MASSAGE MECHANISM AND MASSAGER

Abstract

A massage mechanism and a massager are provided. The massage mechanism includes a housing, a driving motor, two eccentric wheels, two swing rods, and two massage heads. Each swing rod has a first end and a second end opposite to the first end in a length direction of the swing rod. Second ends of the two swing rods are respectively received in two elongated slots to allow each second end to linearly reciprocate and limit motion of each second end. In a process of **360°** rotation of the first end of each swing rod around the central axis of each eccentric wheel under the drive of each eccentric wheel, the two massage heads are close to or away from each other, and are configured to perform a yaw motion around a rotation axis parallel to the central axis of each of the two eccentric wheels in a preset angle range.

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority under 35 U.S.C. § 119 (a) to Chinese Patent Application No. 202410187841.1, filed on Feb. 19, 2024, and Chinese Patent Application No. 202420307072.X, filed on Feb. 19, 2024, the entire disclosures of which are incorporated herein by reference.

TECHNICAL FIELD

[0002] This disclosure relates to the field of massage device technology, and in particular to a massage mechanism and a massager.

BACKGROUND

[0003] With continuous improvement of living standards, more and more people begin to pay attention to their own physical health. When people feel physically sick, such as backache, neck and shoulder pain, leg pain, or the like, people use massagers to massage their own bones, tendons, and muscles in order to relieve fatigue, treat, or prevent pain.

SUMMARY

[0004] In a first aspect, a massage mechanism is provided in embodiments of the present disclose. The massage mechanism includes a housing, a driving motor, two eccentric wheels, two swing rods, and two massage heads. The housing is provided with two elongated slots. The driving motor is fixedly disposed at the housing. The two eccentric wheels are disposed at the housing. The two eccentric wheels are in transmission connection with the driving motor to rotate under the drive of the driving motor. Each of the two eccentric wheels is provided with an eccentric connection portion. The eccentric connection portion is spaced apart from a central axis of each of the two eccentric wheels. The two swing rods are symmetrically arranged. Each of the two swing rods has a first end and a second end opposite to the first end in a length direction of each of the two swing rods. The first end is hinged to the eccentric connection portion to rotate 360° around the central axis of each of the two eccentric wheels along with the eccentric connection portion. Second ends of the two swing rods are respectively received in the two elongated slots to allow each of the second ends to linearly reciprocate and limit motion of each of the second ends in a direction perpendicular to the length direction of each of the two swing rods. The two massage heads extend out of the housing and is configured to massage a target massage area. The two massage heads are fixedly connected to the second ends of the two swing rods respectively. In a process of 360° rotation of the first end of each of the two swing rods around the central axis of each of the two eccentric wheels under the drive of each of two eccentric wheels, the two massage heads are close to or away from each other, and each are configured to perform a yaw motion around a rotation axis parallel to the central axis of each of the two eccentric wheels in a preset angle range.

[0005] In a second aspect, a massager is provided in embodiments of the present disclosure. The massager includes a massage mechanism. The massage mechanism includes a housing, a driving motor, two eccentric wheels, two swing rods, and two massage heads. The housing is provided with two elongated slots. The driving motor is fixedly disposed at the housing. The two eccentric wheels are disposed at the housing. The two eccentric wheels are in transmission connection with the driving motor to rotate under the drive of the driving motor. Each of the two eccentric wheels is provided with an eccentric connection portion. The eccentric connection portion is spaced apart from a central axis of each of the two eccentric wheels. The two swing rods are symmetrically

arranged. Each of the two swing rods has a first end and a second end opposite to the first end in a length direction of each of the two swing rods. The first end is hinged to the eccentric connection portion to rotate 360° around the central axis of each of the two eccentric wheels along with the eccentric connection portion. Second ends of the two swing rods are respectively received in the two elongated slots to allow each of the second ends to linearly reciprocate and limit motion of each of the second ends in a direction perpendicular to the length direction of each of the two swing rods. The two massage heads extend out of the housing and is configured to massage a target massage area. The two massage heads are fixedly connected to the second ends of the two swing rods respectively. In a process of 360° rotation of the first end of each of the two swing rods around the central axis of each of the two eccentric wheels under the drive of each of two eccentric wheels, the two massage heads are close to or away from each other, and each are configured to perform a yaw motion around a rotation axis parallel to the central axis of each of the two eccentric wheels in a preset angle range.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

[0006] To describe the technical solutions in embodiments of the present disclosure or in related art more clearly, the following briefly introduces the accompanying drawings required for describing the embodiments or the related art. Apparently, the accompanying drawings in the following description show merely some embodiments of the present disclosure. For those of ordinary skill in the art, other accompanying drawings may also be obtained according to structures shown in these accompanying drawings without creative efforts.

[0007] FIG. 1 is a schematic structural view of an exterior of a housing of a massage mechanism according to some embodiments of the present disclosure.

[0008] FIG. 2 is a schematic structural view of an interior of a housing of a massage mechanism according to some embodiments of the present disclosure.

[0009] FIG. 3 is a schematic structural view of an exterior of a housing of a massage mechanism according to some embodiments of the present disclosure.

[0010] FIG. 4 is a schematic structural view of an eccentric wheel of a massage mechanism according to some embodiments of the present disclosure.

[0011] FIG. 5 is a schematic structural view of a swing rod of a massage mechanism according to some embodiments of the present disclosure.

[0012] FIG. 6 is a schematic structural view of a massage mechanism with two through holes defined on a housing surface according to some embodiments of the present disclosure.

[0013] FIG. 7 is a schematic structural view of two swing rod covering a cover plate of a massage mechanism according to some embodiments of the present disclosure.

[0014] FIG. 8 is a schematic structural view of a flexible housing of a massage mechanism according to some embodiments of the present disclosure.

[0015] FIG. 9 is a schematic structural view of a housing surface of a massage mechanism according to some embodiments of the present disclosure.

[0016] FIG. 10 is a structural schematic view of a massager according to some embodiments of the present disclosure.

