Method and device for wearable contact lenses for remote optical monitoring of intraocular pressure

Abstract

A contact lens with a sensor region are described. The contact allows for normal vision and a concentric ring around the vision area of the lens includes one or more sensors for detecting changes in the interocular pressure of the eye. The data may be scanned using a camera, or in some embodiments, the data may be transmitted using a micro antenna in the sensing region. The data may be analyzed using a software application on a cell phone or other computing device.

Inventors: Dana; Aykutlu (Santa Clara, CA), Agaoglu; Sevda (Santa Clara, CA), Yazici; Ahmet Taylan (Santa Clara, CA), Ayas; Sencer (Santa Clara, CA), Baday; Murat (Santa Clara, CA), Komban; Savas (Santa Clara, CA)

Applicant: SmartLens, Inc. (Santa Clara, CA)

Family ID: 1000008765654

Assignee: SMARTLENS, INC. (Mountain View, CA)

Appl. No.: 17/344841

Filed: June 10, 2021

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS (1) This application is a continuation of PCT Application No. PCT/US19/66512, filed Dec. 16, 2019, which claims priority from U.S. Provisional Application 62/780,128 entitled “Method and Devices for Wearable Contact Lenses for Monitoring Interocular Pressure” filed Dec. 14, 2018, the contents of which are hereby incorporated by reference in their entirety.

BACKGROUND

Field

(1) The present disclosure relates to micromachined sensors. More particularly, the present disclosure relates to wearable microfluidic, optical, electronic and electromagnetic sensors for measuring the intraocular pressure (IOP) and corneal temperature.

Background

(2) Glaucoma is the second most common cause of blindness in the global world. It is a multifactorial disease with several risk factors, of which intraocular pressure (IOP) is the most important. IOP measurements are used for glaucoma diagnosis and patient monitoring. IOP has wide diurnal fluctuation, and is dependent on body posture and several other factors, so the occasional measurements done by the eye care expert in clinic can be insufficient and misleading. (3) Previously (US20160015265A1, 2018), an implantable microfluidic device has been proposed for intraocular pressure monitoring, that can be used for glaucoma diagnosis. Later, a wearable device was proposed (US2019/076021A1, 2019) to serve the same purpose, however without needing implantation.

BRIEF SUMMARY

(4) The present disclosure relates to a contact lens with a sensor for detecting changes in the intraocular pressure (IOP) of an eye. The sensor may utilize software technology in the form of a mobile device app to analyze the sensor data, which may be presented in visual, radio or thermal manner.

(5) In various embodiments, the contact lens may be formed from two polymer assemblies put together like a sandwich. The two polymer assemblies work cooperatively to form a single contact lens with IOP sensor. In other embodiments, various methods of making the molds used to make the contact lens with IOP sensor are described. In other embodiments, various forms of the IOP sensor are described, as well as other forms of sensors relating to the eye.

(6) In an embodiment, there may be a method of producing a planar mold. The method involves fabricating a planar substrate from a silicon material. Creating one or more reliefs on the planar surface wherein the reliefs will create one or more microfluidic channels in a membrane sheet.

(7) In an embodiment, there may be a method of producing a mold for use in the fabrication of a contact lens with a sensor. The method involves placing a liquid material on a planar mold, the liquid material being capable of changing from a liquid state to a substantially solid state. The planar mold may impart one or more microfluidic channels to the liquid material as the material transitions to the substantially solid state. The substantially solid state of the material forms a membrane sheet. Then centering a holder on to the membrane sheet, excising a portion of the membrane sheet, the portion of the membrane sheet having the microfluidic channels, the portion

of the membrane forming the membrane template. The membrane template is then clamped between the holder and a base assembly. The base assembly may have an aperture or a hole in the middle. The holder may be removed from the base assembly so the membrane template remains on the base assembly. The base assembly may then be pressed on to a curved mold, such that the membrane template is pressed against the curved mold. The base assembly aperture may then be filled with additional liquid material. The additional liquid material may be cured, and the resulting cured material forms a mold that has a curved surface that matches the curvature of the curved mold. The cured mold may be separated from the curved mold.

(8) In another embodiment, there may be a method of producing a curved mold for making a contact lens with a sensor, the method involves coating a curved mold with a photoresist and curing the photoresist. Then creating a predefined pattern in the photoresist. The pattern is developed and an elastomer is poured on top of the developed pattern. The photoresist is then cured to produce a mold.

(9) In another embodiment, there may be a method for producing a contact lens and sensor apparatus. The method involves forming a bottom membrane layer by coating a curved mold with a liquid elastomer and curing it. Then treating the bottom membrane layer with plasma to make the elastomeric surface hydrophilic and promote adhesion of a UV curable polymer. Then coating the elastomeric surface with a UV curable polymer, and imprinting microfluidic layers on the UV curable polymer using a mold. The method also involves as a separate process, making a top membrane layer by pouring elastomer on to a second curved mold, curing the top membrane layer and releasing the top membrane layer after curing it. Then performing a plasma treatment on the inside of the top membrane, coating the inside of the top membrane with UV curable polymer, and partially curing to solidify the UV curable polymer. Then placing the top membrane onto a pressurizing chamber, bonding the top and bottom membranes together to form a contact lens and sensor template and cutting the contact lens and sensor template to size. The cutting forms an abrupt edge on the contact lens, so a UV curable polymer is applied to the abrupt edge of the contact lens to form an atraumatic edge.

(10) In an embodiment, there may be an apparatus for measuring the intraocular pressure of an eye, the apparatus including an elastomeric contact lens body and a plurality of metallized Fabry-Perot optical interference cavities, the cavities distributed around the vision portion of the contact lens wherein changes of shape and reflected light cause changes in the contact lens' shape due to changes in intraocular pressure.

(11) In an embodiment, there may be an apparatus for measuring the intraocular pressure of an eye. The apparatus has an elastomeric contact lens body and a group of metallized cavities distributed in a sensor region of a contact lens body. The plurality of metallized cavities act as mechanically variable capacitors and resonating antennas within the contact lens and the group of metallized cavities change electromagnetic resonant response properties upon changes in intraocular pressure, by changing in capacitance or by changes in direct electrical contact between different parts of the antennas.

