Inventor(s)

Or-Bach; Zvi et al.

Multilevel semiconductor device and structure with image sensors and wafer bonding

Abstract

An integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level including an oxide to oxide bond; a plurality of pixel control circuits; a third level disposed underneath the first level, where the third level includes a plurality of third transistors, where the plurality of third transistors each include a single crystal channel; and a plurality of recessed channel transistors.

Background/Summary

CROSS-REFERENCE OF RELATED APPLICATION (1) This application is a continuation-in-part of U.S. patent application Ser. No. 18/432,035 filed on Feb. 4, 2024, which is a continuation-in-part of U.S. patent application Ser. No. 18/382,463 filed on Oct. 20, 2023, now U.S. Pat. No. 11,929,372 issued on Mar. 12, 2024; which is a continuation-in-part of U.S. patent application Ser. No. 18/141,975 filed on May 1, 2023, now U.S. Pat. No. 11,869,915 issued on Jan. 9, 2024; which is a continuation-in-part of U.S. patent application Ser. No. 18/105,881 filed on Feb. 6, 2023, now U.S. Pat. No. 11,855,114 issued on Dec. 26, 2023; which is a continuation-in-part of U.S. patent application Ser. No. 17/951,545 filed on Sep. 23, 2022, now U.S. Pat. No. 11,605,663 issued on Mar. 14, 2023; which is a continuation-in-part of U.S. patent application Ser. No. 17/844,687 filed on Jun. 20, 2022, now U.S. Pat. No. 11,488,997 issued on Nov. 1, 2022; which is a continuation-in-part of U.S. patent application Ser. No. 17/402,527 filed on Aug. 14, 2021, now U.S. Pat. No. 11,404,466 issued on Aug. 2, 2022; which is a continuation-in-part of U.S. patent application Ser. No. 17/317,894 filed on May 12, 2021, now U.S. Pat. No. 11,133,344 issued on Sep. 28, 2021; which is a continuation-in-part of U.S. patent application Ser. No. 17/143,956 filed on Jan. 7, 2021, now U.S. Pat. No. 11,043,523 issued on Jun. 22, 2021, which is a continuation-in-part of U.S. patent application Ser. No. 17/121,726 filed on Dec. 14, 2020, now U.S. Pat. No. 10,978,501 issued on Apr. 13, 2021; which is a continuation-in-part of U.S. patent application Ser. No. 17/027,217 filed on Sep. 21, 2020, now U.S. Pat. No. 10,943,934 issued on Mar. 9, 2021; which is a continuation-in-part of U.S. patent application Ser. No.

16/860,027 filed on Apr. 27, 2020, now U.S. Pat. No. 10,833,108 issued on Nov. 11, 2020; which is a continuation-in-part of U.S. patent application Ser. No. 15/920,499 filed on Mar. 14, 2018, now U.S. Pat. No. 10,679,977 issued on Jun. 9, 2020; which is a continuation-in-part of U.S. patent application Ser. No. 14/936,657 filed on Nov. 9, 2015, now U.S. Pat. No. 9,941,319 issued on Apr. 10, 2018; which is a continuation-in-part of U.S. patent application Ser. No. 13/274,161 filed on Oct. 14, 2011, now U.S. Pat. No. 9,197,804 issued on Nov. 24, 2015; and this application is a continuation-in-part of U.S. patent application Ser. No. 12/904,103 filed on Oct. 13, 2010, now U.S. Pat. No. 8,163,581 issued on Apr. 24, 2012; the entire contents of all of the preceding are incorporated herein by reference.

BACKGROUND OF THE INVENTION

(A) Field of the Invention

(1) This invention describes applications of monolithic 3D integration to various disciplines, including but not limited to, for example, light-emitting diodes, displays, image-sensors and solar cells.

(B) Discussion of Background Art

(2) Semiconductor and optoelectronic devices often require thin monocrystalline (or single-crystal) films deposited on a certain wafer. To enable this deposition, many techniques, generally referred to as layer transfer technologies, have been developed. These include: (A) Ion-cut, variations of which are referred to as smart-cut, nano-cleave and smart-cleave: Further information on ion-cut technology is given in “Frontiers of silicon-on-insulator,” J. Appl. Phys. 93, 4955-4978 (2003) by G. K. Celler and S. Cristoloveanu (“Celler”) and also in “Mechanically induced Si layer transfer in hydrogen-implanted Si wafers,” Appl. Phys. Lett., vol. 76, pp. 2370-2372, 2000 by K. Henttinen, I. Suni, and S. S. Lau (“Henttinen”). (B) Porous silicon approaches such as ELTRAN: These are described in “Eltran, Novel SOI Wafer Technology”, JSAP International, Number 4, July 2001 by T. Yonehara and K. Sakaguchi (“Yonehara”). (C) Lift-off with a temporary substrate, also referred to as epitaxial lift-off: This is described in “Epitaxial lift-off and its applications”, 1993 Semicond. Sci. Technol. 8 1124 by P. Demeester, et al. (“Demeester”). (D) Bonding a substrate with single crystal layers followed by Polishing, Time-controlled etch-back or Etch-stop layer controlled etch-back to thin the bonded substrate: These are described in U.S. Pat. No. 6,806,171 by A. Ulyashin and A. Usenko (“Ulyashin”) and “Enabling SOI-Based Assembly Technology for Three-Dimensional (3D) Integrated Circuits (ICs),” IEDM Tech. Digest, p. 363 (2005) by A. W. Topol, D. C. La Tulipe, L. Shi, S. M. Alam, D. J. Frank, S. E. Steen, J. Vichiconti, D. Posillico, M. Cobb, S. Medd, J. Patel, S. Goma, D. DiMilia, M. T. Robson, E. Duch, M. Farinelli, C. Wang, R. A. Conti, D. M. Canaperi, L. Deligianni, A. Kumar, K. T. Kwietniak, C. D’Emic, J. Ott, A. M. Young, K. W. Guarini, and M. Jeong (“Topol”). (E) Bonding a wafer with a Gallium Nitride film epitaxially grown on a sapphire substrate followed by laser lift-off for removing the transparent sapphire substrate: This method may be suitable for deposition of Gallium Nitride thin films, and is described in U.S. Pat. No. 6,071,795 by Nathan W. Cheung, Timothy D. Sands and William S. Wong (“Cheung”).

Background on Image-Sensors

(3) Image sensors are used in applications such as cameras. Red, blue, and green components of the incident light are sensed and stored in digital format. CMOS image sensors typically contain a photodetector and sensing circuitry. Almost all image sensors today have both the photodetector and sensing circuitry on the same chip. Since the area consumed by the sensing circuits is high, the photodetector cannot see the entire incident light, and image capture is not as efficient.

(4) To tackle this problem, several researchers have proposed building the photodetectors and the sensing circuitry on separate chips and stacking them on top of each other. A publication that describes this method is “Megapixel CMOS image sensor fabricated in three-dimensional integrated circuit technology”, Intl. Solid State Circuits Conference 2005 by Suntharalingam, V., Berger, R., et al. (“Suntharalingam”). These proposals use through-silicon via (TSV) technology where alignment is done in conjunction with bonding. However, pixel size is reaching the 1 μm range, and successfully processing TSVs in the 1 μm range or below is very difficult. This is due to alignment issues while bonding. For example, the International Technology Roadmap for Semiconductors (ITRS) suggests that the 2-4 μm TSV pitch will be the industry standard until 2012. A 2-4 μm pitch TSV will be too big for a sub-1 μm pixel. Therefore, novel techniques of stacking photodetectors and sensing circuitry are required.

(5) A possible solution to this problem is given in “Setting up 3D Sequential Integration for Back-Illuminated CMOS Image Sensors with Highly Miniaturized Pixels with Low Temperature Fully-depleted SOI Transistors,” IEDM, p. 1-4 (2008) by P. Coudrain et al. (“Coudrain”). In the publication, transistors are monolithically integrated on top of photodetectors. Unfortunately, transistor process temperatures reach 600° C. or more. This is not ideal for transistors (that require a higher thermal budget) and photodetectors (that may

prefer a lower thermal budget).

Background on CCD Sensors

(6) Image sensors based on Charge-Coupled Device (CCD) technology has been around for several decades. The CCD technology relies on a collect and shift scheme, wherein charges are collected in individual cells according to the luminosity of the light falling on each of them, then the charges are sequentially shifted towards one edge of the sensor where readout circuits read the sequence of charges one at a time.

(7) The advantage of CCD technology is it has better light sensitivity since almost the entire CCD cell area is dedicated to light collecting, and the control and readout circuits are all on one edge not blocking the light. On the other hand, in a CMOS sensor, the photodiodes in each cell have to share space with the control and readout circuits adjacent to them, and so their size and light sensitivity are therefore limited.

(8) The main issue with CCD technology is this sequential shifting of image information from cell to cell is slow and limits the speed and cell density of CCD image sensors. A potential solution is to put the readout circuits directly under each CCD cell, so that the information is read in parallel rather than in time sequence, thus removing the shifting delay entirely.

