(57) **ABSTRACT**

A honeycomb-shaped catalyst for decomposition of perfluorinated compounds includes a body, a plurality of channels which penetrate the body from one surface thereof to a surface facing the one surface, and partition walls configured to define the channels. The honeycomb-shaped catalyst includes aluminum oxide and has a density of 300 g/L or more.

FIG. 1

FIG. 2

FIG. 3

#

[0021] According to some embodiments, a content of the aluminum oxide may be 40% by weight to 95% by weight based on a total weight of the catalyst.

[0022] According to some embodiments, the aluminum oxide may include at least one of alpha-alumina (α -Al₂O₃), beta-alumina (β -Al₂O₃), gamma-alumina (γ -Al₂O₃), delta-alumina (δ -Al₂O₃), theta-alumina (θ -Al₂O₃) and kappa-alumina (κ -Al₂O₃).

[0023] According to some embodiments, the catalyst may have a strength reduction rate of 45% or less, which is defined by Equation 3 below:

$$\text{Strength reduction rate (\%)} = 100 - \left[\left(1 - \left(S_E / S_I \right) \right) \times 100 \right] \quad [\text{Equation 3}]$$

[0024] In Equation 3, S_E may be a strength of the catalyst measured after passing a gas containing perfluorinated compounds for 300 hours, and S_I may be a strength of the catalyst measured without passing the gas containing perfluorinated compounds.

[0025] According to some embodiments, the catalyst may have a surface area reduction rate of 75% or less, which is defined by Equation 4 below:

$$\text{Surface area reduction rate (\%)} = 100 - \left[\left(1 - \left(A_E / A_I \right) \right) \times 100 \right] \quad [\text{Equation 4}]$$

[0026] In Equation 4, A_E may be a surface area of the catalyst measured after exposure to 950° C. for 4 hours, and A_I may be a surface area of the catalyst measured without exposure to heat.

[0027] According to another aspect of the present invention, there is provided a honeycomb-shaped catalyst assembly for decomposition of perfluorinated compounds, including a plurality of the above-described honeycomb-shaped catalysts for decomposition of perfluorinated compounds, which are stacked so that channels of the catalysts are connected with each other.

[0028] In addition, according to another aspect of the present invention, there is provided a method for removing perfluorinated compounds including: preparing the above-described honeycomb-shaped catalyst assembly for decomposition of perfluorinated compounds; and injecting a gas containing perfluorinated compounds into one surface of the honeycomb-shaped catalyst assembly for decomposition of perfluorinated compounds.

[0029] The honeycomb-shaped catalyst for decomposition of perfluorinated compounds according to the embodiments of the present invention includes aluminum oxide and has a density in a predetermined range or more. Accordingly, decomposition efficiency of perfluorinated compounds may be improved.

[0030] According to exemplary embodiments, the shape of the honeycomb-shaped catalyst for decomposition of perfluorinated compounds may be adjusted. Accordingly, lifespan characteristics of the catalyst for decomposition of perfluorinated compounds may be improved.

BRIEF DESCRIPTION OF THE DRAWINGS

[0031] The above and other objects, features and other advantages of the present invention will be more clearly

understood from the following detailed description taken in conjunction with the accompanying drawings, in which:

[0032] FIGS. 1 and 2 are a perspective view and a plan view schematically illustrating a honeycomb-shaped structure of a honeycomb-shaped catalyst for decomposition of perfluorinated compounds according to exemplary embodiments, respectively; and

[0033] FIG. 3 is a schematic cross-sectional view illustrating a reactor including a catalyst assembly according to exemplary embodiments.

DETAILED DESCRIPTION OF THE INVENTION

[0034] Hereinafter, embodiments of the present disclosure will be described in detail. However, these embodiments are merely an example, and the present disclosure is not limited to the specific embodiments described as the example.

[0035] The exemplary embodiments of the present invention provide a honeycomb-shaped catalyst (hereinafter, may be abbreviated as a “catalyst 100”) for decomposition of perfluorinated compounds including aluminum oxide and having a density in a predetermined range. In addition, a honeycomb-shaped catalyst assembly (hereinafter, may be abbreviated as a “catalyst assembly 200”) for decomposition of perfluorinated compounds including the honeycomb-shaped catalysts for decomposition of perfluorinated compounds is provided. In addition, a method for removing perfluorinated compounds using the catalyst is provided.

[0036] The term “contact area” as used herein may mean an area which is adjusted by the shape of the catalyst 100. For example, the contact area may be controlled by adjusting the number of channels per square inch (CPSI).

[0037] The term “surface area” as used herein may mean an area which is adjusted by pores included in the catalyst 100. For example, the surface area may be controlled by adjusting the size, volume, number, etc. of micropores included in the catalyst 100.

[0038] FIGS. 1 and 2 are a perspective view and a plan view schematically illustrating the structure of a honeycomb-shaped catalyst for decomposition of perfluorinated compounds according to exemplary embodiments, respectively. For example, FIG. 2 is a view illustrating an upper surface of the honeycomb-shaped catalyst for decomposition of perfluorinated compounds according to exemplary embodiments.

[0039] As used herein, the “height direction” may refer to a direction in which channels are formed. For example, the height direction may refer to a direction in which a gas containing perfluorinated compounds permeates. For example, the height direction may refer to a direction perpendicular to an x-axis direction and a y-axis direction in FIG. 2.

[0040] Referring to FIG. 1, the catalyst 100 may have a honeycomb shape including a plurality of channels 105. For example, the catalyst 100 may include a body 101, the plurality of channels 105 and partition walls 106 configured to define the channels 105.

[0041] In one embodiment, when perfluorinated compounds pass through the catalyst 100, an area in contact with the catalyst 100 may be increased through the plurality of channels 105, thereby increasing the decomposition efficiency of the perfluorinated compound.

[0042] According to exemplary embodiments, the plurality of channels 105 may penetrate the body from one surface

thereof to a surface facing the one surface. For example, the channels **105** may penetrate the body in a direction from a first surface **110** to a second surface **120** facing the first surface **110**.