[0017] Reference signs in the accompanying drawings are described as follows: massage mechanism 100, housing 10, elongated slot 11, rib 111, rib top-surface 1111, oil storage groove 112, oil storage hole 113, housing surface 12, through hole 121, recess 122, driving motor 20, eccentric wheel 30, eccentric connection portion 31, cam surface 32, swing rod 40, first end 41, second end 42, first connection arm 43, second connection arm 44, extension portion 441, reinforcing structure 45, first reinforcing structure 451, second reinforcing structure 452, massage head 50, first massage

head **51**, second massage head **52**, cover plate **60**, elongated hole **61**, flexible housing **70**, opening hole **71**, massage housing **80**, first housing part **81**, second housing part **82**, massager **200**.

DETAILED DESCRIPTION

[0018] Embodiments of the present disclosure are described in detail below. Examples of the embodiments are illustrated in the accompanying drawings, in which the same or similar reference signs denote the same or similar elements or the elements having the same or similar functions throughout. The embodiments described below by reference to the accompanying drawings are exemplary, are only used to explain the present disclosure, and cannot be understood as a limitation to the present disclosure.

[0019] After the user uses an existing massager for a long time, it is easy to wear the skin, resulting in a less comfortable massage experience.

[0020] Embodiments of the present disclosure provide a massage mechanism and a massager, to solve at least one of the technical problems described above.

[0021] Referring to FIG. 1 to FIG. 4, a massage mechanism **100** is provided in an embodiment of the present disclosure. The massage mechanism **100** includes a housing **10**, a driving motor **20**, two eccentric wheels **30**, two swing rods **40** symmetrically arranged, and two massage heads **50** symmetrically arranged. The housing **10** is provided with two elongated slots **11**. The driving motor **20** is fixedly disposed at the housing **10**. The two eccentric wheels **30** are disposed at the housing **10**. The two eccentric wheels **30** are in transmission connection with the driving motor **20** to rotate under the drive of the driving motor **20**. Each eccentric wheel **30** is provided with an eccentric connection portion **31**. The eccentric connection portion **31** is spaced apart from a central axis of the eccentric wheel **30**. Each of the two swing rods **40** symmetrically arranged has a first end **41** and a second end **42** opposite to the first end **41** in the length direction of the swing rod. The first end **41** is hinged to the eccentric connection portion **31** to rotate 360° around the central axis of the eccentric wheel **30** along with the eccentric connection portion **31**. Second ends **42** of the two swing rods **40** are respectively received in the two elongated slots **11**, to allow each second end **42** to linearly reciprocate and limit motion of the second end **42** in a direction perpendicular to the length direction of the swing rod **40**. The two massage heads **50** extend out of the housing **10** to massage a target massage area. The two massage heads **50** are fixedly connected to the second ends **42** of the two swing rods **40** respectively. In a process of 360° rotation of the first end **41** of each of the two swing rods **40** around the central axis of the eccentric wheel **30** under the drive of the eccentric wheel **30**, the two massage heads **50** are close to or away from each other, and each are configured to perform a yaw motion around a rotation axis parallel to the central axis of the eccentric wheel **30** in a preset angle range.

[0022] In the massage mechanism **100** of embodiments of the present disclosure, the two eccentric wheels **30** and the two massage heads **50** are connected through the two swing rods **40**, respectively. The massage head **50** is fixedly connected to the second end **42** of the swing rod **40**. The second end **42** linearly reciprocates in the elongated slot **11**. The massage head **50**, along with the second end **42**, performs a small amplitude of the yaw motion around the rotation axis parallel to the central axis of the eccentric wheel **30** in the preset angle range, and does not rotate 360° along with the eccentric wheel **30**. Therefore, after the two massage heads **50** contact with the skin of the user, the two massage heads **50** only move on a fixed plane parallel to the plane where the elongated slots **11** are defined, and the movement amplitude of the two massage heads **50** at the target massage area is relatively small. Thus, after the user is massaged for a long time, it is not easy to wear the skin of the user, and the massage comfort is improved.

[0023] Specifically, the housing **10** may serve as a mounting carrier for the driving motor **20**, the eccentric wheel **30**, and other elements, and protect the driving motor **20**, the eccentric wheel **30**, and other elements. The housing **10** may be made of a plastic material, so that the massage mechanism **100** is relatively lightweight as a whole. The housing **10** is provided with the two elongated slots **11**, and the two elongated slots **11** are symmetrical about a central axis (as shown

by a dotted line O.sub.1 in FIG. 1) of the housing **10** extending in the width direction of the housing **10**. A length extension direction of each of the two elongated slots **11** is parallel to a length direction of the housing **10** (as shown by X direction in FIG. 3). An extension direction of the width of each of the two elongated slots **11** is parallel to a width direction of the housing **10** (as shown by Y direction in FIG. 3). An extension direction of the depth of each of the two elongated slots **11** is parallel to a height direction of the housing **10** (as shown by Z direction in FIG. 3). [0024] The driving motor **20** is fixedly disposed at the housing **10**, and specifically, may be fixedly mounted inside the housing **10**. A power output direction of the driving motor **20** (that is, a direction of a motor output shaft) may be parallel to the width direction of the housing **10**. The number of driving motors **20** may be one or more. When there is one driving motor **20**, an internal space of the housing **10** that is occupied by the driving motor can be reduced and the cost can be saved.

[0025] The two eccentric wheels **30** are disposed at the housing **10**, and specifically, may be partially located inside the housing **10** and partially located outside the housing **10**. The two eccentric wheels **30** are symmetrical about the central axis of the housing **10** extending in the width direction of the housing **10**. A direction of a central axis (as shown by a dotted line O.sub.2 in FIG. 4) of the eccentric wheel **30** may be parallel to the height direction of the housing **10**. The two eccentric wheels **30** are in transmission connection with the driving motor **20**. The driving motor **20** may directly drive the two eccentric wheels **30** to rotate, or indirectly drive the two eccentric wheels **30** to rotate. Referring to FIG. 2, in an example, when the driving motor **20** indirectly drives the two eccentric wheels **30** to rotate, the driving motor **20** transmits power to some intermediate gear members first, and then transmits the power to the two eccentric wheels **30**. When there is one driving motor **20**, one driving motor **20** is located at a middle position of the two eccentric wheels **30**, so that one driving motor **20** can be utilized to drive the two eccentric wheels **30** to rotate synchronously, thereby driving the two swing rods **40** to move, and realizing massage by the two massage heads **50**. Referring to FIG. 4, the eccentric connection portion **31** is further disposed on each eccentric wheel **30**. The eccentric connection portion **31** is spaced apart from the central axis of the eccentric wheel **30**. The eccentric connection portion **31** is located at one side of the eccentric wheel **30** facing the housing **10** to be connected to the corresponding swing rod **40**.