(12) In an embodiment, there may be an apparatus for measuring the intraocular pressure (IOP) of an eye. The apparatus may have an elastomeric contact lens body with a sensor region. There may be embedded transmission type gratings in the sensor region. The grating permitting external light into the posterior corneal cavity. Input and output coupling gratings route the external light, wherein the coupling condition on angle of incidence and wavelength of light can be used to calculate the strain exerted on the contact lens.

(13) In an embodiment, there may be an apparatus for measuring the intraocular pressure of an eye. The apparatus may have an elastomeric contact lens body having a sensor region. There may be fluorescent beads embedded into the sensor region.

(14) In an embodiment, there may be a system for determining changes in intraocular pressure over time. The system may include an elastomeric microfluidic contact lens with a sensor region.

Microfluidic channels may be dispersed within the sensor region. The channels may contain a density sensitive material capable of adhering to the microfluidic walls. The system may also have an optical reader for reading the changes in the density sensitive material, wherein the changes in density of the density sensitive material corresponds to changes in the intraocular pressure of the eye. Reading the optical density changes on the walls can be used to calculate intraocular pressure. The density sensitive material may be a dye, or fluorescent beads.

(15) In another embodiment, there may be an apparatus for measuring the intraocular pressure of an eye. The apparatus may have an elastomeric microfluidic contact lens with a sensor region. Liquid crystal thermometers may be embedded in the sensor region, wherein the liquid crystal thermometers change color due to corneal temperature changes.

Description

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

(1) To easily identify the discussion of any particular element or act, the most significant digit or digits in a reference number refer to the figure number in which that element is first introduced.

(46) FIG. **45** illustrates pressure sensor according to an embodiment **4500**.

(47) FIG. **46** illustrates pressure sensor according to an embodiment **4600**.

(48) FIG. **47** illustrates a sensing region with a “C” shaped sensing channel according to an embodiment **4700**.

DETAILED DESCRIPTION

(49) Described herein are various embodiments for a contact lens and IOP sensor, various molds and methods of making the same. The contact lens may be one that may be used for vision correction, cosmetic appearance or having no vision correction and no cosmetic effect. The portion of the contact lens that may lay over that portion of the eye a person (or animal) may see through may be visually transparent, and otherwise not interfere with the vision of the eye. This center portion of the device may be referred to as the vision area. The lens area may provide proper vision correction, aesthetic color or simply be transparent.

(50) In various embodiments, the sensor portion of the contact lens may have one or more elements embedded in the periphery of the contact lens. The periphery may be thought of as the annular space around the vision area of the contact lens. The periphery area may be thought of as the sensor area.

(51) The contact lens with sensor may be constructed in a variety of ways. In an embodiment, it may be possible to take an existing contact lens and add a sensor area around it. In another embodiment, it may be possible to construct a vision/aesthetic lens and a sensor area at the same time.

(52) Described herein are numerous embodiments for creating a top and bottom layer vision and sensor area and then putting the two layers together to form a single contact lens with sensor. In various embodiments, there may be a mold for the top layer and another mold for the bottom layer. Numerous methods of making the two molds as well as for making the two layers (top and bottom) are described herein.

(53) Various other embodiments are also presented on how the contact lens with sensor may have different sensors for detecting and measuring different aspects of the eye. Some embodiments measure IOP, some measure temperature changes, and still other embodiments measure the strain the eye may exert on the contact lens. Various devices may be used to collect the data from the sensors, and these devices include mobile phones, tablets, computers, and optical sensors. The optical information may be used in a program or app to provide a readily understandable and/or usable summary of the data collected to a user, health care provider, or other party.

(54) In an embodiment, there may be a planar substrate, such as a silicon wafer, a metal plate or a polymer sheet, as shown in FIG. 1. The planar substrate **100** may have a relief pattern **106** or negative mold suitable to create or form a microfluidic structure in the material used on the mold. The planar substrate **100** may have a planar mold **104** and a relief pattern **106**. The planar substrate may also have one or more flat edge **102** portions to facilitate use, handling or separation of the planar mold **104** from a material used with the planar mold **104**.

(55) In an embodiment, more than one mold may be present on the planar substrate. Although a single mold is shown, it should be understood that any number of molds may be made simultaneously on the same substrate.

(56) A process is now described for making a mold that may be used for fabricating a contact lens with an intraocular pressure sensor. The process involves generally placing a liquid material on to a planar mold. The liquid generally being a substance that can be deposited in liquid form, then changed somehow to be generally solid. As the material solidifies, it assumes the texture and form of the planar mold. The material may solidify into a membrane. A holder may be placed on the membrane, and a portion of the membrane may be excised around the holder. The holder may have a sticky or tacky surface so the excised portion of the membrane will adhere to the holder as the holder is moved. The holder may then be fastened to a base assembly with the membrane section between the holder and the base assembly. The fastening of the holder to the base assembly may allow the membrane to transfer onto the base assembly. The base assembly may then be pressed onto a curved mold in a manner that causes the membrane template to be stretched over the curved mold. The base assembly may have an aperture or fill port, allowing the back end of the base assembly to be filled with a material that will bind to the membrane template as it is stretched over the curved mold. The added material may then be cured so it solidifies. When the process is completed, the curved mold may be separated from the membrane template.

(57) The various stages of the process for making the curved mold are now described and illustrated in more detail. In an embodiment, there may be a planar substrate **212** having a planar mold **210** on one or both sides. The planar mold **210** may have a relief pattern **204**. A polymer or elastomeric material **206** may be deposited on the planar mold **210**. The planar mold **210** may be stationary or in rotation **202** while the material **206** is added to the planar mold **210**. The material **206** thickness may be controlled while rotation **202** of the planar mold **210** is underway. The speed of rotation may be controlled to choose an appropriate thickness of the material **206** as is well understood in the art.