Background on High Dynamic Range (HDR) Sensors

(9) Ever since the advent of commercial digital photography in the 1990s, achieving High Dynamic Range (HDR) imaging has been a goal for most camera manufacturers in their image sensors. The idea is to use various techniques to compensate for the lower dynamic range of image sensors relative to the human eye. The concept of HDR however, is not new. Combining multiple exposures of a single image to achieve a wide range of luminosity was actually pioneered in the 1850s by Gustave Le Gray to render seascapes showing both the bright sky and the dark sea. This was necessary to produce realistic photographic images as the film used at that time had extremely low dynamic range compared to the human eye.

(10) In digital cameras, the typical approach is to capture images using exposure bracketing, and then combining them into a single HDR image. The issue with this is that multiple exposures are performed over some period of time, and if there is movement of the camera or target during the time of the exposures, the final HDR image will reflect this by loss of sharpness. Moreover, multiple images may lead to large data in storage devices. Other methods use software algorithms to extract HDR information from a single exposure, but as they can only process information that is recordable by the sensor, there is a permanent loss of some details.

SUMMARY

(11) In another aspect, a method using layer transfer for fabricating a CCD sensor with readout circuits underneath so as to collect image data from each cell in parallel, thus eliminating the shifting delay inherent in the traditional CCD charge transfer sequencing scheme.

(12) In another aspect, a method using layer transfer for fabricating an image sensor consisting of one layer of photo-detectors with small light-sensitive areas, stacked on top of another layer of photo-detectors with larger light-sensitive areas.

(13) In another aspect, a method using layer transfer for fabricating two image sensor arrays monolithically stacked on top of each other with an insulating layer between them and underlying control, readout, and memory circuits.

(14) In another aspect, algorithms for reconstructing objects from images detected by a camera which includes a lens and two image sensor arrays of distinct distances from the lens.

(15) In another aspect, a gesture remote control system using images detected by a camera which includes a lens and two image sensor arrays of distinct distances from the lens.

(16) In another aspect, a surveillance camera system using images detected by a camera which includes a lens and two image sensor arrays of distinct distances from the lens.

(17) In another aspect, a method of constructing a camera which includes a lens and two image sensor arrays of distinct effective distances from the lens, wherein images from the lens are split between the two image sensors by a beam-splitter.

(18) In another aspect, a method of constructing a camera which includes a lens, an image sensor array, and a fast motor, wherein the fast motor actuates the image sensor's position relative to the lens so as to record images from the lens at distinct effective distances from the lens.

(19) In another aspect, a camera system including, a first image sensor array and a second image sensor array wherein the first image sensor array is designed for a first focal plane in front of the camera, and the second image sensor array is designed for a second focal plane in front of the camera, wherein the distance to the first focal plane is substantially different than the distance to the second focal plane.

(20) In another aspect, a camera system including, an image sensor sub system and a memory subsystem and a

control subsystem wherein the camera is designed wherein the image sensor can provide the memory of at least a first image and a second image for the same scene in front of the camera, wherein the first image is for a first focal plane in front of the camera, and the second image is for a second focal plane in front of the camera, wherein the distance to the first focal plane is substantially different than the distance to the second focal plane.

(21) In another aspect, a camera system including, a first image sensor array and a second image sensor array wherein the first image sensor array includes a first mono-crystallized silicon layer, and the second image sensor array includes a second mono-crystallized silicon layer, wherein between the first mono-crystallized silicon layer and second mono-crystallized silicon layer there is a thin isolation layer, wherein through the thin isolation layer there are a multiplicity conducting vias wherein the conducting vias radius is less than 400 nm.

(22) In another aspect, a camera system including, a first image sensor array and a second image sensor array wherein the first image sensor array includes a first mono-crystallized silicon layer, and the second image sensor array includes a second mono-crystallized silicon layer, wherein between the first mono-crystallized silicon layer and second mono-crystallized silicon layer there is a thin isolation layer, wherein the second mono-crystallized silicon layer thickness is less than 400 nm.

(23) In another aspect, an integrated device, the device comprising: a first level comprising a first mono-crystal layer, said first mono-crystal layer comprising a plurality of single crystal transistors and alignment marks; an overlaying oxide on top of said first level; a second level comprising a second mono-crystal layer, said second level overlaying said oxide, wherein said second mono-crystal layer comprises a plurality of first image sensors; and a third level overlaying said second level, wherein said third level comprises a plurality of second image sensors, wherein said second level is aligned to said alignment marks, wherein said second level is bonded to said first level, and wherein said bonded comprises an oxide to oxide bond.

(24) In another aspect, an integrated device, the device comprising: a first level comprising a first mono-crystal layer, said first mono-crystal layer comprising a plurality of single crystal transistors and alignment marks; an overlaying oxide on top of said first level; a second level comprising a second mono-crystal layer, said second level overlaying said oxide, wherein said second mono-crystal layer comprises a plurality of first image sensors; and a third level overlaying said second level, wherein said third level comprises a plurality of second image sensors, and wherein said second level is bonded to said first level.

(25) In another aspect, an integrated device, the device comprising: a first level comprising a first mono-crystal layer, said first mono-crystal layer comprising a plurality of single crystal transistors and alignment marks; an overlaying oxide on top of said first level; a second level comprising a second mono-crystal layer, said second level overlaying said oxide, wherein said second mono-crystal layer comprises a plurality of first image sensors; and a third level overlaying said second level, wherein said third level comprises a plurality of second image sensors, and wherein said second level is bonded to said first level.

(26) In another aspect, an integrated device, the device comprising: a first level comprising a first mono-crystal layer, said first mono-crystal layer comprising a plurality of single crystal transistors; an overlaying oxide on top of said first level; a second level comprising a second mono-crystal layer, said second level overlaying said oxide, wherein said second mono-crystal layer comprises a plurality of first image sensors; and a third level overlaying said second level, wherein said third level comprises a plurality of second image sensors, wherein said second level is bonded to said first level, wherein said bonded comprises an oxide to oxide bond; and an isolation layer disposed between said second mono-crystal layer and said third level.

(27) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first level including a plurality of single crystal transistors; an overlaying oxide on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of first image sensors; and a third level overlaying the second level, where the third level includes a plurality of second image sensors, and where the second level is bonded to the first level.

(28) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, where the first mono-crystal layer includes a plurality of single crystal transistors; an overlying oxide on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide; a third level overlaying the second level, where the third level includes a third mono-crystal layer including a plurality of image sensors, where the second level is bonded to the first level, and where the bonded includes oxide to oxide bonds; and an isolation layer disposed between the second mono-crystal layer and the third level.

(29) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlaying oxide on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide,

(37) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level, where the bonded includes an oxide to oxide bond, and where the integrated device includes a plurality of memory systems.

(38) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level, where the bonded includes an oxide to oxide bond; and a plurality of pixel control circuits, where each of the plurality of image sensors is directly connected to at least one of the plurality of pixel control circuits, and where the integrated device includes a plurality of memory circuits.

(39) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; and a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level, where the bonded includes an oxide to oxide bond, where the integrated device includes a plurality of memory circuits, and where the integrated device includes a plurality of recessed channel transistors.

(40) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; and a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level, where the bonded includes an oxide to oxide bond, and where the integrated device includes a plurality of memory circuits.

(41) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level with an oxide to oxide bond; a plurality of pixel control circuits; a plurality of memory circuits; and a third level disposed underneath the first level, where the third level includes a plurality of third transistors.

(42) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the plurality of image sensors are aligned to the plurality of single crystal transistors with a less than 400 nm alignment error, where the second level is bonded to the first level with an oxide to oxide bond; and a plurality of memory circuits.

(43) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide; a plurality of through layer vias, where a diameter the plurality of through layer vias is less than 400 nm, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level with an oxide to oxide bond; and a plurality of memory circuits.

(44) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level including an oxide to oxide bond; a plurality of pixel control circuits; a third level disposed underneath the first level, where the third level includes a plurality of third transistors, where the plurality of third transistors each include a single crystal channel; and a plurality of memory circuits.

(45) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the plurality of image

sensors are aligned to the plurality of single crystal transistors with a less than 400 nm alignment error, where the second level is bonded to the first level including an oxide to oxide bond; a plurality of memory circuits; and a carrier wafer used for processing of the device.

(46) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide; a plurality of through layer vias, where a diameter of the plurality of through layer vias is less than 400 nm, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level including an oxide to oxide bond; where the plurality of image sensors are aligned to the plurality of single crystal transistors with a less than 400 nm alignment error, and a plurality of memory circuits.

(47) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level including an oxide to oxide bond; a plurality of pixel control circuits; a third level disposed underneath the first level, where the third level includes a plurality of third transistors, where the plurality of third transistors each include a single crystal channel; and a plurality of recessed channel transistors.