[0043] According to exemplary embodiments, the channels **105** may be formed in the height direction. For example, when the first surface **110** and the second surface **120** may be connected through the channels **105**.

[0044] According to exemplary embodiments, cross-sectional shapes of the channel **105** may be constant throughout the sections in the height direction. For example, when lateral faces **150** are cut in the height direction of the catalyst **100** parallel to the first surface **110** and the second surface **120**, the cross-sectional shape of the channel **105** in a middle section may be the same as the cross-sectional shape of the channel on the first surface **110** and/or the cross-sectional shape of the channel on the second surface **120**. The gas containing perfluorinated compounds may pass through the plurality of channels **105** penetrating the catalyst **100**.

[0045] The cross-sectional shape of the channel **105** may not be limited to the cross-sectional shape shown in FIG. 1. For example, the cross-sectional shape of the channel **105** may correspond to a triangle, a rectangle, a square, a trapezoid, a rhombus, a hexagon, an oval, a circle and the like. In consideration of the contact area between the gas and the catalyst **100**, a flow rate, a density of the catalyst material included in the catalyst **100**, a strength of the catalyst **100**, and the like, the cross-sectional shape of the channel **105** may be formed as a triangle, a rectangle, or a hexagon.

[0046] According to exemplary embodiments, the plurality of channels **105** may be defined through the partition walls **106**.

[0047] In exemplary embodiments, the body **101** and the partition walls **106** may be made of the same material.

[0048] In some embodiments, the plurality of channels **105** may be spaced apart from each other at a predetermined interval. For example, the channels **105** may be spaced apart from each other in a direction perpendicular to the height direction by a distance corresponding to a thickness of the partition walls **106**.

[0049] In one embodiment, each of the plurality of channels **105** may have a rectangular cross-section, and distances (e.g., L2 in FIG. 2) between the plurality of channels **105** may be the same as each other.

[0050] In exemplary embodiments, the shape of the channel **105**, the number of the channels **105**, etc. may be adjusted to further improve the decomposition efficiency of perfluorinated compounds in the catalyst **100**.

[0051] In exemplary embodiments, a diameter of the channel **105** may be measured from a diameter of the channel located on the first surface **110** or the second surface **120**. For example, the diameter of the channel may be measured from the cross-section of the channel **105** identified on the first surface **110**.

[0052] According to exemplary embodiments, the catalyst **100** may have the number of channels per square inch (CPSI) of 20 or more. In some embodiments, the catalyst **100** may have the number of channels per square inch of 25 or more, 27 or more, 29 or more, or 30 or more.

[0053] In the present specification, the number of channels per square inch may be a value measured in a cross-section perpendicular to the height direction of the channels of the catalyst **100**.

[0054] According to exemplary embodiments, the number of channels per square inch of the catalyst **100** may be 250 or less. In some embodiments, the number of channels per square inch of the catalyst **100** may be 220 or less, 200 or less, 180 or less, 150 or less, or 130 or less.

[0055] For example, the number of channels per square inch of the catalyst **100** may be 20 to 250, 25 to 200, 27 to 180, 29 to 150, 30 to 150, or 30 to 130.

[0056] Within the above range, a unit area capable of being in contact with the perfluorinated compounds may be increased, and mobility of the gas may be maintained, thereby increasing catalytic activity per unit time.

[0057] In order to improve the lifespan, decomposition efficiency, etc. of the catalyst, the structure of the catalyst **100** may be adjusted. The structure of the catalyst **100** may be adjusted within a range enough to maintain the pores, density, strength, etc.

[0058] For example, longitudinal and lateral lengths of the catalyst **100** may be 10 mm to 30 mm, respectively. The longitudinal and lateral lengths may represent the length and width of the first section **110** or the second section **120**. For example, the catalyst **100** may have a height of 10 mm to 25 mm. The length is exemplary, and the size of the catalyst **100** is not limited thereto.

[0059] In exemplary embodiments, the catalyst **100** may include a catalyst material including a metal oxide having catalytic activity for decomposition of perfluorinated compounds.

[0060] According to exemplary embodiments, the catalyst **100** may include a catalyst material having catalytic activity.

[0061] In some embodiments, the catalyst material may include a metal oxide catalyst material. For example, the metal oxide catalyst material may include aluminum oxide, such as aluminum (I) oxide (Al_2O_3), aluminum (II) oxide (AlO_3), aluminum (II) oxide (Al_2O_3).

[0062] According to exemplary embodiments, the aluminum oxide may include one or more of alpha-alumina ($\alpha\text{-Al}_2\text{O}_3$), beta-alumina ($\beta\text{-Al}_2\text{O}_3$), gamma-alumina ($\gamma\text{-Al}_2\text{O}_3$), delta-alumina ($\delta\text{-Al}_2\text{O}_3$), theta-alumina ($\theta\text{-Al}_2\text{O}_3$) and kappa-alumina ($\kappa\text{-Al}_2\text{O}_3$). In one embodiment, the aluminum oxide may include one or more of alpha-alumina ($\alpha\text{-Al}_2\text{O}_3$) and gamma-alumina ($\gamma\text{-Al}_2\text{O}_3$).

[0063] In exemplary embodiments, the catalyst **100** may further include a ceramic material within a range that does not inhibit the catalytic activity of the catalyst material. For example, the catalyst **100** may further include a ceramic material such as silica, zeolite, cordierite, mullite, silica-alumina, titania, magnesia, $\text{Fe}_2\text{O}_3/\text{TiO}_2$, $\text{Fe}_2\text{O}_3/\text{Al}_2\text{O}_3$, MgO/TiO_2 , $\text{ZrO}_2/\text{Al}_2\text{O}_3$, ZrOx/TiO_2 , $\text{CeO}_2/\text{TiO}_2$, $\text{CeO}_2/\text{ZrO}_2$, $\text{V}_{205}/\text{TiO}_2$, etc.

[0064] According to exemplary embodiments, the catalyst **100** may include 40% by weight ("wt %") to 95 wt %, 50 wt % to 95 wt %, 50 wt % to 85 wt %, 50 wt % to 80 wt %, 50 wt % to 75 wt %, or 50 wt % to 70 wt % of the aluminum oxide catalyst material based on a total weight of the catalyst.