[0026] The two swing rods **40** are located at one side of the housing **10** facing outward and are symmetrical about the central axis of the housing **10** extending in the width direction of the housing **10**. Each swing rod **40** has the first end **41** and the second end **42** opposite to the first end **41** in the length direction of the swing rod. The first end **41** defines a rotating-axis hole, and the rotating-axis hole is sleeved on the eccentric connection portion **31**, so that the first end **41** can be hinged to the eccentric connection portion **31**. When the driving motor **20** drives the eccentric wheel **30** to rotate, the first end **41** rotates 360°, along with the eccentric connection portion **31**, about the central axis of the eccentric wheel **30**. The width of the second end **42** is greater than the width of the first end **41** (when each of the first end **41** and the second end **42** is substantially circular, the width herein is an outer diameter). The second end **42** is received in the elongated slot **11**, and the width of the elongated slot **11** is in fit with the width of the second end **42**. For example, the width of the elongated slot **11** is equal to the width of the second end **42**, or the width of the elongated slot **11** is slightly greater than the width of the second end **42**. Since the elongated slot **11** is in a long strip shape, it is possible to limit the motion of the second end **42** in the direction perpendicular to the length direction of the swing rod **40**, while allowing the second end **42** to linearly reciprocate in the length direction of the elongated slot **11**.

[0027] The two massage heads **50** extends out of the housing **10** and configured to contact the target massage area, for example, apply an active force to massage the target massage area. The target massage area may be the neck and other parts of the user. When massaging, the two massage heads **50** may be respectively located at two sides of the target massage area. The two massage heads **50** are symmetrical about the central axis of the housing **10** extending in the width direction

of the housing. It may be noted that, in embodiments of the present disclosure, “two” may be two or two groups. When there are two massage heads **50**, the two massage heads **50** are symmetrical about the central axis of the housing **10** extending in the width direction of the housing. When there are two groups of massage heads **50**, the two groups of massage heads **50** are symmetrical about the central axis of the housing **10** extending in the width direction of the housing. Each group of massage heads **50** may include one or more massage heads **50**. For example, each group of massage heads **50** may include two massage heads **50**. Each massage head **50** is substantially spherical to improve the massage comfort. The two massage heads **50** are fixedly connected to the second ends **42** of the two swing rods **40**, respectively. The fixed connection herein means that after the massage head **50** is mounted to the second end **42** of the swing rod **40**, the massage head **50** and the swing rod **40** do not move relative to each other, for example, do not rotate or move relative to each other. However, the massage head **50** and the swing rod **40** may be detachable or non-detachable relative to each other, which is not limited herein. Alternatively, the massage head **50** may be directly connected to the swing rod **40**, or indirectly connected to the swing rod **40** through an extension portion **441** in the following. In a process of 360° rotation of the first end **41** of each of the two swing rods **40** around the central axis of the eccentric wheel **30** under the drive of the eccentric wheel **30**, the two massage heads **50** are close to or away from each other in the length direction of the housing **10**, and each are configured to perform the yaw motion around the rotation axis parallel to the central axis of the eccentric wheel **30** in the preset angle range.

[0028] The rotation axis parallel to the central axis of the eccentric wheel **30** may be a central axis (as shown by a dashed line O.sub.3 in FIG. 5) of the second end **42**. The yaw motion includes rotation around the fore-mentioned rotation axis towards in a direction close to the target massage area and rotation around the fore-mentioned rotation axis towards a direction away from the target massage area. The preset angle range may be set according to actual situations, as long as the two massage heads **50** can perform a small amplitude of the yaw motion around the rotation axis parallel to the central axis of the eccentric wheel **30**, which is not limited herein. For example, the preset angle range may be set within 45°, and the two massage heads **50** can rotate around the rotation axis in the direction close to the target massage area in the angle range of 45°, and rotate around the rotation axis in the direction away from the target massage area in the angle range of 45°.

[0029] The overall operation process of the massage mechanism **100** in embodiments of the present disclosure is as follows. The driving motor **20** drives the two eccentric wheels **30** to rotate, and the corresponding eccentric connection portion **31** on each eccentric wheel **30** rotates 360° around the central axis of the eccentric wheel **30**. Since the first end **41** of the swing rod **40** is hinged to the eccentric connection portion **31**, the first end **41** of the swing rod **40** rotates 360°, along with the corresponding eccentric connection portion **31**, around the central axis of the eccentric wheel **30**. When the first ends **41** of the two swing rods **40** rotate, the second ends **42** of the two swing rods **40** are driven to linearly reciprocate, respectively. The second ends **42** of the two swing rods **40** are respectively received in the two elongated slots **11** to limit the second ends **42**, that is, to limit the motion of each second end **42** in the direction perpendicular to the length direction of the corresponding swing rod **40** while allowing each second end **42** to linearly reciprocate. When the second ends **42** of the two swing rods **40** linearly reciprocate, the two massage heads **50** fixedly connected to the second ends **42** of the two swing rods **40** are driven to linearly reciprocate, so that the two massage heads **50** are close to or away from each other. Meanwhile, the two massage heads **50** each perform a yaw motion around the rotation axis parallel to the central axis of the eccentric wheel **30** in the preset angle range, so as to massage the target massage area.