(48) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level including an oxide to oxide bond; a plurality of pixel control circuits; a third level disposed underneath the first level, where the third level includes a plurality of third transistors, where the plurality of third transistors each include a single crystal channel; and a plurality of metal gate transistors.

(49) In another aspect, an integrated device, the device including: a first level including a first mono-crystal layer, the first mono-crystal layer including a plurality of single crystal transistors; an overlying oxide disposed on top of the first level; a second level including a second mono-crystal layer, the second level overlaying the oxide, where the second mono-crystal layer includes a plurality of image sensors, where the second level is bonded to the first level including an oxide to oxide bond; a plurality of pixel control circuits; a third level disposed underneath the first level, where the third level includes a plurality of third transistors, where the plurality of third transistors each include a single crystal channel, and where the plurality of image sensors is aligned to the plurality of single crystal transistors with a less than 600 nm alignment error; and a plurality of recessed channel transistors.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

(1) Various embodiments of the invention will be understood and appreciated more fully from the following detailed description, taken in conjunction with the drawings in which:

(2) FIG. 1 illustrates a prior art image sensor stacking technology where connections between chips are aligned during bonding;

(3) FIG. 2 describes two configurations for stacking photodetectors and read-out circuits;

(4) FIG. 3A-3H illustrate an embodiment of this invention, where a CMOS image sensor is formed by stacking a photodetector monolithically on top of read-out circuits using ion-cut technology;

(5) FIG. 4 illustrates the absorption process of different wavelengths of light at different depths in silicon image sensors;

(6) FIG. 5A-5B illustrate an embodiment of this invention, where red, green and blue photodetectors are stacked monolithically atop read-out circuits using ion-cut technology (for an image sensor);

(7) FIG. 6A-6B illustrate an embodiment of this invention, where red, green and blue photodetectors are stacked monolithically atop read-out circuits using ion-cut technology for a different configuration (for an image sensor);

(8) FIG. 7A-7B illustrate an embodiment of this invention, where an image sensor that can detect both visible and infra-red light without any loss of resolution is constructed;

- (9) FIG. **8A** illustrates an embodiment of this invention, where polarization of incoming light is detected;
- (10) FIG. **8B** illustrates another embodiment of this invention, where an image sensor with high dynamic range is constructed;
- (11) FIG. **9** illustrates an embodiment of this invention, where read-out circuits are constructed monolithically above photodetectors in an image sensor;
- (12) FIG. **10A-10B** illustrate a comparison between a typical confocal microscopy technique (prior art) and another confocal microscopy technique with an electronic screen constructed with stacks of modulators;
- (13) FIG. **10C-10G** illustrate an embodiment of this invention where arrays of modulators are monolithically stacked using layer transfer processes;
- (14) FIG. **11A-11B** illustrate the operational processes behind using an array of CCDs as an image sensor (prior art);
- (15) FIG. **11C-11F** illustrate an embodiment of this invention where a CCD sensor is monolithically stacked onto its control circuits using layer transfer, allowing for parallel readout of sensor data;
- (16) FIG. **12A-12D** illustrate an embodiment of this invention where an image sensor with three layers is monolithically stacked, the first layer with photo-detectors of smaller light-sensitive region, the second layer with photo-detectors of larger light-sensitive region, and the third layer with readout circuits to collect sensor data;
- (17) FIG. **13A-13C** illustrate an embodiment of this invention, where two image sensor arrays are monolithically stacked on top of each other with an insulating layer between them using layer transfer processes;
- (18) FIG. **14A-14D** illustrate an embodiment of this invention, where algorithms are described to reconstruct an object at a given distance from the lens imaged by a camera system that includes a lens and two image sensor arrays parallel to each other and to the lens, wherein each sensor array is of distinct distance from the lens;
- (19) FIG. **15A-15C** illustrate an embodiment of this invention, where algorithms are described to reconstruct an object of unknown distance from the lens imaged by a camera system that includes a lens and two image sensor arrays parallel to each other and to the lens, wherein each sensor array is of distinct distance from the lens;
- (20) FIG. **16A-16B** illustrate an embodiment of this invention, where an algorithm is described to reconstruct multiple objects of unknown distances from the lens imaged by a camera system that includes a lens and two image sensor arrays parallel to each other and to the lens, wherein each sensor array is of distinct distance from the lens;
- (21) FIG. **17** illustrates an embodiment of this invention, where a remote control system uses hand gestures which are reconstructed by a camera system that includes a lens and two image sensor arrays parallel to each other and to the lens, where each sensor array is of distinct distance from the lens;
- (22) FIG. **18A-18B** illustrate an embodiment of this invention, where a surveillance system tracks dynamic objects which are reconstructed by a camera system that includes a lens and two image sensor arrays parallel to each other and to the lens, where each sensor array is of distinct distance from the lens. An algorithm is described to time-step through multiple images and subtract images of static objects;
- (23) FIG. **19A** illustrates an embodiment of this invention, where a camera system includes a lens, a beam-splitter and two image sensor arrays wherein images in front of the lens are split by the beam-splitter to the two image sensors wherein each sensor array is of distinct effective distance from the lens; and
- (24) FIG. **19B** illustrates an embodiment of this invention, where a camera system includes a lens, a fast motor and one image sensor array wherein images in front of the lens are detected by the image sensor while it is at two distinct positions relative to the lens within the time duration of interest. The image sensor is actuated back and forth with respect to the lens by the fast motor.

DETAILED DESCRIPTION

(25) Embodiments of the present invention are now described with reference to FIGS. **1-19**, it being appreciated that the figures illustrate the subject matter not to scale or to measure.

NuImager Technology

(26) Layer transfer technology can also be advantageously utilized for constructing image sensors. Image sensors typically include photodetectors on each pixel to convert light energy to electrical signals. These electrical signals are sensed, amplified and stored as digital signals using transistor circuits.

(27) FIG. **1** shows prior art where through-silicon via (TSV) technology is utilized to connect photodetectors **1302** on one layer (tier) of silicon to transistor read-out circuits **1304** on another layer (tier) of silicon.

Unfortunately, pixel sizes in today's image sensors are 1.1 μm or so. It is difficult to get through-silicon vias

with size <1 μm due to alignment problems, leading to a diminished ability to utilize through-silicon via technology for future image sensors. In FIG. 1, essentially, transistors can be made for read-out circuits in one wafer, photodetectors can be made on another wafer, and then these wafers can be bonded together with connections made with through-silicon vias.

(28) FIG. 2-9 describe some embodiments of this invention, where photodetector and read-out circuits are stacked monolithically with layer transfer. FIG. 2 shows two configurations for stacking photodetectors and read-out circuits. In one configuration, denoted as **1402**, a photodetector layer **1406** is formed above read-out circuit layer **1408** with connections **1404** between these two layers. In another configuration, denoted as **1410**, photodetectors **1412** may have read-out circuits **1414** formed above them, with connecting **1416** between these two layers.

(29) FIG. 3A-3H describe an embodiment of this invention, where an image sensor includes a photodetector layer formed atop a read-out circuit layer using layer transfer. In this document, the photodetector layer is denoted as a p-n junction layer. However, any type of photodetector layer, such as a pin layer or some other type of photodetector can be used. The thickness of the photodetector layer is typically less than 5 μm. The process of forming the image sensor could include several steps that occur in a sequence from Step (A) to Step (H). Many of these steps share common characteristics, features, modes of operation, etc. When identical reference numbers are used in different drawing figures, they are used to indicate analogous, similar or identical structures to enhance the understanding of the present invention by clarifying the relationships between the structures and embodiments presented in the various diagrams—particularly in relating analogous, similar or identical functionality to different physical structures.

(30) Step (A) is illustrated in FIG. 3A. A silicon wafer **1502** is taken and a n+ Silicon layer **1504** is ion implanted. Following this, n layer **1506**, p layer **1508** and p+ layer **1510** are formed epitaxially. It will be appreciated by one skilled in the art based on the present disclosure that there are various other procedures to form the structure shown in FIG. 3A. An anneal is then performed to activate dopants in various layers.

(31) Step (B) is illustrated in FIG. 3B. Various elements in FIG. 3B such as **1502**, **1504**, **1506**, **1508** and **1510** have been described previously. Using lithography and etch, a via is etched into the structure shown in FIG. 3A, filled with oxide and polished with CMP. The regions formed after this process are the oxide filled via **1512** and the oxide layer **1514**. The oxide filled via **1512** may also be referred to as an oxide via or an oxide window region or oxide aperture. A cross-section of the structure is indicated by **1598** and a top view is indicated by **1596**. **1516** indicates alignment marks and the oxide filled via **1512** is formed in place of some of the alignment marks printed on the wafer.

Step (C) is illustrated in FIG. 3C. Various elements in FIG. 3C such as **1502**, **1504**, **1506**, **1508**, **1510**, **1512**, **1514**, and **1516** have been described previously. Hydrogen is implanted into the structure indicated in FIG. 3B at a certain depth indicated by dotted lines **1518** of FIG. 3C. Alternatively, Helium can be used as the implanted species. A cross-sectional view **1594** and a top view **1592** are shown.