(58) In various embodiments the planar substrate **212** may be rotated on a spindle or a platter or any other mechanism as is well understood in the art. The material may be added in a drop wise fashion or streamed onto the planar mold **210**. The method of adding the material **206** to the planar mold **210** may depend on the type of material, and the ability to control its deposition on the mold, or the adjustment of the material thickness while under rotation.

(59) Once the material is distributed on the planar mold **304**, it may be cured using energy **306**,

such as UV light, heat, or other forms of energy as are well understood in the art. The curing time may be done according to the manufacturing recommended time, or it may be less or more. The material when cured forms a substantially solid form. By substantially solid, applicant means the material may have regions of the cured material that may retain some fluidic properties. In some embodiments, the material may be partially cured. In an alternative embodiment, the material may be a substance that may be converted back into a liquid state, semi-liquid state or vapor state with the application of energy or chemical reagents. In some embodiments, the material may be an elastomeric compound.

(60) In some embodiments, the thickness of the membrane sheet **302** may vary between 1 to 999 microns (μm). In some embodiments the thickness of the membrane sheet **302** may vary between 25 to 600 microns. In still other embodiments, the membrane sheet **302** thickness may range from 50 to 500 microns.

(61) Once the membrane material is cured, a holder **402** may be placed on the membrane sheet. The holder may be circular or an annular ring. In some embodiments the footprint of the holder may be sized to be a specific diameter larger than the diameter of the microfluidic channels formed in the membrane sheet. In other embodiments the holder footprint may be sized to match the external diameter of the microfluidic channels. In some embodiments, where the shape of the microfluidics channels may not be regular, or not substantially circular, the holder may have a corresponding footprint of equal or larger size. In some embodiments where the holder may be an annular ring, the inner diameter of the annular ring may be sized such that the inner diameter exceeds the diameter of the microfluidics channels of the membrane sheet.

(62) In various embodiments, the holder **402** may have one or more holes **404**. The holes may be used to align holes of other parts for fastening the holder to another part to create an assembly. In some embodiments the holder may have an adhesive layer **406**. In an embodiment, the adhesive layer **406** may be double sided tape. In some embodiments the adhesive layer **406** may be a tacky material affixed to the holder **402**. In still other embodiments, the adhesive layer **406** may be a mechanical gripper, suction device or other temporary mechanical fastener.

(63) The process of making the curved mold may now proceed to centering the holder **504** on to the membrane sheet **502**. The tacky portion (not shown) of the holder **504** faces the membrane sheet **502** so the tacky portion may be in direct physical contact with the membrane sheet **502**. The holder **504** may be pressed on to the membrane sheet **502** following the placement direction **506** as shown. The aperture of the holder may be place around or on the microfluidic channels **508**.

(64) Once the holder is properly in place, the membrane template may be excised from the membrane sheet. An excise tool **602** may be used to create an excise path **606** around the holder **604**.

(65) In various embodiments, the excise tool **602** may be a knife, a laser, or any cutting tool or device (such as an energy device) that may be used to sever the membrane template from the membrane sheet. The excise tool **602** may follow a preprogrammed path, such as that created by a computer controlled cutting tool, or it may be a mechanical device on a cam following shaft. The membrane template may be cut manually as well.

(66) In some embodiments, the planar mold or planar substrate may be excised when the membrane is excised. In alternative embodiments, the excise path does not damage the planar mold or substrate. In those embodiments where the planar mold is undamaged, it may be reused.

(67) In an embodiment, there may be a base assembly **702**. The base assembly **702** may have one or more holes **706** in a pattern to match the holes of the holder, so that a fastener such as a screw may be used to fasten the holder to the base assembly **702**. The base assembly **702** may have a tacky or adhesive layer **704**. The adhesive layer may be similar to those previously described. The base assembly **702** may have an aperture such that it is shaped like a tube or hollow cylinder.

(68) The holder **802** with the membrane template **808** facing the base assembly **804**, may now be assembled. The holder **802** and base assembly **804** may be put together via connection **806** force,

with the various holes **810** aligned. The holes **810** may then receive fasteners such as screws, pegs, or glue. An adhesive **812** may be placed on the connection side of the base assembly **804** so the membrane template **808** may adhere to the base assembly **804** when the holder is separated from the combined base assembly **702**

(69) The membrane template **808** may be a uniform thickness with an aperture in the middle (inside the area defined by the microfluidics channels. In an alternative embodiment the membrane template is contiguous (having no aperture). In an embodiment, an annular ring of material may be used to create a sensor region that may be attached to a pre-existing contact lens.

(70) In some embodiments, the microfluidic channels may be oriented to face a particular direction. In other embodiments, other fixtures may have their orientation matched to the combined holder and base assembly.

(71) In various embodiments, the base assembly may be combined with a lower base assembly **904** as shown in FIG. **9**. The lower base assembly **904** may have a curved mold **902**. The curved mold **902** may be a hemisphere or sphere shaped mold, a partially curved mold of a particular radius and arch length or arch circumference. In some embodiments the curved mold **902** may be continuous in curvature to the seam between the curved mold **902** and the lower base assembly **904**.

(72) In various embodiments, the lower base assembly **904** may also have one or more fixture holes **906**. The fixture holes **906** may have the same shape an orientation as the holes in the base assembly, allowing the lower base assembly **904** and the base assembly to be fastened to each other using screws, pegs or other fasteners. While screws are envisioned as a possible embodiment, the various assembled portions (holder and base assembly, base assembly and lower base assembly) may be fastened using clamps, glue, clips or other mechanisms. The assembled portions may have an interference fit with one another, or a mechanical engagement such as one screwing on to the other.

(73) In various embodiments, the curved mold **902** may be made of glass, a non-stick material, or other surface that may cause the membrane template to stretch over the curved mold and assume substantially the same radius of curvature of the curved mold, without distorting the membrane template or the microfluidic channels to the point that either element cannot function.

(74) As previously described, various embodiments may assemble the base assembly with the lower base assembly as shown in FIG. **10**. In an embodiment, screws **1002** may be used as fasteners to secure the base assembly **1004** and lower base assembly **1008**. The base assembly **1004** may be in an orientation such that the membrane template faces the curved mold **1006** during assembly, so that the membrane template makes contact with the curved mold **1006**, and is stretched over the curved mold **1006** as the base and lower base assemblies are fastened together.