[0030] Referring to FIG. 1 to FIG. 3, and FIG. 5, in some embodiments, the housing **10** has a housing surface **12**. The driving motor **20** is disposed at one side of the housing surface **12** facing the interior of the housing **10**. The two swing rods **40** are disposed at one side of the housing surface **12** facing the exterior of the housing **10**. Each swing rod **40** includes a first connection arm

43 and a second connection arm **44** connected to the first connection arm **43**. The first connection arm **43** is hinged to the eccentric connection portion **31**. The first connection arm **43** extends from the first end **41** to the second end **42** and is close to the housing surface **12**. The second connection arm **44** extends from the second end **42** in a direction away from the housing surface **12** to be fixedly connected to the corresponding massage head **50**.

[0031] Specifically, the swing rod **40** is substantially L-shaped. The first connection arm **43** extends from the first end **41** to the second end **42** and is close to the housing surface **12**. The second connection arm **44** extends from the second end **42** in the direction away from the housing surface **12**, and the length of the L-shaped swing rod **40** extending towards the target massage area is made to be as short as possible. Thus, during massage, the length of the arm of force of the counterforce applied to the swing rod **40** by the target massage area can be shortened, so that the mechanical strength of the swing rod **40** can be improved.

[0032] Referring to FIG. 3 and FIG. 5, in some embodiments, a reinforcing structure **45** is disposed at a connection of the first connection arm **43** and the second connection arm **44**. The reinforcing structure **45** includes a first reinforcing structure **451** disposed in a length direction of the first connection arm **43** and connected to the second connection arm **44**, and/or a second reinforcing structure **452** disposed in a length direction of the second connection arm **44** and connected to the first connection arm **43**.

[0033] Specifically, the reinforcing structure **45** may only include the first reinforcing structure **451**. Alternatively, the reinforcing structure **45** may only include the second reinforcing structure **452**. Alternatively, the reinforcing structure **45** includes both the first reinforcing structure **451** and the second reinforcing structure **452**. The reinforcing structure **45** can increase the structural strength of the swing rod **40**. Thus, during massage, the possibility that the swing rod **40** is cracked due to the counterforce by the target massage area can be reduced.

[0034] Referring to FIG. 1 and FIG. 6, in some embodiments, two through holes **121** are defined on the housing surface **12**. The interior of the housing **10** is in communication with the exterior of the housing **10** through the two through holes **121**. The two eccentric wheels **30** are respectively disposed in the two through holes **121**. Each eccentric wheel **30** has a cam surface **32** facing the exterior of the housing **10**. The eccentric connection portion **31** extends from the cam surface **32** and is at least partially located outside the through hole **121** to be hinged to the first end **41** of the swing rod **40**.

[0035] Specifically, there may be a height difference between the cam surface **32** and the housing surface **12**. The height difference may be in a range of ± 2 mm. For example, the height difference between the cam surface **32** and the housing surface **12** may be -2 mm, -1 mm, 0 mm, 1 mm, 2 mm, or any other value in the range of ± 2 mm, which is not limited herein. The eccentric connection portion **31** extends from the cam surface **32** and is hinged to the first end **41** of the swing rod **40**. Thus, the length of part of the eccentric connection portion **31** that is connected to the first end **41** of the swing rod **40** in the axial direction (as shown by a direction of Z axis in FIG. 3) can be shortened, to improve the mechanical strength. In addition, the mechanical overhead during the movement of the swing rod **40** can also be reduced.

[0036] Referring to FIG. 3 and FIG. 5, in some embodiments, an angle between a length extension direction of the first connection arm **43** and a length extension direction of the second connection arm **44** ranges from 80° to 100° .

[0037] Specifically, the swing rod **40** is substantially L-shaped. The first connection arm **43** is close to the housing surface **12**. Changing the angle between the length extension direction of the first connection arm **43** and the length extension direction of the second connection arm **44** is equivalent to changing an inclination angle of the second connection arm **44** relative to the first connection arm **43**. If the angle range is set to be too large or too small, the inclination angle of the second connection arm **44** may be too large or too small. However, if the inclination angle of the second connection arm **44** is too large or too small, it is necessary to lengthen the length of the second

connection arm **44** to contact the target massage area, thus resulting in a decrease in the mechanical strength of the swing rod **40**.

[0038] In embodiments of the present disclosure, the angle range of the L-shaped swing rod **40**, that is, the range of the angle between the length extension direction of the first connection arm **43** and the length extension direction of the second connection arm **44**, is set to be of 80° to 100°, so that the second connection arm **44** of the swing rod **40** facing the target massage area only needs to have a short length to contact the target massage area. The specific angle may be set according to actual situations. For example, the angle between the length extension direction of the first connection arm **43** and the length extension direction of the second connection arm **44** may be set to be 80°, 85°, 90°, 95°, 100°, or any other value between 80° and 100°, which is not limited herein.

[0039] Referring to FIG. 1, in some embodiments, at least one rib **111** is disposed in each elongated slot **11** and extends in a linear motion direction of the second end **42**. Each rib **111** has a rib top-surface **1111** facing the exterior of the housing **10**. The rib top-surface **1111** is configured to be in sliding fit with the second end **42** when the second end **42** linearly reciprocate along the corresponding elongated slot **11**. A plane that is flush with the rib top-surface **1111** in each elongated slot **11** is recessed towards the interior of the housing **10** to define at least two oil storage grooves **112**. The at least two oil storage grooves **112** and the at least one rib **111** are alternately arranged in a width direction of the elongated slot **11**.

[0040] Specifically, when the user uses the massager **200** to massage, the second end **42** of the swing rod **40** may be subjected to an axial pressing force (that is, counterforce) by the target massage area. The rib **111** is disposed in the elongated slot **11**, so that the second end **42** of the swing rod **40** can be supported when the swing rod **40** is subjected to the axial pressing force.

[0041] In addition, the plane that is flush with the rib top-surface **1111** in each elongated slot **11** is recessed towards the interior of the housing **10** to define the oil storage groove **112**. The oil storage groove **112** can be used for storing lubricating oil. When the second end **42** linearly reciprocates in the elongated slot **11**, the lubricating oil stored in the oil storage groove **112** can reduce the sliding friction during the motion, so that the obstruction or even stop of the motion of the swing rod **40** due to excessive sliding friction can be avoided.