[0065] Within the above range, the decomposition efficiency of the perfluorinated compound may be maintained for a long period of time, and thermal stability may be improved.

[0066] In some embodiments, the catalyst **100** may further include elements such as oxygen (O), zirconium (Zr), zinc (Zn), tungsten (W), cerium (Ce), gallium (Ga), nickel (Ni), phosphorus (P), sulfur (S), and boron (B), etc. For example,

the catalyst **100** may further include a material formed of the above-described elements in addition to the aluminum oxide catalyst material.

[0067] In some embodiments, the catalyst **100** may have a monolithic structure in which components thereof are formed integrally with each other.

[0068] For example, an active ingredient such as aluminum oxide, a ceramic material, and the like may be mixed to form a slurry, and the slurry may be injected to form the catalyst **100** including the body **101**, the plurality of channels **105**, and the partition walls **106** which define the channels **105**. Accordingly, an amount of the active ingredient included in the catalyst **100** may be increased. In addition, the catalyst **100** having the above-described channel characteristics, pore characteristics, density, etc. may be reproducibly implemented.

[0069] The perfluorinated compound removal efficiency, lifespan characteristics, pressure loss, etc. of the catalyst **100** may be improved.

[0070] In exemplary embodiments, the catalyst **100** may have a density of 300 g/L or more. In some embodiments, the catalyst **100** may have a density of 350 g/L or more, 370 g/L or more, 380 g/L or more, 390 g/L or more, or 400 g/L or more.

[0071] According to exemplary embodiments, the catalyst **100** may have a density of 1,100 g/L or less.

[0072] In some embodiments, the catalyst **100** may have a density of 1,080 g/L or less, 1,050 g/L or less, 1,030 g/L or less, 1,020 g/L or less, 1,010 g/L or less, or 1,000 g/L or less. For example, the catalyst **100** may have a density of 300 g/L to 1,100 g/L, 350 g/L to 1,080 g/L, 370 g/L to 1,050 g/L, 380 g/L to 1,030 g/L, 390 g/L to 1,020 g/L, or 400 g/L to 1,000 g/L.

[0073] For example, if the density exceeds the above range, the diameter, volume, surface area, etc. of the channel may be decreased, and the decomposition efficiency of the perfluorinated compound decomposed by the unit mass of the catalyst may be reduced.

[0074] For example, if the density is less than the above range, a change in the size of the channel and/or pores may occur depending on the flow rate of the gas in a gas injection process. Thereby, the durability of the catalyst **100** may be decreased, and the amount of the catalyst material included in the catalyst **100** may be too small, thus to reduce the decomposition efficiency of the perfluorinated compound.

[0075] In exemplary embodiments, the catalyst **100** may include pores. For example, the volume of the pores included in the catalyst **100** may be controlled to further improve the decomposition efficiency of the perfluorinated compound.

[0076] The pores may refer to micropores included in the entire structure including the partition walls **106** of the catalyst **100**.

[0077] According to exemplary embodiments, the pores may have an average diameter of 50 Å to 300 Å, 52 Å to 280 Å, 54 Å to 260 Å, 55 Å to 250 Å, 58 Å to 200 Å, or 60 Å to 200 Å. In some embodiments, the pores may have an average diameter of 50 Å to 90 Å, 50 Å to 80 Å, or 50 Å to 75 Å.

[0078] For example, the average diameter of the pores may be measured by Brunauer-Emmett-Teller (BET) analysis. For example, the “average diameter” may represent the longest diameter of the pores at a point corresponding to 50% in a cumulative distribution where the pores are

arranged in order of size. For example, the average diameter of the pores may be a value measured when the catalyst **100** is exposed to 600° C. For example, when the catalyst **100** is exposed to a high temperature (e.g., 1,000° C.), the average diameter may be increased. Within the above diameter range, a differential pressure in the process of decomposing the perfluorinated compounds may be reduced, and thus damage to the catalyst **100** may be suppressed.

[0079] According to exemplary embodiments, a volume of the pores included per unit mass of the catalyst **100** may be 0.2 cm³/g or more.

[0080] In some embodiments, the volume of the pores included per unit mass of the catalyst **100** may be 0.25 cm³/g or more, 0.30 cm³/g or more, 0.32 cm³/g or more, 0.35 cm³/g or more, 0.38 cm³/g or more, or 0.40 cm³/g or more.

[0081] According to exemplary embodiments, the volume of the pores included per unit mass of the catalyst **100** may be 0.65 cm³/g or less, 0.62 cm³/g or less, 0.60 cm³/g or less, 0.58 cm³/g or less, or 0.56 cm³/g or less.

[0082] For example, the volume of the pores included per unit mass of the catalyst **100** may be 0.2 cm³/g to 0.65 cm³/g, 0.2 cm³/g to 0.60 cm³/g, 0.30 cm³/g to 0.60 cm³/g, 0.35 cm³/g to 0.60 cm³/g, or 0.40 cm³/g to 0.56 cm³/g.

[0083] Within the above volume range, the efficiency of the catalytic activity per unit time may be increased while securing the durability of the catalyst **100**.

[0084] For example, if the volume exceeds the above range, the strength of the catalyst **100** may be reduced, thereby causing a damage thereto in the decomposition process. For example, if the volume is less than the above range, the surface area per unit time of the catalyst and the gas containing perfluorinated compounds may be decreased, thereby decreasing the decomposition efficiency.

[0085] In exemplary embodiments, the volume of the pores and the average diameter of the pores included in the catalyst **100** may be measured by the BET method. For example, the volume of the pores and the average diameter of the pores may be values measured in an environment of 500° C.

[0086] The durability and lifespan of the catalyst may be improved by adjusting the density of the catalyst **100**, the size and number of the pores included in the catalyst **100**, etc., while maintaining the improved decomposition efficiency.