Step (D) is illustrated in FIG. 3D. A silicon wafer **1520** with read-out circuits (which includes wiring) processed on it is taken, and an oxide layer **1522** is deposited above it.

Step (E) is illustrated in FIG. 3E. The structure shown in FIG. 3C is flipped and bonded to the structure shown in FIG. 3D using oxide-to-oxide bonding of oxide layers **1514** and **1522**. During this bonding procedure, alignment is done such that oxide vias **1512** (shown in the top view **1526** of the photodetector wafer) are above alignment marks (such as **1530**) on the top view **1528** of the read-out circuit wafer. A cross-sectional view of the structure is shown with **1524**. Various elements in FIG. 3E such as **1502**, **1504**, **1506**, **1508**, **1510**, **1512**, **1514**, **1516**, **1518**, **1520**, and **1522** have been described previously.

Step (F) is illustrated in FIG. 3F. The structure shown in FIG. 3E may be cleaved at its hydrogen plane **1518** preferably using a mechanical process. Alternatively, an anneal could be used for this purpose. A CMP process may be then done to planarize the surface resulting in a final n+ silicon layer indicated as **1534**. **1525** depicts a cross-sectional view of the structure after the cleave and CMP process.

(32) Various elements in FIG. 3F such as **1506**, **1508**, **1510**, **1512**, **1514**, **1516**, **1518**, **1520**, **1526**, **1524**, **1530**, **1528**, **1534** and **1522** have been described previously.

(33) Step (G) is illustrated using FIG. 3G. Various elements in FIG. 3G such as **1506**, **1508**, **1510**, **1512**, **1514**, **1516**, **1518**, **1520**, **1526**, **1524**, **1530**, **1528**, **1534** and **1522** have been described previously. An oxide layer **1540** is deposited. Connections between the photodetector and read-out circuit wafers are formed with metal **1538** and an insulator covering **1536**. These connections are formed well aligned to the read-out circuit layer **1520** by aligning to alignment marks **1530** on the read-out circuit layer **1520** through oxide vias **1512**. **1527** depicts a cross-sectional view of the structure.

Step (H) is illustrated in FIG. 3H. Connections are made to the terminals of the photodetector and are indicated

as **1542** and **1544**. Various elements of FIG. **3H** such as **1520**, **1522**, **1512**, **1514**, **1510**, **1508**, **1506**, **1534**, **1536**, **1538**, **1540**, **1542**, and **1544** have been described previously. Contacts and interconnects for connecting terminals of the photodetector to read-out circuits are then done, following which a packaging process is conducted.

(34) FIG. **3A-3G** show a process where oxide vias may be used to look through photodetector layers to observe alignment marks on the read-out circuit wafer below it. However, if the thickness of the silicon on the photodetector layer is <100-400 nm, the silicon wafer is thin enough that one can look through it without requiring oxide vias. A process similar to FIG. **3A-G** where the silicon thickness for the photodetector is <100-400 nm represents another embodiment of this invention. In that embodiment, oxide vias may not be constructed and one could look right through the photodetector layer to observe alignment marks of the read-out circuit layer. This may help making well-aligned through-silicon connections between various layers.

(35) As mentioned previously, FIG. **3A-3G** illustrate a process where oxide vias constructed before layer transfer are used to look through photodetector layers to observe alignment marks on the read-out circuit wafer below it. However, an alternative embodiment of this invention may involve constructing oxide vias after layer transfer. Essentially, after layer transfer of structures without oxide vias, oxide vias whose diameters are larger than the maximum misalignment of the bonding/alignment scheme are formed. This order of sequences may enable observation of alignment marks on the bottom read-out circuit wafer by looking through the photodetector wafer.

(36) While Silicon has been suggested as the material for the photodetector layer of FIG. **3A-G**, Germanium could be used in an alternative embodiment. The advantage of Germanium is that it is sensitive to infra-red wavelengths as well. However, Germanium also suffers from high dark current.

(37) While FIG. **3A-G** described a single p-n junction as the photodetector, it will be obvious to one skilled in the art based on the present disclosure that multiple p-n junctions can be formed one on top of each other, as described in "Color Separation in an Active Pixel Cell Imaging Array Using a Triple-Well Structure," U.S. Pat. No. 5,965,875, 1999 by R. Merrill and in "Trends in CMOS Image Sensor Technology and Design," International Electron Devices Meeting Digest of Technical Papers, 2002 by A. El-Gamal. This concept relies on the fact that different wavelengths of light penetrate to different thicknesses of silicon, as described in FIG. **4**. It can be observed in FIG. **4** that near the surface 400 nm wavelength light has much higher absorption per unit depth than 450 nm-650 nm wavelength light. On the other hand, at a depth of 0.5 μm , 500 nm light has a higher absorption per unit depth than 400 nm light. An advantage of this approach is that one does not require separate filters (and area) for green, red and blue light; all these different colors/wavelengths of light can be detected with different p-n junctions stacked atop each other. So, the net area required for detecting three different colors of light is reduced, leading to an improvement of resolution.

(38) FIG. **5A-5B** illustrate an embodiment of this invention, where red, green, and blue photodetectors are stacked monolithically atop read-out circuits using ion-cut technology (for an image sensor). Therefore, a smart layer transfer technique is utilized. FIG. **5A** shows the first step for constructing this image sensor. **1724** shows a cross-sectional view of **1708**, a silicon wafer with read-out circuits constructed on it, above which an oxide layer **1710** is deposited. **1726** shows the cross-sectional view of another wafer **1712** which has a p+ Silicon layer **1714**, a p Silicon layer **1716**, a n Silicon layer **1718**, a n+ Silicon layer **1720**, and an oxide layer **1722**. These layers are formed using procedures similar to those described in FIG. **3A-G**. An anneal is then performed to activate dopants in various layers. Hydrogen is implanted in the wafer at a certain depth depicted by **1798**. FIG. **5B** shows the structure of the image sensor before contact formation. Three layers of p+pnn+ silicon (each corresponding to a color band and similar to the one depicted in **1726** in FIG. **5A**) are layer transferred sequentially atop the silicon wafer with read-out circuits (depicted by **1724** in FIG. **5A**). Three different layer transfer steps may be used for this purpose. Procedures for layer transfer and alignment for forming the image sensor in FIG. **5B** are similar to procedures used for constructing the image sensor shown in FIGS. **15A-G**. Each of the three layers of p+pnn+ silicon senses a different wavelength of light. For example, blue light is detected by blue photodetector **1702**, green light is detected by green photodetector **1704**, and red light is detected by red photodetector **1706**. Contacts, metallization, packaging and other steps are done to the structure shown in FIG. **5B** to form an image sensor. The oxides **1730** and **1732** could be either transparent conducting oxides or silicon dioxide. Use of transparent conducting oxides could allow fewer contacts to be formed.

(39) FIG. **6A-6B** show another embodiment of this invention, where red, green and blue photodetectors are stacked monolithically atop read-out circuits using ion-cut technology (for an image sensor) using a different configuration. Therefore, a smart layer transfer technique is utilized. FIG. **6A** shows the first step for constructing this image sensor. **1824** shows a cross-section of **1808**, a silicon wafer with read-out circuits

constructed on it, above which an oxide layer **1810** is deposited. **1826** shows the cross-sectional view of another wafer **1812** which has a p+ Silicon layer **1814**, a p Silicon layer **1816**, a n Silicon layer **1818**, a p Silicon layer **1820**, a n Silicon layer **1822**, a n+ Silicon layer **1828** and an oxide layer **1830**. These layers may be formed using procedures similar to those described in FIG. 3A-3G. An anneal is then performed to activate dopants in various layers. Hydrogen is implanted in the wafer at a certain depth depicted by **1898**. FIG. 6B shows the structure of the image sensor before contact formation. A layer of p+pnnpn+ (similar to the one depicted in **1826** in FIG. 6A) is layer transferred sequentially atop the silicon wafer with read-out circuits (depicted by **1824** in FIG. 6A). Procedures for layer transfer and alignment for forming the image sensor in FIG. 6B are similar to procedures used for constructing the image sensor shown in FIG. 3A-3G. Contacts, metallization, packaging and other steps are done to the structure shown in FIG. 6B to form an image sensor. Three different pn junctions, denoted by **1802**, **1804** and **1806** may be formed in the image sensor to detect different wavelengths of light.