[0042] Referring to FIG. 1, in some embodiments, the rib top-surface **1111** is recessed towards the interior of the housing **10** to define multiple oil storage holes **113**. The multiple oil storage holes **113** are defined at intervals in the linear motion direction of the second end **42**.

[0043] Specifically, similar to the oil storage groove **112**, the oil storage hole **113** can also be used for storing lubricating oil. When the second end **42** of the swing rod **40** linearly reciprocates along the elongated slot **11** and the rib top-surface **1111** is in sliding fit with the second end **42**, the lubricating oil stored in the oil storage hole **113** can further reduce sliding friction during the motion, so that the obstruction or even stop of the motion of the swing rod **40** due to excessive sliding friction can be further avoided.

[0044] Referring to FIG. 1, in some embodiments, two spaced ribs **111** are disposed in each elongated slot **11**. The two ribs **111** are symmetrical in the width direction of the elongated slot **11**.

[0045] Specifically, the second end **42** of the swing rod **40** has a certain width. Compared with only one rib **111**, the two ribs **111** can support the second end **42** more stably. Meanwhile, compared with more ribs **111**, the two ribs **111** are sufficient to stably support the second end **42**, so that the space at the bottom of the elongated slot **11** can be fully utilized to define the oil storage groove **112**.

[0046] Referring to FIG. 5 and FIG. 6, in some embodiments, the massage mechanism **100** further includes a cover plate **60**. The housing surface **12** is recessed towards the interior of the housing **10** to define a recess **122**. The two swing rods **40** are at least partially received in the recess **122** and covered with the cover plate **60**. The cover plate **60** defines two elongated holes **61**. The two elongated holes **61** respectively allow the second ends **42** of the two swing rods **40** to linearly

reciprocate along the two elongated slots **11**.

[0047] Specifically, the two swing rods **40** may be partially disposed in the recess **122**, or may be entirely disposed in the recess **122**. The two swing rods **40** are covered with the cover plate **60**. The two elongated holes **61** are defined on the cover plate **60** to allow the second ends **42** of the two swing rods **40** to respectively linearly reciprocate along the two elongated slots **11**. Thus, with the arrangement of the cover plate **60**, not only can pinching hand be prevented, but also the normal motion of the swing rod **40** cannot be affected.

[0048] Referring to FIG. 7, in some embodiments, the width of the elongated slot **11** is greater than or equal to the diameter of the second end **42**. The diameter of the second end **42** is greater than the width of the elongated hole **61**.

[0049] Specifically, the width of the elongated slot **11** is greater than or equal to the diameter of the second end **42**, to facilitate the second end **42** to linearly reciprocate in the elongated slot **11**. In practical applications, the swing rod **40** may be abnormally stressed. For example, if the user forcefully pulls the massage head **50** outwards, the swing rod **40** is easy to be separated from the cover plate **60** when being abnormally stressed, resulting in a malfunction of the massage mechanism **100** and affecting use. Therefore, the diameter of the second end **42** is designed to be greater than the width of the elongated hole **61**, so that the second end **42** may be clamped in the elongated hole **61**, thereby effectively preventing the swing rod **40** from separating from the cover plate **60** when being abnormally stressed.

[0050] Referring to FIG. 7 and FIG. 8, in some embodiments, the massage mechanism **100** further includes a flexible housing **70**. The flexible housing **70** covers the cover plate **60** at one side of the cover plate **60** opposite to the two swing rods **40**. The flexible housing **70** defines two opening holes **71** for allowing the two massage heads **50** to extend out the flexible housing **70** respectively. Positions of the two opening holes **71** respectively correspond to middle positions of the two elongated holes **61**. An opening size of each of the two opening holes **71** is less than an opening size of each of the two elongated holes **61**.

[0051] Specifically, the flexible housing **70** is made of a flexible material, such as, silica gel. The flexible housing **70** covers the cover plate **60** at one side of the cover plate **60** opposite to the two swing rods **40**. The two opening hole **71** are defined on the flexible housing **70**, so that the two massage heads **50** can extend out. The opening size of each of the two opening holes **71** is less than the opening size of each of the two elongated holes **61**. Thus, the two elongated holes **61** on the cover plate **60** can be blocked to prevent pinching hand.

[0052] Since the opening size of each of the two opening holes **71** is less than the opening size of each of the two elongated holes **61**, the swing rod **40** may pull the flexible housing **70** during the motion of the swing rod **40**. Therefore, the two opening holes **71** can be respectively defined at positions of the flexible housing **70** corresponding to the middle positions of the two elongated holes **61**. In this way, excessive pulling of the flexible housing **70** can be avoided.

[0053] Referring to FIG. 1 to FIG. 3, in some embodiments, the massage mechanism **100** further includes two massage housings **80**. The two massage housings **80** respectively cover two massage heads **50**. An outer surface of each of the two massage housings **80** forms a diamond-like structure that is symmetrical about a central axis (as shown by a dotted line O.sub.4 in FIG. 3) of each of the two massage housings **80**.

[0054] Specifically, the outer surface of the massage housing **80** is designed to have a diamond-like structure, so that the massage housing **80** has a better touch feeling when being in contact with the skin of the user, and the massage comfort is improved.

[0055] Referring to FIG. 1 and FIG. 2, in some embodiments, the massage mechanism **100** further includes two massage housings **80**. The two massage housings **80** respectively cover two massage heads **50**. Each of the two massage housings **80** includes a first housing part **81** close to the target massage area and a second housing part **82** away from the target massage area. The first housing part **81** and the second housing part **82** are symmetrical about a central axis of each of the two

message housings **80**. The first housing part **81** is a flexible message housing. The second housing part **82** is a rigid message housing.

[0056] Specifically, the flexible message housing is made of a flexible material, such as, silica gel. The first housing part **81** close to the target message area is designed as the flexible message housing, so that the message housing **80** has a better touch feeling when being in contact with the skin of the user, and the message comfort is improved. The second housing part **82** away from the target message area is designed as the rigid message housing, so that the structural strength of the message housing **80** can be improved.

