188**, for the one or more of the STF and the ASTF based on one or more of the shear force **186** and the piston velocity **182** and the piston position **184**, where the desired response **188** includes injecting the alternative STF **256** into the back channel **24** (e.g., during the activation timeframe). As an example, the desired response **188** further includes modifying the function of the STF by mixing it with the alternative STF to further slow down the object **12-1** associated with the new desired response.

[0200] The determining the desired response for the one or more of the STF and the ASTF based on one or more of the shear force, the piston velocity, and piston position includes one or more approaches. A first approach includes interpreting a request associated with modifying one or more of object velocity and object position. For example, the computing entity **20-1** interprets a request from another computing entity to update the desired response for the STF to increase viscosity to slow down the object **12-1**.

[0201] A second approach includes interpreting guidance from a chamber database. For example, the computing entity **20-1** interprets data from the chamber database **34** of FIG. **1A** to identify a response. For instance, the response is to establish and/or updated to decrease viscosity when historical information in the chamber database **34** indicates that a decrease in viscosity is desired based on a current piston position and current shear force.

[0202] A third approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the piston position is greater than a maximum piston position threshold level. A fourth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the piston position is less than a minimum piston position threshold level.

[0203] A fifth approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the piston velocity is greater than a maximum piston velocity threshold level. A sixth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the piston velocity is less than a minimum piston velocity threshold level.

[0204] A seventh approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the shear force is less than a minimum shear force threshold level. An eighth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the shear force is greater than a maximum shear force threshold level.

[0205] A ninth approach includes detecting an environmental condition warranting a change in viscosity of the STF. For example, the computing entity **20-1** determines to change the viscosity of the STF when a previous emergency has been resolved.

[0206] A tenth approach includes establishing the desired response **188** to include activation of the evacuator and the reservoir injector to cause the flow of the STF from the piston compartment to the alternative reservoir and to cause the flow of the ASTF from the alternative reservoir to the piston compartment when establishing the desired response to include facilitating the modified first range of shear rates. In an embodiment, the modified first range of shear rates is less than the first range of shear rates.

[0207] An eleventh approach includes establishing the desired response to include activation of the evacuator and the reservoir injector to cause the flow of the STF from the piston compartment to the alternative reservoir and to cause the flow of the ASTF from the alternative reservoir to the

piston compartment when establishing the desired response to include facilitating the modified second range of shear rates. In an embodiment, the modified second range of shear rates is greater than the second range of shear rates. In an instance, the desired response **188** includes slowing down the velocity of the piston from the point **X1** to a point **X2** as illustrated in FIG. **12B**.

[0208] Having determined the desired response **188** for the STF, a fourth step of the example method of operation includes the computing entity **20-1** activating the reservoir injector **254** in accordance with the desired response **188** for the one or more of the STF and the ASTF to adjust the flow of the ASTF **256** from the alternative reservoir **250** to the piston compartment **23** to cause selection of one of the first range of shear rates, the second range of shear rates, the modified first range of shear rates, or the modified second range of shear rates for the one or more of STF and the ASTF within the piston compartment **23**.

[0209] The activating the reservoir injector in accordance with the desired response for the one or more of the STF and the ASTF to adjust the ASTF flow from the alternative reservoir to the piston compartment includes one or more sub-steps. A first sub-step includes generating a fluid activation to cause flow of the STF from the piston compartment to the alternative reservoir.

[0210] A second sub-step includes generating a fluid activation to cause flow of the ASTF from the alternative reservoir to the piston compartment. For example, the computing entity **20-1** generates the fluid activation **234-1-1** to open the reservoir injector **254** when the alternative STF **256** is associated with the third range of shear rates (e.g., less than the first range of shear rates) such that the modified first range of shear rates is less than the first range of shear rates. As another example, the computing entity **20-1** generates the fluid activation **234-1-1 2** open the reservoir injector **254** when the alternative STF **256** is associated with the fourth range of shear rates (e.g., greater than the second range of shear rates) such that the modified second range of shear rates is greater than the second range of shear rates to raise the viscosity of the fluid within the piston compartment **23** and slow down the object **12-1** moving from the point **X1** to the point **X2** as illustrated in FIG. **12B**.

[0211] A third sub-step includes outputting the fluid activation to the evacuator **255** and the reservoir injector **254**. For example, the computing entity **20-1** outputs the fluid activation **234-1-1** to the reservoir injector **254** to facilitate opening of the reservoir injector **254** enabling the mixing of the alternative STF **256** and the STF **42** to produce the mixture. Having established the mixture within the piston compartment **23**, the object **12-1** moves in accordance with the desired response **188**.

[0212] In an alternative embodiment, the reservoir injector **254**, on its own, mechanically detects an undesired attribute within the back channel **24** (e.g., pressure greater than a high pressure over threshold level) and opens to initiate the inflow of the alternative STF **256** into the back channel **24** to mix with the STF **42** to enable an emergency slow down of the object **12-1**.