[0087] According to exemplary embodiments, the catalyst **100** may have a porosity of 10 to 100, which is defined by Equation 1 below.

$$\text{Porosity} = (PV/PD) \times 10^4 \quad [\text{Equation 1}]$$

[0088] In Equation 1, PV is a numerical value of the volume of the pores included per unit mass (cm³/g) of the catalyst **100**, and PD is a numerical value of the average diameter (Å) of the pores included in the catalyst **100**.

[0089] In exemplary embodiments, the porosity may be a dimensionless number.

[0090] According to exemplary embodiments, the porosity may be 15 to 90, 20 to 80, 25 to 75, or 30 to 70. Within the above range, the surface area of the catalyst **100** may be increased, thereby further improving the removal efficiency of perfluorinated compounds.

[0091] In exemplary embodiments, the catalyst **100** may come into contact with the perfluorinated compounds through contact surfaces including the first surface **110**, the second surface **120** and surfaces of the inner partition walls **106**.

[0092] For example, the contact area of the contact surfaces may be calculated as an area where the gas containing perfluorinated compounds and the catalyst **100** substantially come into contact with each other, except for an area of the lateral faces **150** of the catalyst **100**.

[0093] In exemplary embodiments, the surface area of the catalyst **100** may be controlled by adjusting the size of the pores, the volume of the pores, etc.

[0094] In some embodiments, the catalyst **100** may have a surface area per unit mass of 40 m²/g or more.

[0095] In some embodiments, the catalyst **100** may have a surface area per unit mass of 60 m²/g or more, 75 m²/g or more, 90 m²/g or more, 100 m²/g or more, 120 m²/g or more, 140 m²/g or more, or 150 m²/g or more.

[0096] Within the above surface area range, heat transfer may occur smoothly even at a relatively low temperature, thereby further enhancing the decomposition efficiency of the perfluorinated compounds.

[0097] According to exemplary embodiments, the catalyst **100** may have a catalyst material distribution index of 70 to 500, which is defined by Equation 2 below.

$$\text{Catalyst material distribution index} = \{D \times (L1/L2)\} \times 100 \quad [\text{Equation 2}]$$

[0098] In Equation 2, D is a numerical value of a density (kg/L) of the catalyst **100**, L1 is a numerical value of a length (mm) of the channel **105** of the catalyst **100**, and L2 is a numerical value of the shortest distance (mm) between two adjacent channels of the catalyst **100**.

[0099] In exemplary embodiments, the catalyst material distribution index may be a dimensionless number.

[0100] According to exemplary embodiments, the catalyst material distribution index may be 80 to 450, 85 to 400, 90 to 350, 95 to 300, or 100 to 250. When satisfying the above range, a decrease in the catalytic efficiency due to the reduction in the surface area may be prevented, while preventing a decrease in the strength and durability of the catalyst **100** and a decrease in the lifespan characteristics.

[0101] In Equation 2, the channel length L1 may represent a length (mm) in an x-direction of the channel **105** of the catalyst **100**, or otherwise, may represent a length (mm) in a y-direction of the channel **105**.

[0102] In Equation 2, the thickness L2 of the partition wall **106** is the shortest distance (mm) between two adjacent channels **105** of the catalyst **100**, and for example, may represent a length (mm) in the x direction between two adjacent channels **105**.

[0103] According to exemplary embodiments, the catalyst **100** may have a strength of 4 kgf/cm² or more.

[0104] The strength may be measured according to the method known in the art, and may represent a value measured from the catalyst **100** in the shape of a cube with each side having a length of 50 mm. In some embodiments, the catalyst **100** may have a strength of 6 kgf/cm² or more, 8 kgf/cm² or more, 10 kgf/cm² or more, 12 kgf/cm² or more, or 14 kgf/cm² or more.

[0105] According to exemplary embodiments, the catalyst **100** may have a strength of 60 kgf/cm² or less. In some embodiments, the catalyst **100** may have a strength of 59 kgf/cm² or less, 58 kgf/cm² or less, 57 kgf/cm² or less, 56 kgf/cm² or less, or 55 kgf/cm² or less.

[0106] For example, the catalyst **100** may have a strength of 4 kgf/cm² to 60 kgf/cm², 6 kgf/cm² to 59 kgf/cm², 8 kgf/cm² to 58 kgf/cm², 10 kgf/cm² to 56 kgf/cm², or 14 kgf/cm² to 55 kgf/cm².

[0107] Even if an external impact and an internal differential pressure are applied to the catalyst **100** within the above range, the shape thereof may be maintained. Accordingly, the durability and lifespan of the catalyst may be improved.

[0108] For example, a gas containing perfluorinated compounds may be injected into the first surface **110** of the catalyst **100**. A gas containing compounds generated by the decomposition of the perfluorinated compounds may be discharged through the second surface **120** of the catalyst **100**.

[0109] According to exemplary embodiments, a pressure loss value measured when the gas passes through the catalyst **100** in a flow rate of 90 CMM/m² may be 0.30 mmH₂O/m or less, 0.25 mmH₂O/m or less, 0.22 mmH₂O/m or less, or 0.20 mmH₂O/m or less.

[0110] Within the above range, energy consumption for gas flow of the catalyst **100** may be reduced. In addition, local reaction overload inside the catalyst **100** may be suppressed, thereby improving the decomposition efficiency.

[0111] For example, the differential pressure may appear in the process of permeating the gas containing perfluorinated compounds from the first surface **110** to the second surface **120**. For example, while permeating the gas containing perfluorinated compounds through the catalyst **100**, the differential pressure may be calculated from the pressure measured at the first surface **110** and the pressure measured at the second surface **120**, and the pressure loss may be determined from the calculated differential pressures.

[0112] For example, the improved perfluorinated compound removal efficiency of the catalyst **100** may be maintained.

[0113] According to exemplary embodiments, the catalyst **100** may have a strength reduction rate of 45% or less, 40% or less, 35% or less, 30% or less, 25% or less, 20% or less, 15% or less, 10% or less, 8% or less, or 5% or less, which is defined by Equation 3 below.

$$\text{Strength reduction rate (\%)} = 100 - \{[1 - (S_E/S_I)] \times 100\} \quad [\text{Equation 3}]$$

[0114] In Equation 3, S_E is a strength of the catalyst **100** measured after passing a gas containing perfluorinated compounds for 300 hours, and S_I is a strength of the catalyst **100** measured without passing the gas containing perfluorinated compounds.