(75) In some embodiments, the membrane template may not be completely solidified or cured, so as to allow the membrane template to take the shape over the curved mold **1006** better.

(76) In an embodiment, the base assembly may have a cavity **1108** or an aperture behind the membrane template **1110** as shown in FIG. **11**. In an embodiment, the cavity **1108** may be back filled with additional material **1102** to partially or completely fill the cavity **1108** of the base assembly **1104**. The membrane template **1110** acts as a barrier, preventing the back filled material from contacting the lower base assembly **1106**.

(77) In an embodiment, a curing agent elastomeric material such as polydimethylsiloxane (or PDMS) may be applied on to the back surface of the membrane template **1110**. The elastomeric material may then be drained. Once the elastomeric material has been drained, the backside cavity **1108** may be filled with a premixed elastomeric material or equivalent material. A curing agent may improve the binding of the elastomeric material layer after curing.

(78) After material has been added into the cavity of the base assembly, it may be cured as shown in FIG. **12**. The base assembly **1202** and the lower base assembly **1204** may remain fastened while energy **1206** may be applied to the newly poured mold **1208** of material behind the membrane template **1210**. The energy may be any kind suitable to cure the material in the cavity of the base

assembly **1202**. Some non-limiting examples include ultraviolet (UV) light, heat, visible and non-visible light energy, or other materials, such as a chemical curing agent. The assembled base and lower base combination may be placed in a chamber, such as an oven or light chamber, for the curing process. While in an embodiment, the energy **1206** is shown radiating from a single direction, it should be understood that the energy may originate from one or more point sources, or may originate from an energy source, and indirectly reach the mold **1208** to cure it, as in the case of an oven chamber.

(79) A cross section of the mold **1302** formed in the base assembly **1304** and the membrane template **1306** are shown in FIG. **13**. The mold **1302** may be separate from the lower base assembly, and may be used in the imprinting process for making contact lens and IOP sensing devices.

(80) An alternative method of making a contact lens and IOP sensor mold is now described. In various embodiments, there may be a curved mold that may be coated with a photoresist. The photoresist may then be cured for a period of time. The cure time may be more, less or equal to the amount of time normally used for a photoresist material. When the photoresist has reached a suitable cure state, a pattern may be created in the surface of the photoresist, and the pattern may be developed to produce one or more reliefs or other features for the creation of microfluidic channels. An elastomeric compound may then be poured over the patterned surface and cured to produce a contact lens and IOP sensor mold.

(81) In an embodiment, a bottom membrane layer may be fabricated by drop casting **1406** a thin layer of an elastomeric material **1402** (such as premixed PDMS) onto a curved mold **1408** as shown in FIG. **14**. The curved mold **1408** may sit or be affixed to a lower base assembly **1404**. The curved mold may be a glass hemisphere, sphere or other suitable material. The elastomeric material may be a photoresist material.

(82) In an embodiment, the Elastomeric membrane **1502** may be cured by the application of energy **1504**. In various embodiments, the energy **1504** may be thermal energy (heat), UV light, or other curing energies. In some alternative embodiments, the Elastomeric membrane **1502** may be cured by exposing it to a curing compound. The elastomeric membrane **1502** thickness may be controlled by the composition of the material used for the membrane, the viscosity or a spinning process prior to curing.

(83) In an embodiment, the elastomeric layer may be treated with plasma **1602** to improve bonding of subsequent UV curable polymer layers. The lower base assembly **1606** with the curved mold serves as the substrate for the membrane and photoresist layer **1604** during plasma **1602** treatment. The plasma **1602** may be used to create a pattern in the photoresist.

(84) In an embodiment, an elastomeric compound **1702** may be drop cast **1712** to form a PDMS membrane **1714** (or other suitable material) as shown in FIG. **17**. The PDMS may be drop cast **1712** on a curable polymer layer **1704** with another membrane **1706** layer underneath. The lower base assembly **1708** may be rotated in either direction as the curable elastomeric compound **1702** is spin coated **1710** on the curable polymer layer **1704**.

(85) In some embodiments, the PDMS membrane **1714** may be between 0.01 microns and 999 microns. In some embodiments, the PDMS membrane **1714** may be between 1 and 300 microns. In still other embodiments the membrane may be between 10-50 microns.

(86) In an embodiment, a curable polymer layer **1804** may be cured using UV light **1810** projected through an aperture **1812** of the lower base assembly **1808**. The UV light **1810** may shine through a membrane **1802** and a curved mold **1806** (which may be partially or mostly transparent to the UV light). When the curing process is completed, the mold may be finished.

(87) In an embodiment, there may be a thin bottom PDMS membrane **1910** with a partially cured UV curable polymer layer **1906** which may be drop cast **1908** by applicator to form a second layer **1904** of a UV curable polymer as shown in FIG. **19**. In an embodiment, the membrane **1910** may have a base elastomer **1902** layer, a first UV curable polymer layer **1906** and a second layer **1904**

of UV curable polymer. The membrane **1910** may be formed on a curved mold supported by a base assembly **1912**.

(88) In an embodiment a curved mold **2004** may be brought into contact with an assembly previously described and a controlled pressure **2002** may be applied to perform the imprinting step as shown in FIG. **20**. The layer **2006** may be cured partially by UV light **2008**, while the two components are in contact.

(89) In an embodiment, a PDMS patternless membrane **2106**, prepared as previously described, may be peeled from the curved mold **2102** which may be supported by a base assembly **2104** as shown in FIG. **21**.

(90) In an embodiment, a PDMS membrane **2204** may be flipped upside down and placed on a cylindrical holder **2206** as shown in FIG. **22**. The upside-down membrane **2204** may be pressed into the holder **2206** using suitable force **2202**.

(91) In an embodiment, the concave side the PDMS membrane **2304** may be exposed to plasma **2302** to promote adhesion of UV curable polymer layers as shown in FIG. **23**. The membrane **2304** may be held in place by a membrane holder **2306**.