[0213] The method described above in conjunction with a processing module of any computing entity of the mechanical and computing system of FIG. **1** can alternatively be performed by other modules of the system of FIG. **1** or by other devices. In addition, at least one memory section that is non-transitory (e.g., a non-transitory computer readable storage medium, a non-transitory computer readable memory organized into a first memory element, a second memory element, a third memory element, a fourth element section, a fifth memory element, a sixth memory element, etc.) that stores operational instructions can, when executed by one or more processing modules of the one or more computing entities of the computing system **10**, cause one or more computing devices of the mechanical and computing system of FIG. **1** to perform any or all of the method steps described above.

[0214] FIGS. **13A-13B** are schematic block diagrams of another embodiment of a mechanical and computing system illustrating another example of controlling operational aspects. The mechanical and computing system includes the head unit **10-1** of FIG. **1**, the object **12-1** of FIG. **1**, and the computing entity **20-1** of FIG. **1**.

[0215] In particular, the head unit **10-1** for controlling motion of the object **12-1** includes the chamber **16** filled at least in part with the shear thickening fluid (STF) **42**. The chamber **16** includes a piston compartment. The piston compartment includes the front channel **26** and the back channel **24**, where the variable partition **260** partitions the back channel **24**.

[0216] The piston is housed at least partially radially within the piston compartment of the chamber **16**. The piston **36** is configured to exert pressure against the shear thickening fluid in response to movement of the piston **36** from a force applied to the piston **36** via the plunger **28** from the object **12-1**.

[0217] The movement of the piston **36** includes one of traveling through the chamber **16** in an inward direction or traveling through the chamber **16** in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0218] The head unit **10-1** further includes a variable partition **260** positioned within the chamber between the piston and a closed end of the chamber to dynamically affect volume of the chamber based on activation of the variable partition. The head unit **10-1** further includes a set of fluid flow sensors positioned proximal to the chamber **16** and a set of fluid manipulation emitters positioned proximal to the chamber **16**. The set of fluid flow sensors provide a fluid response from the STF. The set of fluid manipulation emitters provide a fluid activation to the STF. For example, sensors **116-1-1** and **116-1-2** and emitters **114-1-1** and **114-1-2** are proximal to the chamber, where the sensors and emitters sense and emit energy respectively to interact with the STF **42**.

[0219] FIG. **13A** illustrates an example of operation of a method for the controlling the operational aspects. A first step of the example of operation includes the computing entity **20-1** interpreting fluid responses **232-1-1** and **232-1-2** from the STF **42** (e.g., in response to varying responsiveness of the particles of the STF) to produce a piston velocity and a piston position of the piston **36**. The set of fluid sensors are positioned proximal to the head unit **10-1** for controlling motion of the object **12-1**, where the head unit includes the chamber filled at least in part with a shear thickening fluid (STF).

[0220] The piston is housed at least partially radially within the chamber and the piston is configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston from the object **12-1**. The movement of the piston includes one of traveling through the chamber in an inward direction or traveling through the chamber in an outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates. The chamber includes the variable partition to dynamically affect volume of the chamber.

[0221] The interpreting the fluid flow response from the set of fluid flow sensors to produce the piston velocity and the piston position of the piston includes a series of sub-steps. A first sub-step includes inputting, from one or more fluid flow sensors of the set of fluid flow sensors, a set of fluid flow signals over a time range. For example, the computing entity **20-1** receives fluid responses **232-1-1** and **232-1-2** over the time range, where the fluid responses include the fluid flow signals.

[0222] A second sub-step includes determining the fluid flow response of the set of fluid flow sensors based on the set of fluid flow signals. For example, the computing entity **20-1** interprets the fluid flow signals to produce the fluid flow response.

[0223] A third sub-step includes determining the piston velocity based on the fluid flow response of the set of fluid flow sensors over the time range. For example, the computing entity **20-1** calculates piston velocity based on changes in the fluid flow response over the time range.

[0224] A fourth sub-step includes determining the piston position based on the piston velocity and a real-time reference. For example, the computing entity **20-1** calculates the piston position based on time in the piston velocity as the piston moves through the chamber.

[0225] As yet another example of interpreting the fluid response **232-1-1** and **232-1-2**, the

computing entity **20-1** compares the fluid response **232-1-1** and **232-1-2** to previous measurements of fluid flow versus piston velocity and piston position to produce the piston velocity **182** and piston position **184**. As a still further example of the interpreting the fluid response **232-1-1** and **232-1-2**, the computing entity **20-1** extracts the piston velocity **182** and the piston position **184** directly from the fluid response **232-1-1** and/or **232-1-2** when the sensors **116-1-1** and **116-1-2** generate the piston velocity and piston position directly.

[0226] A second step of the example of operation includes the computing entity **20-1** determining a shear force **186** based on the piston velocity **182** and the piston position **184**. The determining the shear force based on the piston velocity and the piston position includes one approach of a variety of approaches. A first approach includes extracting the shear force directly from the fluid flow response when one or more fluid flow sensors of the set of fluid flow sensors outputs a shear force encoded signal. For example, the computing entity **20-1** extracts the shear force **186** directly from the fluid responses **232-1-1** and **232-1-2**. In an instance, the shear force **186** reveals the piston velocity versus force applied to the piston curve as illustrated in FIG. **13A**, where at a current time of interpreting the fluid flow response, the force and piston velocity are at a point **X1**.

[0227] A second approach includes determining the shear force utilizing the piston velocity and stored data for piston velocity versus shear force for the STF. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**.