[0115] The strength of the catalyst **100** may be measured according to the method known in the art. For example, the strength may be measured by a Brinell hardness test, a Rockwell hardness test, a Vickers hardness test, a Shore hardness test and the like.

[0116] Within the above range, the structure of the catalyst **100** may be maintained for a long period of time, thereby improving the process efficiency for removing the perfluorinated compounds.

[0117] According to exemplary embodiments, the catalyst **100** may have a surface area reduction rate of 75% or less, 70% or less, 60% or less, 50% or less, 45% or less, 43% or less, 40% or less, 30% or less, or 25% or less, which is defined by Equation 4 below.

$$\text{Surface area reduction rate (\%)} = 100 - \left[\left(1 - (A_E/A_I) \right) \times 100 \right] \text{ [Equation 4]}$$

[0118] In Equation 4, A_E is a surface area of the catalyst **100** measured after exposure to 950° C. for 4 hours, and A_I is a surface area of the catalyst **100** measured without exposure to heat.

[0119] Within the above range, the thermal stability of the catalyst **100** may be secured. In addition, even if the catalyst **100** is exposed to a high temperature due to an instantaneous overreaction, the structure may be maintained.

[0120] In exemplary embodiments, a plurality of catalysts **100** may be stacked to form the catalyst assembly **200**.

[0121] FIG. 3 is a schematic cross-sectional view illustrating a reactor including the catalyst assembly **200** according to exemplary embodiments.

[0122] Referring to FIG. 3, the reactor may include a chamber **210** and the catalyst assembly **200** disposed within the chamber **210**. The catalyst assembly **200** in which a plurality of the above-described catalysts are stacked may be disposed within the reactor. In FIG. 3, the catalysts **100** are illustrated separately for the convenience of description, but the plurality of catalysts **100** may be in direct contact with each other.

[0123] According to exemplary embodiments, in the catalysts including the plurality of catalysts **100**, the respective channels may be connected with each other to allow a fluid to pass therethrough.

[0124] For example, the plurality of catalysts **100** may each include the channels having the same diameter, and the second surface **120** of one catalyst **100** and the first surface **110** of another catalyst **100** may be stacked to face each other with being contact each other so that the channels are connected to form the catalyst assembly **200**.

[0125] For example, the lateral faces **150** of the same plurality of catalysts **100** may be adhered to form the catalyst assembly **200**.

[0126] The number of catalysts **100** included in the catalyst assembly **200** is not limited, but may be determined in consideration of the volume of the reactor.

[0127] The gas containing perfluorinated compounds may be injected into one end (e.g., inlet) of the reactor. For example, the gas containing perfluorinated compounds may come into contact with the catalyst assembly **200** in a direction indicated by arrows in FIG. 3, and the gas containing compounds generated by the decomposition of the perfluorinated compounds may be discharged through the other end (e.g., outlet) of the reactor.

[0128] The catalyst assembly **200** including the catalysts according to the above-described embodiments may exhibit the improved perfluorinated compound removal efficiency. In addition, the catalyst assembly **200** may be used continuously and repeatedly.

[0129] According to exemplary embodiments, an initial perfluorinated compound removal efficiency of the catalyst assembly **200** may be 90% or more, 92% or more, or 95% or more.

[0130] According to exemplary embodiments, a long-term perfluorinated compound removal efficiency of the catalyst assembly **200** may be 80% or more, 85% or more, 90% or more, or 92% or more.

[0131] When injecting a gas containing 300 ppm to 700 ppm of perfluorinated compound into the catalyst assembly **200** for 1 hour is set as one cycle, the initial perfluorinated compound removal efficiency may represent a perfluorinated compound removal efficiency within 50 cycles, and the long-term perfluorinated compound removal efficiency may represent a perfluorinated compound removal efficiency within 200 to 500 cycles.

[0132] For example, the removal efficiency of the perfluorinated compound may be calculated according to Equation 5 below.

$$\text{Perfluorinated compound removal efficiency (\%)} = \left[1 - (C_E/C_I) \right] \times 100 \text{ [Equation 5]}$$

[0133] In Equation 5, C_E is a concentration of the perfluorinated compound at an outlet of the reactor, and C_I is a concentration of the perfluorinated compound at an inlet of the reactor.

[0134] The removal efficiency of the perfluorinated compound may represent a removal efficiency at a reaction temperature of 650° C. or higher, or 700° C., unless a separate reaction temperature is described. In general, a high conversion rate of the perfluorinated compound decomposition may be implemented at 700° C. or higher. However, when including the catalyst according to the above-described embodiments, a high conversion rate thereof may be implemented even at a relatively low temperature due to the improvement in gas flowability, the increase in the surface area of the catalyst **100**, and/or the increase in heat transfer efficiency.

[0135] According to exemplary embodiments of the present invention, a method for decomposition of perfluorinated compounds using the above-described catalyst or catalyst assembly is provided.

[0136] According to exemplary embodiments, the catalyst assembly **200** for decomposition of perfluorinated compounds may be prepared. The catalyst assembly **200** may be, for example, an assembly of the above-described catalysts **100**.

[0137] According to exemplary embodiments, the gas containing perfluorinated compounds may be injected into one surface of the catalyst assembly for decomposition of perfluorinated compounds.

[0138] For example, the gas containing perfluorinated compounds and the above-described catalyst or catalyst assembly may be brought into contact with each other in a predetermined reaction temperature range to decompose the perfluorinated compounds.

[0139] Examples of the perfluorinated compounds include completely perfluorinated compounds such as CF_4 , C_2F_6 , C_3F_8 , and C_4F_{10} , etc.; incompletely perfluorinated compounds such as CHF_3 , CH_2F_2 , C_2HF_5 , C_3HF_7 , and C_4HF_9 , etc.; perfluorooctanoic acid, perfluorosulfonic acid, perfluoro-

robutanoic acid, and perfluorononanoic acid, etc. For example, the perfluorinated compounds may include compounds generated in the semiconductor manufacturing process. In one embodiment, the perfluorinated compound may include CF_4 .