[0057] Referring to FIG. 1, FIG. 2, and FIG. 7, in some embodiments, the two message heads **50** are two groups of message heads **50**. Each of the two groups of message heads **50** includes a first message head **51** and a second message head **52**. The second connection arm **44** is provided with two extension portions **441** at one end of the second connection arm **44** away from the housing surface **12**. The two extension portions **441** respectively extend from the second connection arm **44** to opposite sides of the second connection arm **44** in the width direction of the housing **10**, and are gradually away from the housing surface **12**. The first message head **51** and the second message head **52** are respectively fixed to the two extension portions **441**. When the two groups of message heads **50** each perform the yaw motion around the rotation axis parallel to the central axis of the eccentric wheel **30** in the preset angle region, two corresponding first message heads **51** in the two groups of message heads **50** are close to the target message area and two corresponding second message heads **52** in the two groups of message heads **50** are away from the target message area, or the two corresponding first message heads **51** in the two groups of message heads **50** are away from the target message area and the two corresponding second message heads **52** in the two groups of message heads **50** are close to the target message area.

[0058] Specifically, the two groups of message heads **50** each perform the yaw motion around the rotation axis parallel to the central axis of the eccentric wheel **30** in the preset angle range. Two corresponding first message heads **51** and two corresponding second message heads **52** in the two groups of message heads **50** alternately approach and move away from the target message area, and respectively massage different regions of the target message area. In this way, the two corresponding first message heads **51** and the two corresponding second message heads **52** in the two groups of message heads **50** alternately massage the target message area, so that after the user is massaged for a long time, it is not easy to wear the skin of the user, and the message comfort is improved.

[0059] It can be understood that, in the process of the yaw motion of the two groups of message heads **50**, at least part of the process is fore-mentioned “the two corresponding first message heads **51** in the two groups of message heads **50** are close to the target message area and the two corresponding second message heads **52** in the two groups of message heads **50** are away from the target message area, or the two corresponding first message heads **51** in the two groups of message heads **50** are away from the target message area and the two corresponding second message heads **52** in the two groups of message heads **50** are close to the target message area”. In addition, the process of the yaw motion of the two groups of message heads **50** may also include “the two corresponding first message heads **51** in the two groups of message heads **50** are close to the target message area and the two corresponding second message heads **52** in the two groups of message heads **50** are also close to the target message area”, “the two corresponding first message heads **51** in the two groups of message heads **50** are away from the target message area and the two corresponding second message heads **52** in the two groups of message heads **50** are also away from the target message area”, and other processes, which is not limited herein.

[0060] When the two groups of message heads **50** each perform the yaw motion around the rotation axis parallel to the central axis of the eccentric wheel **30** in the preset angle range, the two groups of message heads **50**, as a whole, linearly reciprocate in the two elongated slots **11** following the second ends **42** of the two swing rods **40**, respectively. Therefore, when the two groups of message

heads **50** are close to or away from each other as a whole, the two corresponding first massage heads **51** in the two groups of massage head **50** and the two corresponding second massage heads **52** in the two groups of massage heads **50** are alternatively close to and away from the target massage area.

[0061] Referring to FIG. **9**, in some embodiments, the length from the eccentric connection portion **31** to the second end **42** ranges from 30 mm to 50 mm. An eccentric radius of the eccentric wheel **30** ranges from 8 mm to 15 mm.

[0062] Specifically, the length from the eccentric connection portion **31** to the second end **42** is represented by L, which refers to the length from a central point of the eccentric connection portion **31** to a central point of the second end **42**, and ranges from 30 mm to 50 mm. For example, the length L from the eccentric connection portion **31** to the second end **42** is 30 mm, 35 mm, 40 mm, 45 mm, 50 mm, or any other value between 30 mm and 50 mm, which is not limited herein. The eccentric radius of the eccentric wheels **30** is represented by R and ranges from 8 mm to 15 mm. For example, the eccentric radius R of the eccentric wheels **30** is 8 mm, 9 mm, 10 mm, 11 mm, 12 mm, 13 mm, 14 mm, 15 mm, or any other value between 8 mm and 15 mm, which is not limited herein. When the length from the eccentric connection portion **31** to the second end **42** is set in a range of 30 mm to 50 mm, and the eccentric radius R of the eccentric wheels **30** is set in a range of 8 mm to 15 mm, an angle at which the massage heads **50** alternately perform yaw motion can be controlled in a proper range, thereby improving the massage comfort.

[0063] Referring to FIG. **10**, a massager **200** is further provided in embodiments of the present disclosure. The massager **200** includes the massage mechanism **100** of any one of the foregoing embodiments. The massager **200** may be, such as, a neck massager for the user to massage the neck.

[0064] In conclusion, in the massage mechanism **100** and the massager **200** of embodiments of the present disclosure, the two eccentric wheels **30** and the two massage heads **50** are connected through the two swing rods **40**, respectively. The massage head **50** is fixedly connected to the second end **42** of the swing rod **40**. The second end **42** linearly reciprocates in the elongated slot **11**. The massage head **50**, along with the second end **42**, performs a small amplitude of the yaw motion around the rotation axis parallel to the central axis of the eccentric wheel **30** in the preset angle range, and does not rotate 360° along with the eccentric wheel **30**. Therefore, after the two massage heads **50** contact with the skin of the user, the two massage heads **50** only move on the fixed plane parallel to the plane where the elongated slots **11** are defined, and the movement amplitude of the two massage heads **50** at the target massage area is relatively small. Thus, after the user is massaged for a long time, it is not easy to wear the skin of the user, and the massage comfort is improved.