[0228] A third approach includes determining the shear force utilizing the piston position and stored data for piston position versus shear force for the STF within the chamber. For example, the computing entity **20-1** compares the velocity and position to stored data for instantaneous velocity and position versus shear force for the STF **42**.

[0229] FIG. **13B** further illustrates the example of operation of the method for the controlling the operational aspects. A third step of the example of operation includes the computing entity **20-1** determining a desired response **188** for the STF based on one or more of the shear force **186**, the piston velocity **182**, and the piston position **184**, where the desired response **188** includes moving the variable partition **260** within the back channel **24**. The determining the desired response for the STF based on one or more of the shear force, the piston velocity, and piston position includes one or more approaches. A first approach includes interpreting a request associated with modifying one or more of object velocity and object position. For example, the computing entity **20-1** interprets a request from another computing entity to update the desired response for the STF to increase viscosity to slow down the object **12-1**.

[0230] A second approach includes interpreting guidance from a chamber database. For example, the computing entity **20-1** interprets data from the chamber database **34** of FIG. **1A** to identify an updated response for the STF. For instance, the response for the STF is updated to decrease viscosity when historical information in the chamber database **34** indicates that a decrease in viscosity is desired based on a current piston position and current shear force.

[0231] A third approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the piston position is greater than a maximum piston position threshold level. A fourth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the piston position is less than a minimum piston position threshold level.

[0232] A fifth approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the piston velocity is greater than a maximum piston velocity threshold level. A sixth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the piston velocity is less than a minimum piston velocity threshold level.

[0233] A seventh approach includes establishing the desired response to include facilitating the second range of shear rates to slow down the object when detecting that the shear force is less than

a minimum shear force threshold level. An eighth approach includes establishing the desired response to include facilitating the first range of shear rates to speed up the object when detecting that the shear force is greater than a maximum shear force threshold level.

[0234] A ninth approach includes detecting an environmental condition warranting a change in viscosity of the STF. For example, the computing entity **20-1** determines to change the viscosity of the STF when a triggering of a vehicular airbag sensor is detected. As another example, the computing entity **20-1** determines to change the viscosity of the STF when detecting an earthquake. As yet another example, the computing entity **20-1** determines to change the viscosity of the STF when detecting a proximity warning (e.g., of a certain collision).

[0235] A tenth approach includes establishing the desired response to include activation of the variable partition to expand the volume of the chamber (e.g., move the variable partition away from the piston) when establishing the desired response to include facilitating the first range of shear rates. An eleventh approach includes establishing the desired response to include activation of the variable partition to contract the volume of the chamber (e.g., move the variable partition towards the piston) when establishing the desired response to include facilitating the second range of shear rates.

[0236] Having determined the desired response **188** for the STF, a fourth step of the example method of operation includes the computing entity **20-1** activating the variable partition **260** in accordance with the desired response **188** for the STF to adjust the volume of the chamber. The activating the variable partition in accordance with the desired response for the STF to adjust the volume of the chamber includes one or more approaches. A first approach includes generating a variable partition activation **235** to expand the volume of the chamber when the desired response for the STF includes facilitating the first range of shear rates.

[0237] A second approach includes generating the variable partition activation to contract the volume of the chamber when the desired response for the STF includes facilitating the second range of shear rates. A third approach includes outputting the variable partition activation to the variable partition. For example, the computing entity **20-1** outputs the variable partition activation **235** to the variable partition **260** facilitate moving of the variable partition **260**.

[0238] Alternatively, or in addition to, the activating the variable partition **260** includes adjustment via one or more of the emitters. For example, the computing entity **20-1** determines to move the variable partition **260** further inwards to lower the viscosity of the STF to affect increasing the velocity of the object **12-1** as the actual response moves from the X1 to a position X2 by outputting fluid activation **234-1-1** and **234-1-2** to the emitters **114-1-1** and **114-1-2** respectively to move the variable partition **260** further inwards.

[0239] In an alternative embodiment, the variable partition **260**, on its own, mechanically detects an undesired attribute within the back channel **24** (e.g., pressure greater than a high pressure over threshold level) and moves further inward to initiate the speeding up of the object **12-1**.

[0240] The method described above in conjunction with a processing module of any computing entity of the mechanical and computing system of FIG. **1** can alternatively be performed by other modules of the system of FIG. **1** or by other devices. In addition, at least one memory section that is non-transitory (e.g., a non-transitory computer readable storage medium, a non-transitory computer readable memory organized into a first memory element, a second memory element, a third memory element, a fourth element section, a fifth memory element, a sixth memory element, etc.) that stores operational instructions can, when executed by one or more processing modules of the one or more computing entities of the computing system **10**, cause one or more computing devices of the mechanical and computing system of FIG. **1** to perform any or all of the method steps described above.

[0241] FIGS. **14A-14B** are schematic block diagrams of an embodiment of a mechanical system illustrating an example of controlling operational aspects. The mechanical system includes the head unit **10-1** of FIG. **1** and the object **12-1** of FIG. **1**.

[0242] In particular, the head unit **10-1** for controlling motion of the object **12-1** includes the chamber **16** filled at least in part with the shear thickening fluid (STF) **42**. The chamber **16** includes the front channel **26** and the back channel **24**.