[0140] According to exemplary embodiments, the perfluorinated compound may be decomposed at a temperature of 650° C. or higher, 650° C. to 800° C., or 650° C. to 750° C.

[0141] According to exemplary embodiments, a content of the perfluorinated compounds in the gas containing perfluorinated compounds may be 100 ppm to 1,000 ppm, 200 ppm to 900 ppm, 250 ppm to 850 ppm, or 300 ppm to 800 ppm.

[0142] According to exemplary embodiments, the gas containing perfluorinated compounds may include moisture (H_2O). For example, the above-described differential pressure may be calculated by calculating a partial pressure of water vapor.

[0143] According to exemplary embodiments, a content of moisture in the gas containing perfluorinated compounds may be 1% by volume (“vol %”) to 20 vol %, 3 vol % to 17 vol %, 5 vol % to 15 vol %, or 6 vol % to 12 vol %.

[0144] The gas containing perfluorinated compounds may include air as the balance.

[0145] Hereinafter, specific experimental examples are proposed to facilitate understanding of the present invention. However, the following examples are only given for illustrating the present invention and those skilled in the art will obviously understand that various alterations and modifications are possible within the scope and spirit of the present invention. Such alterations and modifications are duly included in the appended claims.

EXAMPLES AND COMPARATIVE EXAMPLES

Example 1

[0146] 100 parts by weight (“wt parts”) of raw material paste was prepared by mixing 70 wt parts of alumina and 30 wt parts of a molding aid and a metal additive including zirconium oxide, zinc oxide, etc. The raw material paste was extrusion molded to prepare a precatalyst having a honeycomb shape including channels with a rectangular cross-section. The precatalyst was sequentially dried and degreased at about 100° C. for 2 hours and about 400° C. for 2 hours.

[0147] Thereafter, the precatalyst was subjected to calcination at a temperature of about 750° C. to prepare a honeycomb-shaped catalyst.

[0148] The catalyst was prepared to have a density of 0.7 kg/L, a porosity of 35, a catalyst material distribution index of 152.25, and a CPSI of 100.

Examples 2 to 4

[0149] Catalysts were prepared according to the same procedures as described in Example 1, except that the density of the catalyst was changed to 0.4 kg/L, 1.0 kg/L and 1.1 kg/L, respectively, by adjusting the condition of extrusion molding, drying condition, calcination condition and the like.

Examples 5 to 8

[0150] Catalyst were prepared according to the same procedures as described in Example 1, except that the porosity according to Equation 1 below was changed to 10, 50.5, 68.8

and 82.3, respectively, by adjusting the condition of extrusion molding, drying condition, calcination condition and the like.

$$\text{Porosity} = (PV/PD) \times 10^4 \quad [\text{Equation 1}]$$

[0151] In Equation 1, PV is a numerical value of the volume of the pores included per unit mass (cm^3/g) of the catalyst, and PD is a numerical value of the average diameter (A) of the pores included in the catalyst.

[0152] The volume of the pores included per unit mass and the average diameter of the pores in the catalyst were measured by nitrogen adsorption method (BET analysis). In addition, the volume of pores and the average diameter of pores were represented as values measured after the prepared catalyst was exposed to 500° C.

Examples 9 to 12

[0153] Catalysts were prepared according to the same procedures as described in Example 1 except that the catalyst material distribution index according to Equation 2 below was changed to 80, 100, 200 and 400, respectively, by adjusting the structure of the honeycomb-shaped catalyst, the condition of extrusion molding, drying condition, calcination condition and the like.

$$\text{Catalyst material distribution index} = \{D \times (L1/L2)\} \times 100 \quad [\text{Equation 2}]$$

[0154] In Equation 2, D is a numerical value of a density (kg/L) of a catalyst material included in the catalyst, L1 is a numerical value of a length (mm) of the channel of the catalyst, and L2 is a numerical value of the shortest distance (corresponding to the thickness of the partition wall 106) between two adjacent channels of the catalyst.

Examples 13 to 17

[0155] Catalysts were prepared according to the same procedures as described in Example 1, except that the structure of the honeycomb-shaped catalyst was adjusted to change the number of channels per square inch (CPSI) to 20, 30, 50, 150 and 200, respectively.

Examples 18 to 21

[0156] Catalysts were prepared according to the same procedures as described in Example 1, except that the content of the alumina was changed to 40 wt %, 50 wt %, 95 wt % and 98 wt %, respectively.

Comparative Example 1

[0157] A catalyst was prepared according to the same procedures as described in Example 1, except that the catalyst was prepared in a pellet shape while having the same content of alumina.

Comparative Example 2

[0158] A catalyst was prepared according to the same procedures as described in Example 1, except that the

catalyst was prepared in a cylinder shape including a through hole ($\phi 3 \pm 0.5$ mm) while having the same content of alumina.

Comparative Example 3

[0159] A catalyst was prepared according to the same procedures as described in Example 1, except that the density of the catalyst was changed to 0.3 kg/L by adjusting the condition of extrusion molding, drying condition, calcination condition and the like.

EXPERIMENTAL EXAMPLE

(1) Evaluation of Perfluorinated Compound Removal Efficiency

[0160] The catalysts according to the examples and comparative examples were processed into a 3-inch cylindrical shape with a volume of 12 L, respectively, and filled into a 3-inch Inconel reaction tube. The reaction temperature was adjusted to 700° C. using an external heater, and a gas containing 500 ppm of perfluorinated compound (tetrafluoromethane (CF₄)) was passed through the Inconel reaction tube for 1 hour. The reactant was analyzed using Fourier transform infrared spectroscopy (FT-IR), and the removal efficiency of the perfluorinated compound was calculated. Specific reaction conditions and the removal efficiency of the perfluorinated compound are as follows, and experimental results are shown in Tables 1 to 5 below.