[0065] In the description of the present disclosure, it is necessary to understand that orientation or positional relations indicated by terms such as “center”, “longitudinal”, “transverse”, “length”, “width”, “thickness”, “upper”, “lower”, “front”, “back”, “left”, “right”, “vertical”, “horizontal”, “top”, “bottom”, “inside”, “outside”, “clockwise”, “counter-clockwise” are orientation or positional relations based on the accompanying drawings, are only for facilitating description of the present disclosure and simplifying the description, rather than indicating or implying that the referred devices or elements must be in a particular orientation or constructed or operated in the particular orientation, and therefore they may not be construed as limiting the present disclosure. In addition, terms “first”, “second”, and the like are only used for description and cannot be understood as explicitly or implicitly indicating relative importance or implicitly indicating the number of technical features referred to herein. Therefore, features restricted by terms “first”, “second”, and the like can explicitly or implicitly include at least one of the features. In the description of the present disclosure, unless specified otherwise, “multiple” refers to “at least two”.

[0066] It may be noted that, unless specified or limited otherwise, in the description of the present disclosure, terms “mounting”, “coupling”, “connecting”, and the like referred to herein may be

understood in broader sense. For example, coupling may be a fixed coupling, a detachable coupling, or an integrated coupling, may be a mechanical coupling, an electrical coupling, and may be a direct coupling, an indirect coupling through a medium, or a communication coupling between two components or an interaction coupling between two components. For those of ordinary skill in the art, the above terms in the present disclosure can be understood according to specific situations. [0067] In the present disclosure, unless specified or limited otherwise, a structure in which a first feature is “on” or “below” a second feature may include an embodiment in which the first feature is in direct contact with the second feature, and may also include an embodiment in which the first feature and the second feature are not in direct contact with each other, but are contacted via an additional feature formed therebetween. In addition, a first feature “on”, “above”, or “on top of” a second feature may include an embodiment in which the first feature is right or obliquely “on”, “above”, or “on top of” the second feature, or just means that the first feature is at a height higher than that of the second feature; while a first feature “below”, “under”, or “on bottom of” a second feature may include an embodiment in which the first feature is right or obliquely “below”, “under”, or “on bottom of” the second feature, or just means that the first feature is at a height lower than that of the second feature.

[0068] The above disclosure provides many different embodiments or examples for implementing different structures of the present disclosure. In order to simplify the present disclosure, certain elements and settings are described above. However, these elements and settings are only examples and are not intended to limit the present disclosure. In addition, reference numerals and/or letters may be repeated in different examples in the present disclosure. This repeating is for the purpose of simplification and clarity and does not refer to relations between various embodiments and/or settings. In addition, examples of particular processes and materials are provided herein, but those of ordinary skill in the art can recognize applications of other processes and/or use of other materials.

[0069] Reference throughout this specification to “some embodiments”, “an embodiment”, “an example”, “a specific example”, or “some examples”, means that a particular feature, structure, material, or characteristic described in connection with the embodiment or example is included in at least one embodiment or example of the present disclosure. In this specification, exemplary descriptions of aforesaid terms are not necessarily referring to the same embodiment or example. In addition, the particular features, structures, materials, or characteristics may be combined in any suitable manner in one or more embodiments or examples.

[0070] Although embodiments of the present disclosure have been shown and described above, it would be appreciated by those of ordinary skill in the art that changes, modifications, replacements, and modifications can be made to these embodiments without departing from the principles and spirit of the present disclosure. The scope of the present disclosure is defined by the claims and equivalents thereof.

Claims

1. A massage mechanism, comprising: a housing, wherein the housing is provided with two elongated slots; a driving motor fixedly disposed at the housing; two eccentric wheels disposed at the housing, wherein the two eccentric wheels are in transmission connection with the driving motor to rotate under the drive of the driving motor, each of the two eccentric wheels is provided with an eccentric connection portion, and the eccentric connection portion is spaced apart from a central axis of each of the two eccentric wheels; two swing rods symmetrically arranged, wherein each of the two swing rods has a first end and a second end opposite to the first end in a length direction of each of the two swing rods, the first end is hinged to the eccentric connection portion to rotate 360° around the central axis of each of the two eccentric wheels along with the eccentric connection portion, and second ends of the two swing rods are respectively received in the two

elongated slots to allow each of the second ends to linearly reciprocate and limit motion of each of the second ends in a direction perpendicular to the length direction of each of the two swing rods; and two massage heads extending out of the housing and configured to massage a target massage area, wherein the two massage heads are fixedly connected to the second ends of the two swing rods respectively, and in a process of 360° rotation of the first end of each of the two swing rods around the central axis of each of the two eccentric wheels under the drive of each of two eccentric wheels, the two massage heads are close to or away from each other, and each are configured to perform a yaw motion around a rotation axis parallel to the central axis of each of the two eccentric wheels in a preset angle range.

2. The massage mechanism of claim 1, wherein the housing has a housing surface, the driving motor is disposed at one side of the housing surface facing an interior of the housing, and the two swing rods are disposed at one side of the housing surface facing an exterior of the housing; and each of the two swing rods comprises a first connection arm and a second connection arm connected to the first connection arm, the first connection arm is hinged to the eccentric connection portion, the first connection arm extends from the first end to the second end and is close to the housing surface, and the second connection arm extends from the second end in a direction away from the housing surface to be fixedly connected one of the two massage heads.

3. The massage mechanism of claim 2, wherein a reinforcing structure is disposed at a connection of the first connection arm and the second connection arm; and the reinforcing structure comprises a first reinforcing structure disposed in a length direction of the first connection arm and connected to the second connection arm; and/or a second reinforcing structure disposed in a length direction of the second connection arm and connected to the first connection arm.

4. The massage mechanism of claim 2, wherein two through holes are defined on the housing surface, the interior of the housing is in communication with the exterior of the housing through the two through holes, and the two eccentric wheels are respectively disposed in the two through holes; and each of the two eccentric wheels has a cam surface facing the exterior of the housing, and the eccentric connection portion extends from the cam surface and is at least partially located outside each of the two through holes to be hinged to the first end of each of the two swing rods.

5. The massage mechanism of claim 4, wherein there is a height difference between the cam surface and the housing surface, and the height difference is in a range of ± 2 mm.

6. The massage mechanism of claim 2, wherein an angle between a length extension direction of the first connection arm and a length extension direction of the second connection arm ranges from 80° to 100°.