[0243] The piston is housed at least partially radially within the piston compartment of the chamber **16**. The piston **36** is configured to exert pressure against the shear thickening fluid in response to movement of the piston **36** from a force applied to the piston **36** via the plunger **28** from the object **12-1**.

[0244] The movement of the piston **36** includes one of traveling through the chamber **16** in an inward direction or traveling through the chamber **16** in an outward direction. The piston **36** travels toward the back channel **24** and away from the front channel **26** when traveling in the inward direction. The piston travels toward the front channel **26** and away from the back channel **24** when traveling in the outward direction. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates.

[0245] The piston **36** includes a first piston bypass **38-1** between opposite sides of the piston that controls flow of the STF between the opposite sides of the piston from the back channel **24** to the front channel **26** when the piston is traveling through the chamber in the inward direction to cause the STF to react with a first shear threshold effect. The piston **36** further includes a second piston bypass **38-2** between the opposite sides of the piston that controls flow of the STF between the opposite sides of the piston from the front channel **26** to the back channel **24** when the piston **36** is traveling through the chamber in the outward direction to cause the STF to react with a second shear threshold effect.

[0246] In another embodiment, the piston includes a single piston bypass between opposite sides of the piston that controls flow of the STF between the opposite sides of the piston between the back channel and the front channel when the piston is traveling through the chamber to cause the STF to react with a shear threshold effect.

[0247] When the piston **36** includes two or more piston bypasses, each piston bypass includes a one-way check valve and a variable flow valve. When the piston includes one piston bypass, the piston bypass includes the variable flow valve.

[0248] The first piston bypass **38-1** and the second piston bypass **38-2** are configured with a particular diameter of the variable valve to allow the STF to flow through from one channel to the other of the chamber in accordance with a desired overall effect on viscosity of the STF **42**. The graph of FIG. **14A** illustrates a nominal response curve for plunger velocity versus force applied to the plunger taking into account different diameters of the piston bypasses. For example, when the first piston bypass **38-1** has a larger diameter opening as compared to the opening of the second piston bypass **38-2**, the (positive) velocity of the piston is allowed to travel faster since the effect on the viscosity is to lower the viscosity and hence raise the velocity of the piston traveling inward within the chamber.

[0249] FIG. **14A** illustrates an example of operation of the mechanical system for the controlling the operational aspects. A first step of the example of operation includes the piston moving inwards in response to the object **12-1** applying an inward force to the plunger **28** (e.g., pushing). The actual response is depicted on the graph of FIG. **14A** where the actual response follows the nominal response expected for the STF as a point in time of **Y1** is reached.

[0250] When the piston is traveling through the chamber in the inward direction, the first shear threshold effect includes the first range of shear rates when the STF is configured to have the decreasing viscosity and the second range of shear rates when the STF is configured to have the increasing viscosity. A first setting of the variable flow valve of the first piston bypass **38-1** facilitates the first range of shear rates when the STF is to have the decreasing viscosity and a second setting of the variable flow valve facilitates the second range of shear rates when the STF is to have the increasing viscosity. When the piston is traveling through the chamber in the inward

direction, the one-way check valve of the second piston bypass **38-2** prevents STF flow through second piston bypass **38-2**.

[0251] In the alternative embodiment with the one piston bypass, when the piston is traveling through the chamber, a first setting of the variable flow valve of the one piston bypass facilitates the first range of shear rates when the STF is to have the decreasing viscosity and a second setting of the variable flow valve of the one piston bypass facilitates the second range of shear rates when the STF is to have the increasing viscosity.

[0252] A second step of the example of operation includes the STF moving from the back channel **24** through the first piston bypass **38-1** to the front channel **26** at a first velocity to cause the STF to react with a first shear threshold effect. Larger diameters of the first piston bypass **38-1** lowers pressure and shear force within the back channel **24** leading to higher piston velocity as the piston moves inwards.

[0253] FIG. **14B** further illustrates the example of operation of the mechanical system for the controlling the operational aspects. A third step of the example of operation includes the piston **36** moving outwards in response to the object **12-1** applying an outward force to the plunger **28** (e.g., pulling). The actual response is depicted on a graph of FIG. **14B** where the actual response moves to follow the nominal response expected for the STF, at a point in time of Y2, when moving in the outward direction (e.g., negative piston velocity).

[0254] When the piston is traveling through the chamber in the outward direction, the second shear threshold effect includes the first range of shear rates when the STF is configured to have the decreasing viscosity and the second range of shear rates when the STF is configured to have the increasing viscosity. In the alternative embodiment with the one piston bypass, when the piston is traveling through the chamber, the shear threshold effect includes the first range of shear rates when the STF is configured to have the decreasing viscosity and the second range of shear rates when the STF is configured to have the increasing viscosity.

[0255] When the piston is traveling through the chamber in the outward direction, the one-way check valve of the first piston bypass prevents STF flow through the first piston bypass **38-1**. When the piston is traveling through the chamber in the outward direction a first setting of the variable flow valve of the second piston bypass facilitates the first range of shear rates when the STF is to have the decreasing viscosity and a second setting of the variable flow valve of the second piston bypass facilitates the second range of shear rates when the STF is to have the increasing viscosity.