[Reaction Conditions]

- [0161] i) Air flow rate: 40 L/min
- [0162] ii) Distilled water flow rate: 23 mL/min
- [0163] iii) Space velocity: 2,000/hr

[Perfluorinated Compound Removal Efficiency Calculation Equation]

$$\text{Removal efficiency (\%)} = \{1 - (C_E/C_I)\} \times 100$$

[0164] In the perfluorinated compound removal efficiency calculation equation, C_E is a concentration of the perfluorinated compound at an outlet of the reaction tube, and C_I is a concentration of the perfluorinated compound at an inlet of the reaction tube.

TABLE 1

Item	Density (kg/L)	Perfluorinated compound removal efficiency (initial) (%)
Example 1	0.7	98
Example 2	0.4	97
Example 3	1.0	98
Example 4	1.1	95
Comparative Example 3	0.3	93

TABLE 2

Item	Porosity	Perfluorinated compound removal efficiency (initial) (%)
Example 1	35	98
Example 5	10	92

TABLE 2-continued

Item	Porosity	Perfluorinated compound removal efficiency (initial) (%)
Example 6	50.5	96
Example 7	68.8	97
Example 8	82.3	90

TABLE 3

Item	CPSI	Perfluorinated compound removal efficiency (initial) (%)
Example 1	100	98
Example 13	20	85
Example 14	30	90
Example 15	50	92
Example 16	150	98
Example 17	200	98
Comparative Example 1	(pellet)	95
Comparative Example 2	(cylinder)	90

TABLE 4

Item	Alumina content (wt %)	Perfluorinated compound removal efficiency (initial) (%)
Example 1	70	98
Example 18	40	89
Example 19	50	96
Example 20	95	94
Example 21	98	87

[0165] Referring to Table 1, it was shown that the perfluorinated compound removal efficiency of the catalysts according to the examples was high. In Comparative Example 3 where the catalyst density was low, the perfluorinated compound removal efficiency was decreased. In addition, in Example 4 where the catalyst density was relatively higher than that of the other examples, the perfluorinated compound removal efficiency was relatively decreased.

[0166] Referring to Table 2, in Example 5 where the porosity according to Equation 1 was relatively lower than that of other examples, the perfluorinated compound removal efficiency was relatively decreased. In addition, also in Example 8 where the porosity according to Equation 1 was relatively higher than that of other examples, the perfluorinated compound removal efficiency was relatively decreased.

[0167] Referring to Table 3, the perfluorinated compound removal efficiency of the pellet-shaped or cylinder-shaped catalysts according to the comparative examples was decreased. In addition, in Examples 13 and 14 where CPSI was relatively lower than that of other examples, the perfluorinated compound removal efficiency was decreased.

[0168] Referring to Table 4, in Example 18 where the alumina content was relatively lower than that of other examples, the perfluorinated compound removal efficiency was relatively decreased. In addition, also in Example 21 where the alumina content was relatively higher than that of other examples, the perfluorinated compound removal efficiency was relatively decreased.

(2) Evaluation of Lifespan Characteristics

[0169] A gas containing perfluorinated compounds was passed through the catalyst under the same conditions as (1) above. After repeating for 300 hours, the removal efficiency of the perfluorinated compounds was calculated. Results of the lifespan characteristic evaluation are shown in Tables 5 to 8 below.

TABLE 5

Item	Porosity	Lifespan characteristics evaluation (%)
Example 1	35	98
Example 5	10	50
Example 6	50.5	96
Example 7	68.8	94
Example 8	82.3	60

TABLE 6

Example 12	400	82

TABLE 7

Item	Alumina content (weight %)	Lifespan characteristics evaluation (%)
Example 1	70	98
Example 18	40	82
Example 19	50	94
Example 20	95	90
Example 21	98	60

[0170] Referring to Table 5, in Example 5 where the porosity according to Equation 1 was relatively lower than that of other examples, the lifespan characteristics were decreased. In addition, also in Example 8 where the porosity according to Equation 1 was relatively higher than that of other examples, the lifespan characteristics were decreased.

[0171] Referring to Table 6, in Example 9 where the catalyst material distribution index was relatively lower than that of other examples, the lifespan characteristics were decreased. In addition, also in Example 12 where the catalyst material distribution index was relatively higher than that of other examples, the lifespan characteristics were relatively decreased.

[0172] Referring to Table 7, in Example 18 where the alumina content was relatively lower than that of other examples, the lifespan characteristics were relatively decreased. In addition, also in Example 21 where the alumina content was relatively higher than that of other examples, the lifespan characteristics were decreased.

(3) Evaluation of Strength Reduction Rate

[0173] The strength reduction rate was evaluated according to Equation 3 below. Evaluation results are shown in Tables 9 and 10 below.

$$\text{Strength reduction rate (\%)} = 100 - \left[\left\{ 1 - \left(\frac{SE}{SI} \right) \right\} \times 100 \right] \quad [\text{Equation 3}]$$

[0174] In Equation 3, S_E is a strength of the catalyst measured after passing a gas containing perfluorinated compounds for 300 hours, and S_I is a strength of the catalyst measured without passing the gas containing perfluorinated compounds.

TABLE 8

Item	Porosity	Strength reduction rate evaluation (%)
Example 1	35	6
Example 5	10	15
Example 6	50.5	4
Example 7	68.8	10
Example 8	82.3	11

TABLE 9

Item	Catalyst distribution index	Strength reduction rate evaluation (%)
Example 1	152.25	6
Example 9	80	35
Example 10	100	12
Example 11	200	15
Example 12	400	18

[0175] Referring to Table 8, in Example 5 where the porosity according to Equation 1 was relatively lower than that of other examples, the strength reduction rate of the catalyst was relatively high. In addition, also in Example 8 where the porosity according to Equation 1 was relatively higher than that of other examples, the strength reduction rate of the catalyst was relatively high.

[0176] Referring to Table 9, in Example 9 where the catalyst material distribution index was relatively lower than that of other examples, the strength reduction rate of the catalyst was relatively high.

(4) Evaluation of Pressure Loss

[0177] The pressure loss of the catalyst according to the examples and comparative examples was measured. Specifically, the pressure loss depending on the flow rate per unit area was measured using a pressure gauge based on 90 CMM/m² while injecting the gas in one direction into the catalyst. Measurement results are shown in Table 10 below.