(40) FIG. 7A-7B show another embodiment of this invention, where an image sensor that can detect both visible and infra-red light is depicted. Such image sensors could be useful for taking photographs in both day and night settings (without necessarily requiring a flash). This embodiment makes use of the fact that while silicon is not sensitive to infra-red light, other materials such as Germanium and Indium Gallium Arsenide are. A smart layer transfer technique is utilized for this embodiment. FIG. 7A shows the first step for constructing this image sensor. **1902** shows a cross-sectional view of **1904**, a silicon wafer with read-out circuits constructed on it, above which an oxide layer **1906** is deposited. **1908** shows the cross-sectional view of another wafer **1910** which has a p+ Silicon layer **1912**, a p Silicon layer **1914**, a n Silicon layer **1916**, a n+ Silicon layer **1918** and an oxide layer **1920**. These layers may be formed using procedures similar to those described in FIG. 3A-3G. An anneal is then performed to activate dopants in various layers. Hydrogen is implanted in the wafer at a certain depth depicted by **1998**. **1922** shows the cross-sectional view of another wafer which has a substrate **1924**, an optional buffer layer **1936**, a p+ Germanium layer **1926**, a p Germanium layer **1928**, a n Germanium layer **1932**, a n+ Germanium layer **1932** and an oxide layer **1934**. These layers are formed using procedures similar to those described in FIGS. 3A-3G. An anneal is then performed to activate dopants in various layers. Hydrogen is implanted in the wafer at a certain depth depicted by **1996**. Examples of materials used for the structure **1922** include a Germanium substrate for **1924**, no buffer layer and multiple Germanium layers. Alternatively, a Indium Phosphide substrate could be used for **1924** when the layers **1926**, **1924**, **1922** and **1920** are constructed of InGaAs instead of Germanium. FIG. 7B shows the structure of this embodiment of the invention before contacts and metallization are constructed. The p+pnnpn+ Germanium layers of structure **1922** of FIG. 7A are layer transferred atop the read-out circuit layer of structure **1902**. This is done using smart layer transfer procedures similar to those described in respect to FIG. 3A-3G. Following this, multiple p+pnnpn+ layers similar to those used in structure **1908** are layer transferred atop the read-out circuit layer and Germanium photodetector layer (using three different layer transfer steps). This, again, is done using procedures similar to those described in FIG. 3A-3G. The structure shown in FIG. 7B therefore has a layer of read-out circuits **1904**, above which an infra-red photodetector **1944**, a red photodetector **1942**, a green photodetector **1940** and a blue photodetector **1938** are present. Procedures for layer transfer and alignment for forming the image sensor in FIG. 7B are similar to procedures used for constructing the image sensor shown in FIG. 3A-3G. Each of the p+pnnpn+ layers senses a different wavelength of light. Contacts, metallization, packaging and other steps are done to the structure shown in FIG. 7B to form an image sensor. The oxides **1946**, **1948**, and **1950** could be either transparent conducting oxides or silicon dioxide. Use of transparent conducting oxides could allow fewer contacts to be formed.

(41) FIG. 8A describes another embodiment of this invention, where polarization of incoming light can be detected. The p-n junction photodetector **2006** detects light that has passed through a wire grid polarizer **2004**. Details of wire grid polarizers are described in "Fabrication of a 50 nm half-pitch wire grid polarizer using nanoimprint lithography." Nanotechnology 16 (9): 1874-1877, 2005 by Ahn, S. W.; K. D. Lee, J. S. Kim, S. H. Kim, J. D. Park, S. H. Lee, P. W. Yoon. The wire grid polarizer **2004** absorbs one plane of polarization of the incident light, and may enable detection of other planes of polarization by the p-n junction photodetector **2006**. The p-n junction photodetector **2002** detects all planes of polarization for the incident light, while **2006** detects the planes of polarization that are not absorbed by the wire grid polarizer **2004**. One can thereby determine polarization information from incoming light by combining results from photodetectors **2002** and **2006**. The device described in FIG. 8A can be fabricated by first constructing a silicon wafer with transistor circuits **2008**, following which the p-n junction photodetector **2006** can be constructed with the low-temperature layer transfer techniques described in FIG. 3A-3G. Following this construction of p-n junction photodetector **2006**, the wire grid polarizer **2004** may be constructed using standard integrated circuit metallization methods. The

photodetector **2002** can then be constructed by another low-temperature layer transfer process as described in FIG. 3A-3G. One skilled in the art, based on the present disclosure, can appreciate that low-temperature layer transfer techniques are critical to build this device, since semiconductor layers in **2002** are built atop metallization layers required for the wire grid polarizer **2004**. Thickness of the photodetector layers **2002** and **2006** may be preferably less than 5 μm . An example with polarization detection where the photodetector has other pre-processed optical interaction layers (such as a wire grid polarizer) has been described herein. However, other devices for determining parameters of incoming light (such as phase) may be constructed with layer transfer techniques.

(42) One of the common issues with taking photographs with image sensors is that in scenes with both bright and dark areas, while the exposure duration or shutter time could be set high enough to get enough photons in the dark areas to reduce noise, picture quality in bright areas degrades due to saturation of the photodetectors' characteristics. This issue is with the dynamic range of the image sensor, i.e. there is a tradeoff between picture quality in dark and bright areas. FIG. 8B shows an embodiment of this invention, where higher dynamic range can be reached. According the embodiment of FIG. 8B, two layers of photodetectors **2032** and **2040**, could be stacked atop a read-out circuit layer **2028**. **2026** is a schematic of the architecture. Connections **2030** run between the photodetector layers **2032** and **2040** and the read-out circuit layer **2028**. **2024** are reflective metal lines that block light from reaching part of the bottom photodetector layer **2032**. **2042** is a top view of the photodetector layer **2040**. Photodetectors **2036** could be present, with isolation regions **2038** between them. **2044** is a top view of the photodetector layer **2032** and the metal lines **2024**. Photodetectors **2048** are present, with isolation regions **2046** between them. A portion of the photodetectors **2048** can be seen to be blocked by metal lines **2024**. Brighter portions of an image can be captured with photodetectors **2048**, while darker portions of an image can be captured with photodetectors **2036**. The metal lines **2024** positioned in the stack may substantially reduce the number of photons (from brighter portions of the image) reaching the bottom photodetectors **2048**. This reduction in number of photons reaching the bottom photodetectors **2048** helps keep the dynamic range high. Read-out signals coming from both dark and bright portions of the photodetectors could be used to get the final picture from the image sensor.

(43) FIG. 9 illustrates another embodiment of this invention where a read-out circuit layer **2104** is monolithically stacked above the photodetector layer **2102** at a temperature approximately less than 400° C. Connections **2106** are formed between these two layers. Procedures for stacking high-quality monocrystalline transistor circuits and wires at temperatures approximately less than 400° C. using layer transfer are described in pending U.S. patent application Ser. No. 12/901,890, now U.S. Pat. No. 8,026,521, by the inventors of this patent application, the contents of which are incorporated by reference. The stacked layers could use junction-less transistors, recessed channel transistors, repeating layouts or other devices/techniques described in U.S. patent application Ser. No. 12/901,890 the content of which is incorporated by reference. The embodiments of this invention described in FIG. 2-FIG. 9 may share a few common features. They can have multiple stacked (or overlying) layers, use one or more photodetector layers (terms photodetector layers and image sensor layers are often used interchangeably), thickness of at least one of the stacked layers is less than 5 microns and construction can be done with smart layer transfer techniques and are stacking is done at temperatures approximately less than 450° C.

Confocal 3D Microscopy with Screen Made of Stacked Arrays of Modulators

(44) Confocal Microscopy is a method by which 3D image information from a specimen is preserved. Typically, confocal microscopy is used in conjunction with the technique of inducing fluorescence from the specimen by shining laser light upon it. The laser light is absorbed by the specimen which then re-emits the light at a lower energy level (longer wavelength). This secondary light or fluorescence is then imaged by the confocal microscopy system.

(45) FIG. 10A illustrates a side cross-sectional view of a typical microscopy system, wherein the specimen **3600** has been stimulated by laser light (not shown). A lens or lens system **3602** is placed between the specimen and a screen **3604** that has an aperture **3606**. Behind the screen, a photo-detector **3608** detects light that has come through the aperture **3606**. A point on the specimen **3610**, will produce a reciprocal image at the point **3614**, which converges at the aperture **3606**. The light originally from **3610** then passes through the aperture **3606** and subsequently detected by the photo-detector **3608**. Another point on the specimen **3612**, will produce a reciprocal image at the point **3616**, which converges away from the aperture **3606**. Thus, the screen **3604** blocks the light originally from **3612** and so is not sensed by the photo-detector.

(46) By moving the screen and its aperture up, down, left, right, forward, and backward, light from specific points of the specimen are detected and so a 3D image of the specimen can then be reconstructed. Conversely, one may also move the specimen in the same manner instead of the screen to achieve the same objective of

scanning the specimen.

(47) The issue with such a scanning scheme is that mechanical scanning is slow and requires more space to allow for the movements. An alternative is to replace the screen with a 3D array of optical modulators that control the passage of light, thus allowing much faster scanning through electronic control.