[0256] A third step of the example of operation includes the STF moving from the front channel **26** through the second piston bypass **38-2** to the back channel **24** at a second velocity to cause the STF **42** to react with a second shear threshold effect. The second velocity is less than the first velocity and the second shear threshold effect is more abrupt than the first shear threshold effect when the diameter of the second piston bypass **38-2** is less than the diameter of the first piston bypass **38-1**. As a result, the mechanical system provides an unequal bidirectional response for the inward and outward motion of the object **12-1**.

[0257] FIGS. **15A-15E** are schematic block diagrams of an embodiment of a mechanical system illustrating an example of controlling operational aspects. The mechanical system provides a door closer system to automatically facilitate closing of an open door, where the closing includes a so-called soft close at the end of travel of the door as it reenters a frame surrounding the door.

[0258] FIG. **15A** illustrates an example embodiment of the door closer system **300** that includes a casing **302**, one or more articulating arms **304**, coupled by at least one arm pivot **314**, and attached to an anchor **310** to facilitate connection of the door closer to the doorframe **308** associated with the door **306**. The door closer system further includes a driveshaft **312** that couples one end of the one or more articulating arms to further elements of the door closer system included within the casing **302** as described below. In an example of operation, the driveshaft rotates in a counterclockwise fashion when the door is closing. As another example, the driveshaft rotates in a clockwise fashion when the door is opening.

[0259] FIG. 15B further illustrates the example embodiment of the door closer system **300**, where the casing **302** includes a motion conversion aspect of a plunger. The motion conversion aspect includes a motion conversion assembly configured to mechanically join motion of the door with rotation of the driveshaft **312**. The motion conversion aspect further includes a drive gear **316** coupled to the driveshaft **312** such that the rotation of the driveshaft **312** causes rotation of the drive gear **316**. The drive gear **316** is configured to cause engagement with a track of the plunger such that the plunger travels based on the motion of the door. The plunger and track are discussed in greater detail with reference to FIG. 15C.

[0260] The motion conversion assembly includes at least one of an articulating arm assembly that includes one or more articulating arms **304**, at least one arm pivot **314** coupling the one or more articulating arms, the anchor **310** at an end of the one or more articulating arms, and coupled to the driveshaft **312** at an opposite end of the one or more articulating arms. In an example of operation, as the door opens, the articulating arm assembly opens up causing a clockwise rotation of the driveshaft **312**.

[0261] Alternatively, in another embodiment, the motion conversion assembly includes a hinge assembly that includes two leaves. The anchor **310** is coupled to a first leaf of the two leaves and a second leaf of the two leaves coupled to the driveshaft **312**. In an example of operation, the driveshaft **312** rotates clockwise when the door is opened as the two leaves separate.

[0262] FIG. 15C further illustrates the example embodiment of the door closer system **300**, where the door closer system includes a shear thickening fluid (STF) **42**. The STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates, wherein the second range of shear rates are greater than the first range of shear rates.

[0263] The door closer system further includes a chamber **16** that is configured to contain a portion of the STF **42**. The chamber **16** includes a front channel **26** and a back channel **24**.

[0264] The door closer system further includes a piston **36** housed at least partially radially within the chamber. The piston is configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston. The movement of the piston includes one of traveling through the chamber in an inward direction and traveling through the chamber in an outward direction. The piston **36** travels toward the back channel **24** and away from the front channel **26** when traveling in the inward direction. The piston **36** travels toward the front channel **26** and away from the back channel **24** when traveling in the outward direction.

[0265] The door closer system further includes a plunger **28** coupled to the piston **36** and to a spring **320** of the door closer system. The plunger **28** is configured with a motion conversion aspect to mechanically join motion of the door with the movement of the piston and to provide compression of the spring based on an opening motion of the door. The movement of the piston includes the traveling through the chamber in the inward direction when the motion conversion aspect converts a closing motion of the door. The movement of the piston further includes the traveling through the chamber in the outward direction when the motion conversion aspect converts the opening motion of the door.

[0266] The motion conversion aspect is further configured to cause a variety of outcomes. A first example outcome includes the spring **320** to hold stored energy as a result of the opening motion of the door. For example, the spring **320** is compressed when the doors open and storing the energy.

[0267] A second example outcome includes the spring to release the stored energy to facilitate the closing motion of the door. For example, when the door is free to close (e.g., no one is holding it open), the spring pushes on the plunger which runs a track **318** on teeth of the drive gear **316** which rotates the driveshaft counterclockwise to facilitate the closing of the door.

[0268] The third example outcome includes regulating a velocity of the closing motion of the door as a result of the piston causing the increasing viscosity in response to the second range of shear rates. FIG. 15D illustrates an example of the door just closing where the spring pushes the plunger

which pushes the piston into the chamber compressing the STF into the back channel, the second range of shear rates is triggered causing the increasing of the viscosity of the STF causing the piston to slow down and hence the plunger slows down causing the teeth of the drive gear **316** to slow down the closing of the door to provide a desired soft closing effect.

[0269] Returning to FIG. **15C**, the piston **36** further includes one or more of a first piston bypass of one or more piston bypasses **38** between opposite sides of the piston that controls flow of the STF between the opposite sides of the piston from the back channel to the front channel when the piston is traveling through the chamber in the inward direction (e.g., closing the door) to cause the STF to react with a first shear threshold effect.