TABLE 10

Item	CPSI	Pressure loss evaluation (mmH ₂ O/mm)
Example 1	100	0.09
Example 13	20	0.01
Example 14	30	0.04
Example 15	50	0.06
Example 16	150	0.18
Example 17	200	0.28
Comparative Example 1	(pellet)	0.40
Comparative Example 2	(cylinder)	0.18

[0178] Referring to Table 10, in Example 17 where CPSI was relatively higher than that of other examples, the

pressure loss was relatively increased. In addition, the pressure loss of the pellet-shaped or cylinder-shaped catalyst according to the comparative examples was increased.

(5) Evaluation of Surface Area Reduction Rate

[0179] The surface area reduction rate of the catalyst according to the examples was evaluated according to Equation 4 below. Evaluation results are shown in Table 11 below.

$$\text{Surface area reduction rate (\%)} = 100 - \left[\left\{ 1 - (A_E/A_I) \right\} \times 100 \right] \quad [\text{Equation 4}]$$

[0180] In Equation 4, A_E is a surface area of the catalyst measured after exposure to 950° C. for 4 hours, and A_I is a surface area of the catalyst measured without exposure to heat.

TABLE 11

Item	Alumina content (wt %)	TABLE area reduction rate (%)
Example 1	70	40
Example 18	40	20
Example 19	50	35
Example 20	95	60
Example 21	98	70

[0181] Referring to Table 11, in Examples 20 and 21 where the content of alumina is relatively higher than that of other Examples, the surface area reduction rate was relatively increased.

What is claimed is:

1. A honeycomb-shaped catalyst for decomposition of perfluorinated compounds, comprising:

a body having a first surface and a second surface facing the first surface, the body having partition walls configured to define a plurality of channels;

the plurality of channels which penetrate the body from the first surface to the second surface of the body; and

wherein the honeycomb-shaped catalyst includes aluminum oxide and the honeycomb-shaped catalyst has a density of 300 g/L or more.

2. The honeycomb-shaped catalyst of claim 1, wherein the honeycomb-shaped catalyst has a density of 400 g/L to 1,000 g/L.

3. The honeycomb-shaped catalyst of claim 1, wherein the honeycomb-shaped catalyst has the number of channels per square inch (CPSI) of 30 to 150.

4. The honeycomb-shaped catalyst of claim 1, wherein the body further includes pores having an average diameter of 50 Å to 300 Å.

5. The honeycomb-shaped catalyst of claim 4, wherein a volume of the pores included per unit mass of the honeycomb-shaped catalyst is 0.2 cm³/g to 0.6 cm³/g.

6. The honeycomb-shaped catalyst of claim 4, wherein the honeycomb-shaped catalyst has a porosity of 10 to 100, which is defined by Equation 1 below:

$$\text{Porosity} = (PV/PD) \times 10^4 \quad [\text{Equation 1}]$$

wherein, in Equation 1, PV is a numerical value of the volume of the pores included per unit mass (cm³/g) of the catalyst, and PD is a numerical value of the average diameter (Å) of the pores included in the catalyst.

7. The honeycomb-shaped catalyst of claim 1, wherein the honeycomb-shaped catalyst has a surface area per unit mass of 40 m²/g or more.

8. The honeycomb-shaped catalyst of claim 1, wherein the honeycomb-shaped catalyst has a catalyst material distribution index of 70 to 500, which is defined by Equation 2 below:

$$\text{Catalyst material distribution index} = \{D \times (L1/L2)\} \times 100 \quad [\text{Equation 2}]$$

wherein, in Equation 2, D is a numerical value of a density (kg/L) of the catalyst, L1 is a numerical value of a length (mm) of the channel of the catalyst, and L2 is a numerical value of the shortest distance (mm) between two adjacent channels of the catalyst.

9. The honeycomb-shaped catalyst of claim 1, wherein a content of the aluminum oxide is 40% by weight to 95% by weight based on a total weight of the catalyst.

10. The honeycomb-shaped catalyst of claim 1, wherein the aluminum oxide comprises at least one of alpha-alumina (α -Al₂O₃), beta-alumina (β -Al₂O₃), gamma-alumina (γ -Al₂O₃), delta-alumina (δ -Al₂O₃), theta-alumina (θ -Al₂O₃) and kappa-alumina (κ -Al₂O₃).

11. The honeycomb-shaped catalyst of claim 1, wherein the honeycomb-shaped catalyst has a strength reduction rate of 45% or less, which is defined by Equation 3 below:

$$\text{Strength reduction rate (\%)} = 100 - \left[\left\{ 1 - (S_E/S_I) \right\} \times 100 \right] \quad [\text{Equation 3}]$$

wherein, in Equation 3, S_E is a strength of the honeycomb-shaped catalyst measured after passing a gas containing perfluorinated compounds for 300 hours, and S_I is a strength of the honeycomb-shaped catalyst measured without passing the gas containing perfluorinated compounds.

12. The honeycomb-shaped catalyst of claim 1, wherein the honeycomb-shaped catalyst has a surface area reduction rate of 75% or less, which is defined by Equation 4 below:

$$\text{Surface area reduction rate (\%)} = 100 - \left[\left\{ 1 - (A_E/A_I) \right\} \times 100 \right] \quad [\text{Equation 4}]$$

wherein, in Equation 4, A_E is a surface area of the honeycomb-shaped catalyst measured after exposure to 950° C. for 4 hours, and A_I is a surface area of the honeycomb-shaped catalyst measured without exposure to heat.

13. A honeycomb-shaped catalyst assembly for decomposition of perfluorinated compounds, comprising a plurality of the honeycomb-shaped catalysts of claim **1**, which are stacked so that channels of the catalysts are connected with each other.

14. A method for removing perfluorinated compounds, the method comprising:

preparing the honeycomb-shaped catalyst assembly of claim **13**; and

injecting a gas containing perfluorinated compounds into one surface of the honeycomb-shaped catalyst assembly for decomposition of perfluorinated compounds.