(92) In an embodiment, an applicator may be used to drop cast a UV curable resin **2402** in to the concave side of the curved membrane **2304** as shown in FIG. **24**. The membrane holder **2406** may be rotated **2408** to spin coat the resin on the membrane.

(93) In an embodiment, there may be a pressure cap **2504**, with a gas port **2502** and a window **2512** as shown in FIG. **25**. The window **2512** may be transparent to UV light and/or other forms of optical energy. The membrane **2508** may be attached to a holder **2510**. The membrane may have a partially cured UV curable resin layer **2506**.

(94) In an embodiment, a retaining ring **2602** may be attached from the top side of the assembly in FIG. **25** to hermetically seal the pressure chamber and hold the PDMS membrane **2604** in place as shown in FIG. **26**. The retaining ring **2602** may hold the membrane **2604** in place generally without causing in plane strain that may cause deformation of the membrane. The UV curable resin may be lightly cured using the UV light **2606** to maintain partial adhesive properties.

(95) In an embodiment, the two assemblies of the device with the top membrane **2702** and the bottom membrane **2704** may be brought into contact with the application of pressure **2706**, as shown in FIG. **27**.

(96) In an embodiment, the top layer **2802** and bottom layer **2804** may be bonded together using UV light **2806** as shown in FIG. **28**. Pressure **2808** may be applied to the two layers while the UV bonding is done.

(97) In an embodiment, the contact lens with IOP sensor **2906** may be exposed by removing the top mold assembly as shown in FIG. **29**. Exposure of the contact lens with IOP sensor **2906** may allow for a punch cutter **2904** to be centered over the lens. The application of force **2902** may cut the contact lens with IOP sensor **2906** away from the curved mold assembly **2908**.

(98) In another embodiment, after bonding, the top mold may be removed to allow access of a cylindrical punch cutter. The assembled lens may be cut using the punch and removed from the curved mold. The lens may then be filled with detection fluid and made hydrophilic and may be ready to use.

(99) We now go on to describe various methods of measuring the intraocular pressure based on optical changes in metal-insulator-metal type cavities upon strain.

(100) An example model of the strain distribution of an elastomeric contact lens is shown in FIG. **30**. As can be seen in the figure, a Von Mises Stress pattern is shown with a scale of the stress on the left of the image. The image is a computer-generated image of an actual contact lens according to an embodiment. The strain can be seen near the edges of the contact lens.

(101) In various embodiments, a variety of stress situations may be demonstrated as shown in FIG. **31**. A cross section of a free **3102** cavity lens is shown at the top of the drawing page. In another embodiment, a stressed **3104** cavity pattern is shown in the middle. The bottom illustrates a

stressed to collapsed **3106** cavity.

(102) In an embodiment, a cross section of a metallized elastomeric rectangular cavity is shown. The cavity **3202** may be coated or surrounded by thin metal film **3206** strips sandwiched between elastomeric layers **3204**. This design forms an interferometric structure whose optical properties depend sensitively on the deformation of the cavity.

(103) An alternate view of the thin metal film is shown in FIG. **33**. In an embodiment, a cavity **3310** is surrounded by a pattern metal film **3302** and a thin metal film **3306**. The two metal films may be sandwiched between a pair of elastomeric layers **3304**. The pattern metal film **3302** may be a nanoscale patterned metal film. The pattern may help tune the optical properties such as optical resonances and angular response. Periodic or quasi periodic metal patterns with characteristic dimensions ranging from 1 nanometer to 10 micrometers may be used. The size and patterns of the structures may be optimized for improving the optical response at a specific wavelength and angular incidence.

(104) In an embodiment, the cross section of a metallized elastomeric rectangular cavity and deformation under applied stress is shown in FIG. **34**. The stress vectors are shown in the horizontal plane, causing the cavity to be pulled to the sides and to compress along the top and bottom. The elastomeric layers provide a flexible medium that may tolerate the various stress and strain forces without compromising the material. The arrows up and down illustrate the vectors of light waves entering and exiting the lens in order to read the level of force, stress or strain on the contact lens.

(105) A cross section of an embodiment of the contact lens is shown in FIG. **35**. In an embodiment, the contact lens **3506** has a viewing region **3502** and a sensing region **3504**. The viewing region may be generally clear and substantially free from microfluidic structures, sensors or other elements that may adversely affect vision. The sensing region **3504** may contain the sensors that respond to changes in the TOP of the eye, sensors that detect stress or strain based on the shape of the eye and so on.

(106) In an embodiment, there may be metal insulator metal (MIM) cavities in the sensing region **3504**. The MIM cavities may detect changes in the TOP of the eye, and change shape in response to the changes in IOP. The shape changes may advance or withdraw the fluid-air interface in the micro microfluidic channels, which can be read by an optical sensor.

(107) In another embodiment, there may be a metallization procedure for the contact lens with IOP sensors as shown in FIG. **36**. In an embodiment, a lower base assembly **3608** may hold a curved mold **3604**. The curved mold may have a bottom membrane **3606**, a UV curable layer **3614** and a metal layer **3612** as shown. Metal deposition **3602** may occur through a shadow mask **3610** to deposit metal on the metal layer **3612**. In some embodiments, the deposition may be done by evaporation or sputtering. In other embodiments, the metal layer may be placed on the membrane without a shadow mask **3610**, and instead it may be EDM (electrical discharge machining) or micro machined to a particular pattern.

(108) In various embodiments, the bottom membrane **3606**, and the UV curable layer **3614** may be any similarly described layer herein.

(109) In an embodiment, the assembly of the various layers is shown in FIG. **37**. In an embodiment, a holder **3704** may have a pressurizing cap **3702** with an air access hole **3714**. The top membrane **3706** may have a UV curable resin layer **3708** and a metal layer **3718**. The lower base assembly **3712** may have a thin bottom membrane **3710** that may include a second metal layer **3720**, a UC UV curable layer **3722** and a bottom membrane **3724**. The thin bottom membrane **3710** composition may sit on a curved mold on the lower base assembly **3712**. The top and bottom membranes may be pressed together and bonded to form into an elastomeric contact lens with optical strain sensors.