[0270] The piston **36** further includes a second piston bypass of the one or more piston bypasses **38** between the opposite sides of the piston that controls flow of the STF between the opposite sides of the piston from the front channel to the back channel when the piston is traveling through the chamber in the outward direction (e.g., opening the door) to cause the STF to react with a second shear threshold effect.

[0271] In an embodiment, the door closer system further includes a chamber bypass **40** between opposite ends of the chamber **16**. The chamber bypass **40** facilitates flow of a portion of the STF between the opposite ends of the chamber when the piston travels through the chamber in the inward or outward direction. For example, the chamber bypass **40** facilitates flow of the STF from the back channel **24** to the front channel **26** when the piston is moving in the inward direction as the doors closing.

[0272] The door closer system further includes a plunger bushing **32** configured to guide the plunger **28** into the chamber **16**. The plunger bushing **32** facilitates containment of the STF **42** within the chamber **16** (e.g., a seal). The plunger bushing **40** remains in a fixed position relative to the chamber **16**.

[0273] FIG. **15E** illustrates an alternative embodiment of a chamber **16-1** to include a chamber end **322** within the back channel **24**. The chamber and **322** is configured to provide an alternative flow of the STF around the piston **36** from the back channel **24** to the front channel **26** when the piston has traveled through the chamber to the chamber end such that the STF provides the decreasing viscosity in response to the first range of shear rates. For example, the shear is reduced when the STF moves around the piston due to the configuration of the chamber and **322** (e.g., utilizing a larger diameter of the inside of the chamber at the chamber end).

[0274] It is noted that terminologies as may be used herein such as bit stream, stream, signal sequence, etc. (or their equivalents) have been used interchangeably to describe digital information whose content corresponds to any of a number of desired types (e.g., data, video, speech, text, graphics, audio, etc. any of which may generally be referred to as ‘data’).

[0275] As may be used herein, the terms “substantially” and “approximately” provides an industry-accepted tolerance for its corresponding term and/or relativity between items. For some industries, an industry-accepted tolerance is less than one percent and, for other industries, the industry-accepted tolerance is 10 percent or more. Other examples of industry-accepted tolerance range from less than one percent to fifty percent. Industry-accepted tolerances correspond to, but are not limited to, component values, integrated circuit process variations, temperature variations, rise and fall times, thermal noise, dimensions, signaling errors, dropped packets, temperatures, pressures, material compositions, and/or performance metrics. Within an industry, tolerance variances of accepted tolerances may be more or less than a percentage level (e.g., dimension tolerance of less than $\pm 1\%$). Some relativity between items may range from a difference of less than a percentage level to a few percent. Other relativity between items may range from a difference of a few percent to magnitude of differences.

[0276] As may also be used herein, the term(s) “configured to”, “operably coupled to”, “coupled to”, and/or “coupling” includes direct coupling between items and/or indirect coupling between items via an intervening item (e.g., an item includes, but is not limited to, a component, an element,

a circuit, and/or a module) where, for an example of indirect coupling, the intervening item does not modify the information of a signal but may adjust its current level, voltage level, and/or power level. As may further be used herein, inferred coupling (i.e., where one element is coupled to another element by inference) includes direct and indirect coupling between two items in the same manner as “coupled to”.

[0277] As may even further be used herein, the term “configured to”, “operable to”, “coupled to”, or “operably coupled to” indicates that an item includes one or more of power connections, input(s), output(s), etc., to perform, when activated, one or more its corresponding functions and may further include inferred coupling to one or more other items. As may still further be used herein, the term “associated with”, includes direct and/or indirect coupling of separate items and/or one item being embedded within another item.

[0278] As may be used herein, the term “compares favorably”, indicates that a comparison between two or more items, signals, etc., provides a desired relationship. For example, when the desired relationship is that signal 1 has a greater magnitude than signal 2, a favorable comparison may be achieved when the magnitude of signal 1 is greater than that of signal 2 or when the magnitude of signal 2 is less than that of signal 1. As may be used herein, the term “compares unfavorably”, indicates that a comparison between two or more items, signals, etc., fails to provide the desired relationship.

[0279] As may be used herein, one or more claims may include, in a specific form of this generic form, the phrase “at least one of a, b, and c” or of this generic form “at least one of a, b, or c”, with more or less elements than “a”, “b”, and “c”. In either phrasing, the phrases are to be interpreted identically. In particular, “at least one of a, b, and c” is equivalent to “at least one of a, b, or c” and shall mean a, b, and/or c. As an example, it means: “a” only, “b” only, “c” only, “a” and “b”, “a” and “c”, “b” and “c”, and/or “a”, “b”, and “c”.