7. The massage mechanism of claim 1, wherein at least one rib is disposed in each of the two elongated slots and extends in a linear motion direction of the second end, each of the at least one rib has a rib top-surface facing an exterior of the housing, and the rib top-surface is configured to be in sliding fit with the second end when the second end linearly reciprocates along each of the two elongated slots; and a plane that is flush with the rib top-surface in each of the two elongated slots is recessed towards an interior of the housing to define at least two oil storage grooves, and the at least two oil storage grooves and the at least one rib are alternately arranged in a width direction of each of the two elongated slots.

8. The massage mechanism of claim 7, wherein the rib top-surface is recessed towards the interior of the housing to define a plurality of oil storage holes, and the plurality of oil storage holes are defined at intervals in the linear motion direction of the second end.

9. The massage mechanism of claim 7, wherein two spaced ribs are disposed in each of the two elongated slots, and the two ribs are symmetrical in the width direction of each of the two elongated slots.

10. The massage mechanism of claim 1, further comprising a cover plate, wherein the housing surface is recessed towards an interior of the housing to define a recess, and the two swing rods are at least partially received in the recess and covered with the cover plate; and the cover plate defines

two elongated holes, and the two elongated holes respectively allow the second ends of the two swing rods to linearly reciprocate along the two elongated slots.

11. The massage mechanism of claim 10, wherein a width of each of the two elongated slots is greater than or equal to a diameter of the second end, and the diameter of the second end is greater than a width of each of the two elongated holes.

12. The massage mechanism of claim 10, further comprising a flexible housing, wherein the flexible housing covers the cover plate at one side of the cover plate opposite to the two swing rods; and the flexible housing defines two opening holes for allowing the two massage heads to extend out of the flexible housing respectively, positions of the two opening holes respectively correspond to middle positions of the two elongated holes, and an opening size of each of the two opening holes is less than an opening size of each of the two elongated holes.

13. The massage mechanism of claim 1, further comprising two massage housings, wherein the two massage housings respectively cover the two massage heads, and an outer surface of each of the two massage housings forms a diamond-like structure that is symmetrical about a central axis of each of the two massage housings.

14. The massage mechanism of claim 1, further comprising two massage housings, wherein the two massage housings respectively cover the two massage heads, each of the two massage housings comprises a first housing part close to the target massage area and a second housing part away from the target massage area, the first housing part and the second housing part are symmetrical about a central axis of each of the two massage housings, the first housing part is a flexible massage housing, and the second housing part is a rigid massage housing.

15. The massage mechanism of claim 2, wherein the two massage heads are two groups of massage heads, each of the two groups of massage heads comprises a first massage head and a second massage head, the second connection arm is provided with two extension portions at one end of the second connection arm away from the housing surface, the two extension portions respectively extend from the second connection arm to opposite sides of the second connection arm in a width direction of the housing, and are gradually away from the housing surface, and the first massage head and the second massage head are respectively fixed to the two extension portions; and when the two groups of massage heads each perform the yaw motion around the rotation axis parallel to the central axis of each of the two eccentric wheels in the preset angle range, two corresponding first massage heads in the two groups of massage heads are close to the target massage area and two corresponding second massage heads in the two groups of massage heads are away from the target massage area, or the two corresponding first massage heads in the two groups of massage heads are away from the target massage area and the two corresponding second massage heads in the two groups of massage heads are close to the target massage area.

16. The massage mechanism of claim 1, wherein a length from the eccentric connection portion to the second end ranges from 30 mm to 50 mm, and an eccentric radius of each of the two eccentric wheels ranges from 8 mm to 15 mm.

17. The massage mechanism of claim 1, wherein the rotation axis parallel to the central axis of each of the two eccentric wheels is a central axis of the second end.

18. A massager, comprising a massage mechanism, wherein the massage mechanism comprises: a housing, wherein the housing is provided with two elongated slots; a driving motor fixedly disposed at the housing; two eccentric wheels disposed at the housing, wherein the two eccentric wheels are in transmission connection with the driving motor to rotate under the drive of the driving motor, each of the two eccentric wheels is provided with an eccentric connection portion, and the eccentric connection portion is spaced apart from a rotation axis of each of the two eccentric wheels; two swing rods symmetrically arranged, wherein each of the two swing rods has a first end and a second end opposite to the first end in a length direction of each of the two swing rods, the first end is hinged to the eccentric connection portion to rotate 360° around the rotation axis of each of the two eccentric wheels along with the eccentric connection portion, and second

ends of the two swing rods are respectively received in the two elongated slots to allow each of the second ends to linearly reciprocate and limit motion of each of the second ends in a direction perpendicular to the length direction of each of the two swing rods; and two massage heads extending out of the housing and configured to massage a target massage area, wherein the two massage heads are fixedly connected to the second ends of the two swing rods respectively, and in a process of 360° rotation of the first end of each of the two swing rods around the rotation axis of each of the two eccentric wheels under the drive of each of two eccentric wheels, the two massage heads are close to or away from each other, and each are configured to perform a yaw motion around a rotation axis parallel to the rotation axis of each of the two eccentric wheels in a preset angle range.

19. The massager of claim 18, wherein the housing has a housing surface, the driving motor is disposed at one side of the housing surface facing an interior of the housing, and the two swing rods are disposed at one side of the housing surface facing an exterior of the housing; and each of the two swing rods comprises a first connection arm and a second connection arm connected to the first connection arm, the first connection arm is hinged to the eccentric connection portion, the first connection arm extends from the first end to the second end and is close to the housing surface, and the second connection arm extends from the second end in a direction away from the housing surface to be fixedly connected one of the two massage heads.

20. The massager of claim 18, wherein at least one rib is disposed in each of the two elongated slots and extends in a linear motion direction of the second end, each of the at least one rib has a rib top-surface facing an exterior of the housing, and the rib top-surface is configured to be in sliding fit with the second end when the second end linearly reciprocates along each of the two elongated slots; and a plane that is flush with the rib top-surface in each of the two elongated slots is recessed towards an interior of the housing to define at least two oil storage grooves, and the at least two oil storage grooves and the at least one rib are alternately arranged in a width direction of each of the two elongated slots.