(110) In an embodiment the contact lens **3810** may have a series metallization cavities **3802**. A cross section is shown with the metallization layer **3808**, the metallization cavity **3806** and the

contact lens **3810**. In this embodiment, the strain caused by a change in the IOP of the eye may perturb the cavities and modify the electromagnetic resonances of the ring shaped metallization cavity **3802**, causing the rings to act as remote sensing antennas. In an embodiment, the lenses may sense intraocular pressure through a remote radio frequency measurement, similar to the readout of an RF-ID chip.

(111) In another embodiment, the contact lens **3902** may have metallized metalized regions **3904** with cavities **3906** as shown in FIG. **39**. Changes in the TOP of the eye may cause strain to perturb the cavities **3906**. The alteration of the cavities may modify the electromagnetic resonances of the metalized regions **3904** to act as remote sensing antennas. In this embodiment, the lenses may be used to sense changes in intraocular pressure through remote radio frequency resonance measurement, similar to the readout of a RFID chip.

(112) In an embodiment, a cross section of the metallized metalized regions **3904** is shown. The cross section shows a single cavity **3910** and the metallization layer **3908** on two of the cavity sides. The cavity is imbedded in the contact lens **3912**. While this embodiment shows two sides of the cavity with metallization layers, it should be understood that the cavity may have anywhere from 1-4 sides with metallization layers. The cavity may not be a regular polygon, and may have a circular cross section. In such instances the cavity may have any portion of the circumference of the cross section metallized to achieve a similar result as described herein.

(113) In still another embodiment, there is an alternative method of making the curved mold **4002** as shown in FIG. **40**. In an embodiment, the curved mold **4002** may be coated with a photoresist **4006**. A laser projection system **4012** may be used to define by UV exposure **4010**, the microfluidic channel patterns **4008** directly onto the curved mold **4002** with photoresist **4006**.

(114) In some embodiments, the polymer layer may be made from a photodefinable polymer like SU8. The microfluidic channels may form in concentric rings, a “C” ring around the sensor region with switch back corners to provide continuous channels going around the periphery.

(115) In some embodiments, the microfluidics sensor may use an air reservoir. The height of the air reservoir may be from 1 micron to 1 mm. In some other embodiments the air reservoir height may be from 5 to 500 microns. In still other embodiments, the height of the air reservoir may be from 10 to 200 microns.

(116) In some embodiments, an air reservoir may also be provided. In some embodiments, the air reservoir may have a width of 1 μm to 10 mm. In another embodiment the width may be 10 microns to 1 mm. In still other embodiments, the width of the air reservoir may be between about 30 microns to 200 microns.

(117) In some embodiments, the number of liquid reservoir channels may be between about 1 to 1,000,000. In some other embodiments the number of liquid reservoir channels may be between about 1 to 100. In still other embodiments the number of liquid reservoir channels may be about 1 to 20.

(118) In another embodiment for making the mold, the top side of the curved mold **4110** with microfluidics patterns **4102** may be turned into a mold by filling the top aperture of the holder **4104** with an elastomer **4106**. The cylindrical housing **4108** contains the elastomer **4106** which may be cured. The curved mold **4110** may be attached to a lower base assembly **4112**.

(119) An alternative method and device for measuring IOP may be seen in an embodiment shown in FIG. **42**. In this embodiment, light entering **4210** the eye may pass through a contact lens **4202** resting on the cornea **4208**. Some light entering **4210** passes through transmission type grating for the input light **4212** and output light **4206**. The input light **4212** diffracts internally, passing through the cornea **4208** or posterior corneal cavity (beyond the iris), and may be outcoupled back as output signal or light exiting **4204** the eye. The light exiting **4204** may be imaged using a regular color or spectrally resolved camera system for intensity and position to extract strain related perturbations in the lens and cornea.

(120) In still another embodiment, a contact lens **4302** may have one or more microfluidics features

4304 and embedded liquid crystal patterns **4306** as shown in FIG. **43**. In some embodiments, the embedded liquid crystal patterns **4306** may produce color palettes that may be detected by a camera, such as those on a cell phone or tablet. The color palettes may be read and compared to an optical thermometer array **4308**. The liquid crystal optical thermometer array **4308** can be used to measure temperature based on different spots having varying color transition temperatures. The contact lens **4302** with microfluidics features **4304** or other optical features may now supplement for independent temperature measurement by using the embedded liquid crystal patterns **4306**. A picture of the lens may yield the device temperature.

(121) In another embodiment, an alternative feature for the contact lens is shown in FIG. **44**. In an embodiment, a solution may be mixed with beads or dyes that have low binding affinity. As the eye pressure changes throughout the day, dyes may bind to the channel walls where the solution resides. The longer the walls of the channels may be exposed to the dye, the darker or more intense the color stain on the walls. Based on dwell time, highest, average and standard deviations of the eye pressure may be calculated from the color correlation map (shown with the spectrum from dark to light).

(122) In yet another embodiment, an additional feature for a contact lens with a sensor is shown in FIG. **45**. In an embodiment, the lens' micro channels may be filled with red dyes (or beads). The red dye (or bead) may be withdrawn after an incubation period. The dyes may leave red residue through the channel with the dyes bound to channel walls. Later, a solution with blue dyes may be loaded to the channel for eye pressure measurement. An imaging method may be used to retrieve color correlation through the channel for red and blue colors. Using a correlation algorithm, it may be possible to calculate the highest, average, and standard deviations of the eye pressure throughout the day and night.

(123) In another embodiment, beads may be embedded in the contact lens, as shown in FIG. **46**. The fluorescent beads may have a diameter between 10 nm to 1 mm. In some embodiments the diameter may be 1 to 250 microns. In still other embodiments the diameter of the beads may be between 20 to 100 microns. The beads may be placed in the contact lens. The contact lens may be made of a transparent elastic material. The beads may be localized with various imaging techniques using an excitation source such as a UV or Blue or Green LED light and using a camera with an emission band pass filter, or a smartphone adapter having the same. Beads may be located with high accuracy by fitting point-spread-functions to 2-D gaussian functions and distances between the beads may be determined with micrometer accuracy using such data processing. As the eye pressure changes, the lens may be extended or compressed, and the beads' relative positions may change due to the changes in the curvature of the eye. The strain on the contact lens may be determined for each bead pair and overall pressure change may be accurately calculated.