[0280] As may also be used herein, the terms “processing module”, “processing circuit”, “processor”, “processing circuitry”, and/or “processing unit” may be a single processing device or a plurality of processing devices. Such a processing device may be a microprocessor, micro-controller, digital signal processor, microcomputer, central processing unit, field programmable gate array, programmable logic device, state machine, logic circuitry, analog circuitry, digital circuitry, and/or any device that manipulates signals (analog and/or digital) based on hard coding of the circuitry and/or operational instructions. The processing module, module, processing circuit, processing circuitry, and/or processing unit may be, or further include, memory and/or an integrated memory element, which may be a single memory device, a plurality of memory devices, and/or embedded circuitry of another processing module, module, processing circuit, processing circuitry, and/or processing unit. Such a memory device may be a read-only memory, random access memory, volatile memory, non-volatile memory, static memory, dynamic memory, flash memory, cache memory, and/or any device that stores digital information. Note that if the processing module, module, processing circuit, processing circuitry, and/or processing unit includes more than one processing device, the processing devices may be centrally located (e.g., directly coupled together via a wired and/or wireless bus structure) or may be distributedly located (e.g., cloud computing via indirect coupling via a local area network and/or a wide area network). Further note that if the processing module, module, processing circuit, processing circuitry and/or processing unit implements one or more of its functions via a state machine, analog circuitry, digital circuitry, and/or logic circuitry, the memory and/or memory element storing the corresponding operational instructions may be embedded within, or external to, the circuitry comprising the state machine, analog circuitry, digital circuitry, and/or logic circuitry. Still further note that, the memory element may store, and the processing module, module, processing circuit, processing circuitry and/or processing unit executes, hard coded and/or operational instructions corresponding to at least some of the steps and/or functions illustrated in one or more of the Figures. Such a memory device or memory element can be included in an article of manufacture.

[0281] One or more embodiments have been described above with the aid of method steps illustrating the performance of specified functions and relationships thereof. The boundaries and sequence of these functional building blocks and method steps have been arbitrarily defined herein for convenience of description. Alternate boundaries and sequences can be defined so long as the specified functions and relationships are appropriately performed. Any such alternate boundaries or sequences are thus within the scope and spirit of the claims. Further, the boundaries of these functional building blocks have been arbitrarily defined for convenience of description. Alternate boundaries could be defined as long as the certain significant functions are appropriately performed. Similarly, flow diagram blocks may also have been arbitrarily defined herein to illustrate certain significant functionality.

[0282] To the extent used, the flow diagram block boundaries and sequence could have been defined otherwise and still perform the certain significant functionality. Such alternate definitions of both functional building blocks and flow diagram blocks and sequences are thus within the scope and spirit of the claims. One of average skill in the art will also recognize that the functional building blocks, and other illustrative blocks, modules, and components herein, can be implemented as illustrated or by discrete components, application specific integrated circuits, processors executing appropriate software and the like or any combination thereof.

[0283] In addition, a flow diagram may include a “start” and/or “continue” indication. The “start” and “continue” indications reflect that the steps presented can optionally be incorporated in or otherwise used in conjunction with one or more other routines. In addition, a flow diagram may include an “end” and/or “continue” indication. The “end” and/or “continue” indications reflect that the steps presented can end as described and shown or optionally be incorporated in or otherwise used in conjunction with one or more other routines. In this context, “start” indicates the beginning of the first step presented and may be preceded by other activities not specifically shown. Further, the “continue” indication reflects that the steps presented may be performed multiple times and/or may be succeeded by other activities not specifically shown. Further, while a flow diagram indicates a particular ordering of steps, other orderings are likewise possible provided that the principles of causality are maintained.

[0284] The one or more embodiments are used herein to illustrate one or more aspects, one or more features, one or more concepts, and/or one or more examples. A physical embodiment of an apparatus, an article of manufacture, a machine, and/or of a process may include one or more of the aspects, features, concepts, examples, etc., described with reference to one or more of the embodiments discussed herein. Further, from figure to figure, the embodiments may incorporate the same or similarly named functions, steps, modules, etc., that may use the same or different reference numbers and, as such, the functions, steps, modules, etc., may be the same or similar functions, steps, modules, etc. or different ones.

[0285] Unless specifically stated to the contra, signals to, from, and/or between elements in a figure of any of the figures presented herein may be analog or digital, continuous time or discrete time, and single-ended or differential. For instance, if a signal path is shown as a single-ended path, it also represents a differential signal path. Similarly, if a signal path is shown as a differential path, it also represents a single-ended signal path. While one or more particular architectures are described herein, other architectures can likewise be implemented that use one or more data buses not expressly shown, direct connectivity between elements, and/or indirect coupling between other elements as recognized by one of average skill in the art.

[0286] The term “module” is used in the description of one or more of the embodiments. A module implements one or more functions via a device such as a processor or other processing device or other hardware that may include or operate in association with a memory that stores operational instructions. A module may operate independently and/or in conjunction with software and/or firmware. As also used herein, a module may contain one or more sub-modules, each of which may be one or more modules.