(48) FIG. 10B illustrates confocal microscopy system implemented with a fixed 3D array of optical modulators **3620**, where **3600**, **3602**, **3608**, **3610**, **3612**, **3614**, and **3616** are as previously described. The modulators are designed to block and pass the light at a particular wavelength range expected from the fluorescence of the specimen. By turning on certain arrays of modulators along a plane perpendicular to the lens, for example modulator **3624**, which block the light, an effective screen is formed. By leaving the others off, for example modulator **3622**, which let the light through, the position of the electronic screen with respect to the lens can be electronically controlled back and forth. The aperture **3626** is formed by leaving a single modulator on the modulator screen stack turned off to allow light through. The aperture **3626** can then be electronically controlled by the control circuits **3628** to scan through the area of the electronic screen by simple selective turning-off of a single modulator on the plane of the electronic screen.

(49) In such manner, a 3D image can be scanned and reconstructed from the images detected by the electronic scanning of the aperture.

(50) Layer transfer technology may be utilized for constructing the layers for a 3D optical modulator array system. A 3D optical modulator system may contain control circuits, and a stack of optical modulators.

(51) FIGS. 36C-36G illustrate an embodiment of this invention, where the control circuit layer **3630**, and optical modulator layers **3640** and **3660** are stacked monolithically with layer transfer processes. For purposes of illustration, two optical modulator layers are demonstrated here, but the invention is not limited to such, and may contain as many optical modulator layers as needed.

(52) The process of forming the 3D optical modulator array may include several steps that occur in a sequence from Step A to Step E. Many of these steps share common characteristics, features, modes of operation, etc. When identical reference numbers are used in different drawing figures, they are used to indicate analogous, similar or identical structures to enhance the understanding of the present invention by clarifying the relationships between the structures and embodiments presented in the various diagrams—particularly in relating analogous, similar or identical functionality to different physical structures.

(53) Step (A): FIG. 10C illustrates the step for making contacts and interconnects (not shown) for connecting terminals of the optical modulators, such as p contacts **3635** and **3637** and n contacts **3631** and **3633**, to control circuits **3632** in the silicon wafer substrate. Thus control circuit layer **3630** is formed.

(54) Step (B): FIG. 10D illustrates the cross-sectional views of silicon wafer **3642** and silicon wafer **3662** containing optical modulator **3640** and optical modulator **3660** respectively. The optical modulator **3640** may include silicon wafer **3642**, a p-doped Silicon-Germanium (SiGe) layer **3644**, an undoped SiGe layer **3646**, a SiGe Multiple Quantum Well layer **3648**, an undoped SiGe layer **3650**, a n-doped SiGe layer **3652**, and an oxide layer **3654**. These layers may be formed using procedures similar to those described in FIG. 32C. An anneal may then be performed to activate dopants in various layers. Hydrogen may be implanted in the wafer at a certain depth depicted by dashed line **3656**. The optical modulator **3660** may include silicon wafer **3662**, a n-doped Silicon-Germanium (SiGe) layer **3664**, an undoped SiGe layer **3666**, a SiGe Multiple Quantum Well layer **3668**, an undoped SiGe layer **3670**, a p-doped SiGe layer **3672**, and an oxide layer **3674**. These layers may be formed using procedures similar to those described in FIG. 32C. An anneal may then be performed to activate dopants in various layers.

(55) Step (C): FIG. 10E illustrates the two optical modulator layers formed by layer transfer. The optical modulator layer **3640** may be layer transferred atop the silicon wafer **3662** with optical modulator layer **3660** wherein oxide layer **3654** may be bonded to oxide layer **3674**, and the p-SiGe layer **3645** may be a result of the cleave and polish operations. Procedures for layer transfer and alignment for forming the structure in FIG. 10E are similar to procedures used for constructing the optical modulator layer shown in FIG. 32C of parent Ser. No. 13/272,161, now U.S. Pat. No. 9,197,804. An oxide layer **3676** may be deposited on top of the p-SiGe layer **3645**.

(56) Step (D) is illustrated in FIG. 10F. Connections are made to the terminals of the optical modulators by lithographic, etch, and fill operations similar to those described in FIGS. 3A-3G and are indicated as p contacts **3682** and **3684**, and n contacts **3686** and **3688**. Various elements of FIG. 10F such as **3645**, **3646**, **3648**, **3650**, **3652**, **3654**, **3662**, **3664**, **3666**, **3668**, **3670**, **3672**, **3674**, and **3676** have been described previously.

(57) As described previously, FIGS. 3A-3G illustrate a process where oxide vias constructed before layer transfer may be used to look through one optical modulator layers to observe alignment marks on the other optical modulator wafer below it. However, an alternative embodiment of this invention may involve

constructing oxide vias after layer transfer. Essentially, after layer transfer of structures without oxide vias, oxide vias whose diameters are larger than the maximum misalignment of the bonding/alignment scheme may be formed. This order of sequences may enable observation of alignment marks on the bottom control circuit wafer by looking through the optical modulator wafer.

(58) Hydrogen may be implanted in the wafer at a certain depth depicted by dashed line **3689**.

(59) Steps (B)-(D) may be repeated as often as needed to stack as many optical modulator layers as necessary.

(60) Step (E) is illustrated in FIG. **10G**. The two-layer optical modulator stack **3680** may be layer transferred atop the silicon wafer with control circuit layer **3630** to form the structure **3690**, wherein oxide layer **3634** may be bonded to oxide layer **3676**, and the n-SiGe layer **3665** may be a result of the cleave and polish operations. Procedures for layer transfer and alignment for forming the structure in FIG. **10G** are similar to procedures used for constructing the optical modulator layer shown in FIG. **32C** of parent Ser. No. 13/272, 161, now U.S. Pat. No. 9,197,804. An oxide layer **3692** may be deposited on top of the n-SiGe layer **3665**. As previously in Step (C), alignments are made to the terminals of the optical modulators and control circuits to form the connections to the p contacts **3695** and **3696**, and to the n contacts **3697** and **3698**. The functionality of the optical modulators may be tested at this point.

(61) Various elements of FIG. **10G** such as **3632**, **3634**, **3645**, **3646**, **3648**, **3650**, **3652**, **3654**, **3665**, **3666**, **3668**, **3670**, **3672**, **3674**, and **3676** have been described previously.

(62) Persons of ordinary skill in the art will appreciate that while Silicon and Germanium have been suggested as the material for the optical modulator layers of FIG. **10D**, any other appropriate III-V semiconductor material like GaAs, InGaAsP could be utilized. Moreover, the optical modulator layer **3650** is denoted as a p-i-MQW-i-n layer; however, a single quantum well configuration could be used instead of a multiple quantum well configuration such as the shown multiple quantum well layers **3648** and **3668**. Furthermore, the thickness of the optical modulator layer may be typically less than approximately 100 nm, but may also be greater. Thus the invention is to be limited only by the appended claims.

CCD Sensor with Parallel Readout Circuits

(63) The main issue with CCD technology is the sequential shifting of image information from cell to cell is slow and limits the speed and cell density of CCD image sensors. A potential solution is to put the readout circuits directly under each CCD cell, so that the information is read in parallel rather than in time sequence, thus removing the shifting delay entirely.

(64) FIG. **11A** illustrates a typical CCD system; where there is a CCD array **3700** exposed to light, readout circuits **3708**, and connections to the readout circuits **3706**. The movement **3712** of the charges from CCD cell **3702** to CCD cell **3704** and so on is shown for instance.

(65) FIG. **11B** illustrates a typical CCD structure **3720** shown here as a set of three adjacent MOS capacitor devices with corresponding gates **3726**, **3728**, and **3732**. For this demonstration, electrons are chosen as the charges of operation, and so a p-type Si substrate **3722** is used. An incident light generates electron-hole pairs in the p-type Si substrate **3722**. On top of the substrate is an oxide layer **3724**, and above this are three separate gates **3726**, **3728**, **3732**, with respective contacts **3734**, **3736**, **3738**. In this demonstration, by applying negative voltage biases to contacts **3734** and **3738**, electron potential barriers **3742** and **3746** are formed in the p-type Si substrate **3722** underneath gates **3726** and **3732**. By applying positive voltage bias to contact **3736**, an electron potential well **3744** is formed in the p-type Si substrate **3722** underneath gate **3728**. Electrons **3748** can then be collected underneath gate **3728** under these bias conditions. By a time sequence of positive and negative voltage biases on gates **3726**, **3728**, and **3738**, the existence or non-existence of charges under specific gates can be transmitted to adjacent gates by the method known as charge shifting.

(66) Instead of shifting charges one-by-one, the data can be read in parallel by a readout circuit constructed underneath the CCD sensor. Layer transfer technology may be utilized for constructing the layers for a stacked CCD with underlying readout circuits.

(67) FIGS. **11C-11F** illustrate an embodiment of this invention, where the readout circuit layer **3750**, and CCD layer **3760** are stacked monolithically with layer transfer.

(68) The process of forming the CCD-control circuit stack may include several steps that occur in a sequence from Step A to Step D. Many of these steps share common characteristics, features, modes of operation, etc. When identical reference numbers are used in different drawing figures, they are used to indicate analogous, similar or identical structures to enhance the understanding of the present invention by clarifying the relationships between the structures and embodiments presented in the various diagrams—particularly in relating analogous, similar or identical functionality to different physical structures.