(124) In some embodiments, the distance between beads may be between 1 micron to 10 cm. In another embodiment the distance between beads may be between 10 microns and 1 mm. In still another embodiment, the distance between beads may be between 50 to 500 microns.

(125) In an embodiment, a C-shaped sensing channel **4704** may be used in place of one or more annular ring channels as shown in FIG. **47**. The sensing channel **4704** may have a fill port for adding liquid, and a reporting channel **4702** for indicating the level of intraocular pressure the eye is experiencing. An air reservoir **4706** provides the air to form the gas-air interface in the microfluidics channel **4710**. A scale **4712** may be present on the sensing region. In an embodiment, the scale may be viewed using a camera, such as on a cell phone, and the image may show the level of IOP according to the location of the liquid-gas interface on the microfluidics channel **4710**.

(126) The advantages of the present disclosure include, without limitation, a robust process for making of highly sensitive wearable contact lens sensors that require no electrical power or circuits and can be monitored remotely by a simple camera like one found in a mobile phone.

(127) Various aspects of the disclosure are now provided: 1. A method aspect of producing a planar mold, the method comprising: fabricating a planar substrate from a material; and creating one or

more reliefs on the planar substrate wherein the one or more reliefs will create one or more microfluidic channels in a membrane sheet; and wherein the material is optionally made from silicon or a silicon composite. 2. A method aspect of producing a mold for use in the fabrication of a contact lens sensor, the method comprising: placing a liquid material on a planar mold, the liquid material being capable of changing from a liquid state to a substantially solid state, wherein the planar mold will impart one or more microfluidic channels to the liquid material as the material transitions to the substantially solid state, the substantially solid state of the material forming a membrane sheet; centering a holder on to the membrane sheet; excising a portion of the membrane sheet, the portion of the membrane sheet having the microfluidic channels, the portion of the membrane being a membrane template; clamping the membrane template between the holder and a base assembly, the base assembly having an aperture; removing the holder from the base assembly such that the membrane template remains on the base assembly; pressing the base assembly to a curved mold, such that the membrane template is pressed against the curved mold; filling at least a portion of the base assembly aperture with additional liquid material; curing the liquid material so the liquid material has a curve matching the curved mold; and separating the curved mold from the membrane template. 3. The method of aspect 2, wherein the transition of the liquid material to a substantially solid state involves curing the material for a period of time. 4. The method of aspect 2, wherein the liquid material is a polymer. 5. The method of aspect 2, wherein the liquid material is an elastomeric substance. 6. The method of aspect 2, wherein the method is a lithographic process. 7. The method of aspect 2, wherein one or both of the holder and the base assembly are configured in a substantially tube shape. 8. The method of aspect 7, wherein one or both of the holder and base assembly are substantially cylindrical. 9. The method of aspect 2, wherein one or both of the holder and the base assembly are an annular ring. 10. The method of aspect 2, wherein the membrane template substantially matches a footprint of the holder. 11. The method of aspect 2, wherein the excising of the membrane template is done with a laser. 12. A method aspect of producing a mold for a contact lens with a sensor, the method comprising: coating a curved mold with a photoresist; curing the photoresist; creating a predefined pattern in the photoresist; developing a patterned surface in the photoresist; and pouring an elastomer on top of the predefined pattern surface; and curing the photoresist to produce the mold. 13. A method aspect for the production of a sensor and lens apparatus, the method comprising: forming a bottom membrane layer by coating a curved mold with a liquid elastomer; curing the bottom membrane layer; treating the bottom membrane layer with plasma to make an elastomeric surface hydrophilic and promote adhesion of a UV curable polymer; coating the bottom membrane with a UV curable polymer; imprinting a microfluidic layers on the UV curable polymer using an etched mold; making a top membrane layer by pouring elastomer on to a second curved mold; curing the top membrane layer; releasing the top membrane layer after curing; performing a plasma treatment on the inside of the top membrane; coating the inside of the top membrane with UV curable polymer, and partially curing to solidify the UV curable polymer; placing the top membrane onto a pressurizing chamber; bonding the top and bottom membranes together to form a contact lens and sensor template; cutting the contact lens and sensor template to size, the cutting forming an abrupt edge on the contact lens; and applying a UV curable polymer to the abrupt edge of the contact lens to form an atraumatic edge. 14. The method of aspect 13, wherein the making of a hydrophilic elastomeric surface further comprises curing the surface with a UV curable polymer from a backside. 15. The method of aspect 13, where in the coating is done by spinning the mold as the material is added on to the mold, or layers of polymer on the mold. 16. An apparatus aspect for measuring the intraocular pressure of an eye, the apparatus comprising: an elastomeric contact lens body with a sensor region; and a plurality of metallized Fabry-Perot optical interference cavities, the cavities distributed in the sensor region; wherein changes of shape and reflected light cause changes in the contact lens' shape due to changes in intraocular pressure. 17. The apparatus of aspect 16, wherein the changes in the contact lens shape may be sensed remotely. 18. The apparatus of aspect 16, wherein the changes in