[0287] As may further be used herein, a computer readable memory includes one or more memory elements. A memory element may be a separate memory device, multiple memory devices, or a set of memory locations within a memory device. Such a memory device may be a read-only memory, random access memory, volatile memory, non-volatile memory, static memory, dynamic memory, flash memory, cache memory, a quantum register or other quantum memory and/or any other device that stores data in a non-transitory manner. Furthermore, the memory device may be in a form of a solid-state memory, a hard drive memory or other disk storage, cloud memory, thumb drive, server memory, computing device memory, and/or other non-transitory medium for storing data. The storage of data includes temporary storage (i.e., data is lost when power is removed from the memory element) and/or persistent storage (i.e., data is retained when power is removed from the memory element). As used herein, a transitory medium shall mean one or more of: (a) a wired or wireless medium for the transportation of data as a signal from one computing device to another computing device for temporary storage or persistent storage; (b) a wired or wireless medium for the transportation of data as a signal within a computing device from one element of the computing device to another element of the computing device for temporary storage or persistent storage; (c) a wired or wireless medium for the transportation of data as a signal from one computing device to another computing device for processing the data by the other computing device; and (d) a wired or wireless medium for the transportation of data as a signal within a computing device from one element of the computing device to another element of the computing device for processing the data by the other element of the computing device. As may be used herein, a non-transitory computer readable memory is substantially equivalent to a computer readable memory. A non-transitory computer readable memory can also be referred to as a non-transitory computer readable storage medium.

[0288] While particular combinations of various functions and features of the one or more embodiments have been expressly described herein, other combinations of these features and functions are likewise possible. The present disclosure is not limited by the particular examples disclosed herein and expressly incorporates these other combinations.

Claims

1. A door closer system for controlling motion of a door, comprising: shear thickening fluid (STF), wherein the STF is configured to have a decreasing viscosity in response to a first range of shear rates and an increasing viscosity in response to a second range of shear rates, wherein the second range of shear rates are greater than the first range of shear rates; a chamber, the chamber configured to contain a portion of the STF, wherein the chamber includes a front channel and a back channel; a piston housed at least partially radially within the chamber, the piston configured to exert pressure against the shear thickening fluid in response to movement of the piston from a force applied to the piston, wherein the movement of the piston includes one of traveling through the chamber in an inward direction and traveling through the chamber in an outward direction, wherein the piston travels toward the back channel and away from the front channel when traveling in the inward direction, wherein the piston travels toward the front channel and away from the back channel when traveling in the outward direction; and a plunger coupled to the piston and to a spring of the door closer system, the plunger configured with a motion conversion aspect to mechanically join motion of the door with the movement of the piston and to provide compression of the spring based on an opening motion of the door, the movement of the piston including the traveling through the chamber in the inward direction when the motion conversion aspect converts a closing motion of the door and including the traveling through the chamber in the outward direction when the motion conversion aspect converts the opening motion of the door, wherein the motion conversion aspect is further configured to cause: the spring to hold stored energy as a result of the opening motion of the door, the spring to release the stored energy to facilitate the closing motion

of the door, and regulating a velocity of the closing motion of the door as a result of the piston causing the increasing viscosity in response to the second range of shear rates.

2. The door closer system of claim 1, wherein the piston further comprises one or more of: a first piston bypass between opposite sides of the piston that controls flow of the STF between the opposite sides of the piston from the back channel to the front channel when the piston is traveling through the chamber in the inward direction to cause the STF to react with a first shear threshold effect; and a second piston bypass between the opposite sides of the piston that controls flow of the STF between the opposite sides of the piston from the front channel to the back channel when the piston is traveling through the chamber in the outward direction to cause the STF to react with a second shear threshold effect.
 3. The door closer system of claim 1 further comprises: a chamber bypass between opposite ends of the chamber, wherein the chamber bypass facilitates flow of a portion of the STF between the opposite ends of the chamber when the piston travels through the chamber in the inward or outward direction.
 4. The door closer system of claim 1 further comprises: a plunger bushing configured to guide the plunger into the chamber, wherein the plunger bushing facilitates containment of the STF within the chamber, wherein the plunger bushing remains in a fixed position relative to the chamber.
 5. The door closer system of claim 1, wherein the STF comprises: a plurality of nanoparticles, wherein the plurality of nanoparticles includes one or more of an oxide, calcium carbonate, synthetically occurring minerals, naturally occurring minerals, polymers, SiO₂, polystyrene, polymethylmethacrylate, or a mixture thereof.
 6. The door closer system of claim 1, wherein the STF further comprises: one or more of ethylene glycol, polyethylene glycol, ethanol, silicon oils, phenyltrimethicone, or a mixture thereof.
 7. The door closer system of claim 1, wherein the chamber further comprises: a chamber end within the back channel, the chamber end configured to provide an alternative flow of the STF around the piston from the back channel to the front channel when the piston has traveled through the chamber to the chamber end such that the STF provides the decreasing viscosity in response to the first range of shear rates.
 8. The door closer system of claim 1, wherein the motion conversion aspect of the plunger comprises: a motion conversion assembly configured to mechanically join the motion of the door with rotation of a driveshaft; and a drive gear coupled to the driveshaft such that the rotation of the driveshaft causes rotation of the drive gear, the drive gear configured to cause engagement with a track of the plunger such that the plunger travels based on the motion of the door.
 9. The door closer system of claim 8, wherein the motion conversion assembly comprises at least one of: an articulating arm assembly that includes one or more articulating arms, at least one arm pivot coupling the one or more articulating arms, an anchor at an end of the one or more articulating arms, and coupled to the driveshaft at an opposite end of the one or more articulating arms; and a hinge assembly that includes two leaves, the anchor coupled to a first leaf of the two leaves, and a second leaf of the two leaves coupled to the driveshaft.