(69) Step (A): FIG. **11C** illustrates the step for making contacts, such as contact **3756**, and interconnects (not shown) for connecting the p-type substrate **3762** of the CCD cell to the readout circuits **3752** in the silicon

wafer substrate. Thus readout circuit layer **3750** is formed. Step (B): FIG. **11D** illustrates the cross-sectional view of a Silicon wafer with p-type substrate **3762** and oxide layer **3764**. An implant and anneal process for CCD cell optimization may then be performed to deposit and activate dopants at various sites of the p-type Si substrate **3762**. Hydrogen may be implanted in the wafer at a certain depth depicted by dashed line **3768**.

(70) A connections is made to the p-type Si substrate **3762** by lithographic, etch, and fill operations similar to those described in FIG. **3A-3G** and is indicated here as **3766**.

(71) Step (C) is illustrated in FIG. **11E**. The Si wafer **3760** may be layer transferred atop the silicon wafer with readout circuit layer **3750** to form the structure **3770**, wherein oxide layer **3754** may be bonded to oxide layer **3764**, and the p-Si layer **3763** may be a result of the cleave and polish operations. Alignments are made to the terminals of the p-Si layer **3763** and readout circuit layer **3752** to form the connection **3772** between the two layers.

(72) As described previously, FIG. **3A-3G** illustrate a process where oxide vias constructed before layer transfer may be used to look through one optical modulator layers to observe alignment marks on the other optical modulator wafer below it. However, an alternative embodiment of this invention may involve constructing oxide vias after layer transfer. Essentially, after layer transfer of structures without oxide vias, oxide vias whose diameters are larger than the maximum misalignment of the bonding/alignment scheme may be formed. This order of sequences may enable observation of alignment marks on the bottom control circuit wafer by looking through the optical modulator wafer.

(73) Various elements of FIG. **11E** such as **3752**, **3754**, and **3764** have been described previously.

(74) Step (D) is illustrated in FIG. **11F**, where an oxide layer **3782** is grown on top of the previous stack **3770** to act as a gate dielectric, and gate metal layer **3784** is deposited by using a lithographic mask on the oxide layer **3782** to form the MOS gates of the CCD cells. Thus stacked CCD with underlying readout circuits **3780** may be formed. Various elements of FIG. **11F** such as **3752**, **3754**, **3763**, **3764**, and **3772** have been described previously.

(75) Persons of ordinary skill in the art will appreciate that while Silicon has been suggested as the material for the CCD substrate layers of FIG. **11D**, any other appropriate semiconductor material like Ge, InGaAsP could be utilized. The doping of such material may also vary from p-type to n-type depending on whether the charges to be collected are electrons or holes respectively. Moreover, additional implants and structural modifications may be performed to optimize the charge collection within the substrate. Thus the invention is to be limited only by the appended claims.

Stacked High Dynamic Range (HDR) Sensor

(76) In digital cameras, the typical approach is to capture images using exposure bracketing, and then combining them into a single HDR image. The issue with this is that multiple exposures are performed over some period of time, and if there is movement of the camera or target during the time of the exposures, the final HDR image will reflect this by loss of sharpness. Moreover, multiple images may lead to large data in storage devices. Other methods may use software algorithms to extract HDR information from a single exposure, but as they can only process information that is recordable by the sensor, there is a permanent loss of some details.

(77) A solution may be to use image sensors that have HDR capability. A single layer of photo-detectors within the image sensor is hard-pressed to achieve this. In the case where the light-collecting area is small, the photo-detector is capable of detecting minute amounts of photocurrent but may saturate quicker, whereas when the light-collecting area is large, the photo-detector is capable of handling large amounts of light, but may not be able to detect small photocurrents. Combining them by stacking allows a photo-detector cell to have the capability to detect both low and high luminosity without saturating.

(78) FIG. **12A** illustrates the of stacking smaller photo-detector **3802** which collects less light and is more sensitive than larger photo-detector **3804**, on top of the larger photo-detector **3804** which collects more light and is less prone to saturation than the smaller photo-detector **3802**.

(79) FIG. **12B-12D** illustrate an embodiment of the invention, where layer transfer technology may be utilized for constructing the layers for an HDR image sensor with underlying readout circuits. The process of forming the HDR image sensor may include several steps that may occur in a sequence from Step A to Step C.

(80) Step (A): FIG. **12B** illustrates the first step for constructing this image sensor. Read out silicon wafer **3800** may include read-out circuits **3802** constructed on it, above which an oxide layer **3804** may be deposited.

Silicon wafer structure **3810** may include substrate **3812**, p+ Silicon layer **3814**, p Silicon layer **3816**, n Silicon layer **3818**, n+ Silicon layer **3820** and oxide layer **3822**. These layers may be formed using procedures similar to those described in FIGS. **15A-G**. An anneal may then performed to activate dopants in the layers. Hydrogen may be implanted in the wafer at a certain depth depicted by dashed line **3830**. Another Silicon wafer structure

3840 may include substrate **3842**, p+ Silicon layer **3844**, a p Silicon layer **3846**, n Silicon layer **3848**, n+ Silicon layer **3850** and oxide layer **3852**. These layers may be formed using procedures similar to those described in FIG. 3A-3G. An anneal may then be performed to activate dopants in various layers. Hydrogen may be implanted in the wafer at a certain depth depicted by dashed line **3860**.

(81) Step (B): FIG. 12C illustrates the structure of this embodiment of the invention before contacts and metallization are constructed. The p+pnn+ Silicon layers of Silicon wafer structure **3810** of FIG. 12B may be layer transferred atop the read-out circuit layer of read out silicon wafer **3800**. This may be done using ion-cut layer transfer procedures similar to those described in respect to FIG. 3A-G. Following this, the p+pnn+ silicon layers of another Silicon wafer structure **3840** may be layer transferred atop the Read out silicon wafer **3800** and the p+pnn+ Silicon layers of Silicon wafer structure **3810**. This may be done using procedures similar to those described in FIG. 3A-3G. The structure shown in FIG. 12C therefore has a layer of read-out circuits **3802**, above which a top photo-detector **3811**, and another photo-detector **3841** are present. Procedures for layer transfer and alignment for forming the image sensor in FIG. 12C are similar to procedures used for constructing the image sensor shown in FIG. 3A-3G. Oxide layers **3805** and **3823** may be the results of oxide-to-oxide bonding. p+ Si layers **3815** and **3845** may be results of the cleave and polish operations from the ion-cut layer transfer processes. Various elements of FIG. 12C such as **3802**, **3816**, **3818**, **3820**, **3846**, **3848**, and **3850** have been described previously.

(82) Step (C): FIG. 12D illustrates the process performed on the top photo-detector **3811** to reduce its effective image sensor cell area. The edges of top photo-detector **3811** may be lithographically defined, etched, then filled with oxide, which is transparent to visible light. n+ Si layer **3860**, n Si layer **3862**, p Si layer **3864**, p+ Si layer **3866**, and oxide layers **3870** and **3872** may be results of this processing, thus forming small photo-detector **3899**. Various elements of FIG. 12D such as **3802**, **3805**, **3815**, **3816**, **3818**, **3820**, and **3823** have been described previously. Contacts, metallization, packaging and other steps (not shown) as described elsewhere herein may done to the structure shown in FIG. 12D to form the HDR image sensor. The three mono-crystalline silicon layers, small photo-detector **3899**, large photo-detector **3899**, and read-out circuits **3802**, may be electrically connected by conducting vias that may have a radius less than about 400 nm due to the thin layers being layer transferred. This may be accomplished with processing described herein and in US patent application 2011/0121366.

(83) Persons of ordinary skill in the art will appreciate that while Silicon has been suggested as the material for the HDR photo-detector layers of FIG. 12D, any other appropriate semiconductor material like Ge, could be utilized. Moreover, additional implants and structural modifications may be performed to optimize the charge collection within the photo-detectors. Thus the invention is to be limited only by the appended claims.

2-Sensor Camera System

(84) FIG. 13A-13B illustrate an embodiment of the invention, where layer transfer technology may be utilized for constructing the layers for an image sensor chip that may include two image sensor arrays in parallel planes to each other with an isolation layer between each of the two image sensor arrays, and between the two image sensor arrays and the underlying readout/control circuits. The process of forming the two-image sensor chip may include several steps that may occur in a sequence from Step A to Step B.