the contact lens shape may be sensed indirectly. 19. An apparatus aspect for measuring the intraocular pressure of an eye, the apparatus comprising: an elastomeric contact lens body with a sensor region; and a plurality of metallized cavities distributed in a sensor region of the contact lens body; wherein the plurality of metallized cavities act as mechanically variable capacitors and resonating antennas within the contact lens; wherein the plurality of metallized cavities change electromagnetic resonant response properties upon changes in intraocular pressure, by changing in capacitance or by changes in direct electrical contact between different parts of the antennas. 20. The apparatus of aspect 19, wherein the intraocular pressure of an eye may be sensed remotely. 21. The apparatus of aspect 19, wherein the intraocular pressure of an eye may be sensed indirectly. 22. An apparatus aspect for measuring the intraocular pressure (IOP) of an eye, the apparatus comprising: an elastomeric contact lens body with a sensor region; a plurality of embedded transmission type gratings, the grating permitting external light into the posterior corneal cavity; a plurality of input and output coupling gratings for routing of the external light; wherein the coupling condition on angle of incidence and wavelength of light can be used to calculate the strain exerted on the contact lens. 23. The apparatus of aspect 22, wherein the strain exerted on the contact lens may be used to determine the corneal deformation due to intraocular pressure. 24. An apparatus aspect for measuring the intraocular pressure of an eye, the apparatus comprising: an elastomeric contact lens body having a sensor region; and a plurality of fluorescent beads embedded into the sensor region. 25. The apparatus of aspect 24, wherein the plurality of fluorescent beads are sized between $0.01\text{ }\mu\text{m}$ to $600\text{ }\mu\text{m}$ in diameter. 26. The apparatus of aspect 24, wherein the plurality of fluorescent beads are sized between $0.1\text{ }\mu\text{m}$ and $400\text{ }\mu\text{m}$. 27. The apparatus of aspect 24, wherein the plurality of fluorescent beads are scattered in the contact lens with an average distance between the fluorescent beads of $1\text{ }\mu\text{m}$ to 10 mm . 28. The apparatus of aspect 24, wherein the separation of the plurality of fluorescent beads changes based on changes in the intraocular pressure of the eye. 29. The apparatus of aspect 28, wherein the separation of the fluorescent beads is determined by a mobile phone app on a mobile phone with a camera. 30. A system aspect for determining changes in intraocular pressure over time, the system comprising: an elastomeric contact lens with a sensor region; and a plurality of microfluidic channels dispersed within the sensor region, the channels containing a density sensitive material capable of adhering to the microfluidic walls; and an optical reader for reading the changes in the density sensitive material; wherein the changes in density of the density sensitive material corresponds to changes in the intraocular pressure of the eye; and wherein reading the optical density changes on the walls can be used to calculate intraocular pressure. 31. The system of aspect 30, wherein the density sensitive material is a dye. 32. The system of aspect 30, wherein the density sensitive material is a bead. 33. The system of aspect 30, wherein the optical reader is a mobile phone. 34. The system of aspect 30, wherein the density sensitive material is absorbed into the surface of the microfluidic channels. 35. The system of aspect 34, wherein the density sensitive absorption by the microfluidic channels corresponds to changes in intraocular pressure. 36. An apparatus aspect for measuring the intraocular pressure of an eye, the apparatus comprising: an elastomeric contact lens with a sensor region; and a plurality of liquid crystal thermometers embedded in the sensor region; wherein the liquid crystal thermometers change color due to corneal temperature changes. 37. The apparatus of aspect 36, wherein the color can be detected remotely. 38. The apparatus of aspect 36, wherein the color can be detected indirectly.

Claims

1. A method for the production of a contact lens and sensor apparatus, the method comprising: forming a bottom membrane layer by coating a curved mold with a liquid elastomer; curing the bottom membrane layer; treating the bottom membrane layer with plasma to make an elastomeric surface hydrophilic and promote adhesion of a first UV curable or heat curable polymer; coating

the bottom membrane layer with the first UV curable or heat curable polymer; imprinting at least one microfluidic layer on the first UV curable or heat curable polymer using an etched mold; making a top membrane layer by pouring elastomer on to a second curved mold; curing the top membrane layer; releasing the top membrane layer after curing; performing a plasma treatment on the inside of the top membrane layer; coating an inside of the top membrane layer with the first UV curable or heat curable polymer, and partially curing to solidify the first UV curable or heat curable polymer; placing the top membrane layer onto a pressurizing chamber; bonding the top and bottom membrane layers together to form a contact lens and sensor template; cutting the contact lens and sensor template to size, the cutting forming an abrupt edge on the contact lens; and applying a second UV curable or heat curable polymer to the abrupt edge of the contact lens to form an atraumatic edge.

2. The method of claim 1, wherein the making of the hydrophilic elastomeric surface further comprises curing the surface with a third UV curable or heat curable from a backside.
 3. The method of claim 2, wherein the third UV curable or heat curable polymer comprises a different UV curable or heat curable polymer than the first UV curable or heat curable polymer and the second UV curable or heat curable polymer.
 4. The method of claim 1, wherein coating the bottom membrane layer is done by spinning the curved mold as the first UV curable or heat curable polymer is added onto the curved mold, or wherein coating the inside of the top membrane layer is done by spinning the second curved mold as the first UV curable or heat curable polymer is added onto the second curved mold.
 5. The method of claim 1, further comprising: adding a solution into the microfluidic layer, the solution mixed with beads or dyes with a low binding affinity.
 6. The method of claim 4, where in the beads are fluorescent beads having a diameter between 10 nm up to 1 mm.
 7. The method of claim 6, wherein the fluorescent beads are between 0.01 μm to 600 μm in diameter.
 8. The method of claim 5, wherein adding a solution into the microfluidic layer comprises adding a first color solution mixed with beads or dyes; and adding a second color solution with dyes.
 9. The method of claim 8, further comprising retrieving a color correlation of the first color solution and the second color solution via imaging.
 10. The method of claim 9, further comprising calculating one or more of a high, average, or standard deviation of an eye pressure throughout a 24 hour cycle via a correlation algorithm.
 11. The method of claim 5, further comprising imaging the beads via one or more of UV light, blue LED light, or green LED light.
 12. The method of claim 11, wherein imaging comprises imaging using an emission band pass filter with one or more of a camera or a smartphone adapter.
 13. The method of claim 5, further comprising locating the beads by fitting point-spread-functions to 2-D gaussian functions.
 14. The method of claim 1, further comprising: arranging a sensor region around a viewing region of the contact lens.
 15. The method of claim 1, wherein the imprinting of the at least one microfluidic layer further comprises: imprinting a liquid reservoir and an air reservoir.
 16. The method of claim 1, wherein the first UV curable or heat curable polymer and the second UV curable or heat curable polymer comprise different UV curable or heat curable polymers.