(85) Step (A): FIG. 13A illustrates the first step for constructing the image sensor chip. Read-out circuit layer structure **4000** may include a mono-crystalline silicon wafer with readout/control circuits **4002** constructed on it, above which an oxide layer **4004** may be deposited. Structure **4010** may include another mono-crystalline silicon wafer with substrate **4012**, p+ Silicon layer **4014**, p Silicon layer **4016**, n Silicon layer **4018**, n+ Silicon layer **4020** and oxide layer **4022**. These layers may be formed using procedures similar to those described in FIG. 3A-3G. An anneal may be performed to activate dopants. Hydrogen may be implanted into p+ Silicon layer **4014** at a certain depth depicted by dashed line **4030**. Layer structure **4040** may include another mono-crystalline silicon wafer with substrate **4042**, p+ Silicon layer **4044**, a p Silicon layer **4046**, n Silicon layer **4048**, n+ Silicon layer **4050** and oxide layer **4052**. These layers may be formed using procedures similar to those described in FIG. 3A-3G. An anneal may be performed to activate dopants. Hydrogen may be implanted in p+ Silicon layer **4044** at a certain depth depicted by dashed line **4060**.

(86) Step (B): FIG. 13B illustrates the structure of the embodiment of the invention before contacts and metallization are constructed. The p+pnn+ Silicon layers of structure **4010** of FIG. 13B may be layer transferred atop the read-out circuit layer structure **4000**. This may be done using smart layer transfer procedures similar to those described in respect to FIG. 3A-3G. Following this, the p+pnn+ silicon layers of layer structure **4040** may be layer transferred atop the read-out circuit layer structure **4000** layer and the p+pnn+ Silicon layers of structure **4010**. This may be done using procedures similar to those described in FIGS. 15A-G. The structure shown in FIG. 13B therefore has a layer of read-out circuits **4002**, above which a

photo-detector back image sensor **4011**, and another photo-detector front image sensor **4041** may be present. Procedures for layer transfer and alignment for forming the image sensor in FIG. **13B** are similar to procedures used for constructing the image sensor shown in FIG. **3A-3G**. Oxide layers **4005** and **4023** may be the results of oxide-to-oxide bonding and the ion-cut processing. In addition, oxide layer **4023** may form the isolation layer separating back image sensor **4011** and front image sensor **4041** and may require careful calibration of its thickness, which may range from about 10 micro-meters to about 400 micro-meters. The material for the isolation layer may be chosen such that it has a large enough bandgap that will let substantially all wavelengths of visible light through to the back image sensor **4011**. p+ Si layers **4015** and **4045** may be results of the cleave and polish operations from the layer transfer processes. Various elements of FIG. **13C** such as **4002**, **4016**, **4018**, **4020**, **4046**, **4048**, and **4050** have been described previously. Thus image sensor chip **4099** is formed. Back image sensor **4011** and front image sensor **4041** may each have thicknesses of less than about 2 microns, less than about 1 micron, less than about 400 nm and/or less than about 200 nm. Front image sensor **4041** may typically be thinner than back image sensor **4011**. Base wafer substrate **4012** and substrate **4042** may be reused to create portions of another or additional image sensor chip.

(87) FIG. **13C** illustrates a method by which pixel alignment between the two sensor arrays may be checked. A laser device **4074** projects a laser beam **4076** with a diameter smaller than the size of the pixel elements of front image sensor **4070** and back image sensor **4072**. The laser beam **4076** may be of a wavelength that is detectable by that of the front image sensor **4070** and back image sensor **4072**, and may be in a direction perpendicular to the two sensors. A particular photo-detector **4078** on front image sensor **4070** detects the laser beam **4076**. As only part of the laser beam **4076** may be absorbed, the remainder will continue onto photo-detector **4080** on back image sensor **4072** which detects the attenuated laser beam **4076**. If the location of photo-detector **4078** on front image sensor **4070** corresponds to the location of photo-detector **4080** on back image sensor **4072**, they are determined to be in alignment. Otherwise, adjustments on one of the image sensors may be performed to achieve alignment. The process may be repeated for a sampling of more photo-detector sites throughout the image sensors **4070** and **4072** where the chosen sites may be near the edges of the front image sensor **4070** and back image sensor **4072**, and may form the vertices of a triangle, square or other polygons as to ensure that alignment is guaranteed throughout front image sensor **4070** and back image sensor **4072**. The alignment process may also be used to determine an accurate measure of the distance between the two sensors by timing the arrival of the laser light, which may be pulsed, onto each of the sensors.

(88) Persons of ordinary skill in the art will appreciate that while Silicon has been suggested as the material for the photo-detector layers of FIG. **13A-13B**, any other appropriate semiconductor material such as, for example, Ge, could be utilized. For example, materials with different bandgaps could be used for each of the image sensor arrays so as to have sensitivities to different optical spectra or optical spectrum. Furthermore, the geometric structure of the photo-detectors may also be altered independently so as to allow each one to have different optical intensity saturation levels. Moreover, additional implants and structural modifications may be performed to optimize the charge collection within the photo-detectors. Further, adjustments in the alignment of the photo-detectors may be performed virtually, as part of a software program and memory with offsets. Thus the invention is to be limited only by the appended claims.

(89) FIG. **14A** illustrates an embodiment of the invention, where an imaging system **4110** may include a lens **4112** with focal length f and aperture of size R , a front image sensor **4113** set at distance z_2 from the lens **4112** on its image side (the location of which corresponds to the image focal plane of another plane **4117** at distance d_2 from the lens **4112** on its real side), a back image sensor **4114** set at a distance z_1 from the lens **4112** on its image side (the location of which corresponds to the image focal plane of another plane **4116** at distance d_1 from the lens **4112** on its real side). The real workspace on the real side of the lens **4112** may be bounded by the plane **4116** and plane **4117** at distances d_1 and d_2 respectively from the lens **4112** on the real side. The images collected from front image sensor **4113** and back image sensor **4114** may be processed and stored by an integrated image processor and memory system **4106**, which may be connected to the image sensor arrays front image sensor **4113** and back image sensor **4114**. For example, a plane or slice **4111** of a scene in the workspace bounded by plane **4117** and plane **4116** may have a corresponding image focal plane **4115** on the image side of lens **4112**, which may lie between front image sensor **4113** and back image sensor **4114**. Front image sensor **4113** and back image sensor **4114** may be parallel with respect to each other. The term imaging system may also be referred to as a camera system, or an optical imaging system, herein.

(90) For reconstructing images on planes on either side of the lens **4112**, image mapping may be performed using algorithms from Fourier optics utilizing the Fourier transform, available through commercial packages such as the MATLAB Image Processing Toolbox. It will be useful to recall here the Lens-maker's equation which states that for an object on a plane at a distance o from a lens of focal length f where $f < o$, the focal

image plane of the object will lie at a distance i on the opposite side of the lens according to the equation:
 $1/o+1/i=1/f$.

(91) For the image reconstruction algorithms discussed herein, the following notations will be used:

(92) d :=distance from lens on real side

(93) d_0 :=initial distance from lens on real side

(94) z :=distance from lens on image side

(95) s :=space step interval

(96) $f(s)$:=nonlinear step interval e.g. $f(s)=s\{\text{circumflex over ()}\}^n$

(97) t :=time

(98) t_0 :=starting time

(99) ts :=time step interval

(100) $S_1(i,j)$:=matrix data of image detected on front image sensor **4113**

(101) $S_2(i,j)$:=matrix data of image detected on back image sensor **4114**

(102) $O(i,j)$:=reconstructed image from S_1 and S_2

(103) $OS(i,j)$:=stored reconstructed data $O(i,j)$

(104) $S_1(i,j,t)$:=stored matrix data of image detected on front image sensor **4113** at time t

(105) $S_2(i,j,t)$:=stored matrix data of image detected on back image sensor **4114** at time t

(106) $FIM(O, d, z)$:=forward image mapping (FIM) operation from an image O on the real side of the lens **4312** at distance d from lens **4312** to the image side of the lens **4312** at a distance z from lens **4312**

(107) $BIM(O, d, z)$:=backward image mapping (BIM) operation from an image O on the image side of the lens **4312** at distance z from lens **4312** to the real side of the lens **4312** at a distance d from lens **4312**

(108) $I_1(i,j,d,z_1)$:=FIM operation of object matrix upon $S_1(i,j)$ at specified d , and $z=z_1$

(109) $I_2(i,j,d,z_2)$:=FIM operation of object matrix upon $S_2(i,j)$ at specified d , and $z=z_2$

(110) $IS_1(i,j)$:=stored I_1 data

(111) $IS_2(i,j)$:=stored I_2 data

(112) $O_1(i,j,d,z_1)$:=BIM operation on $S_1(i,j)$ at specified d , $z=z_1$

(113) $O_2(i,j,d,z_2)$:=BIM operation on $S_2(i,j)$ at specified d , and $z=z_2$

(114) $O_{diff}(i,j)$:= $O_1(i,j,d,z)-O_2(i,j,d,z)$ for every i, j

(115) $O_{diff}(i,j,k)$:= $O_1(i,j,d,z)-O_2(i,j,d,z)$ for every i, j with k as the iteration variable if values are to be stored

(116) $ABS[a]$:=absolute value operation on a scalar a

(117) $NORM[A]$:= A matrix norm operation (for example, a 2-norm)

(118) $GET_SHARP[A]$:=extract object within image data that exhibits the most contrast compared to its surroundings.

(119) T :=error tolerance between the corresponding elements of 2 matrices

(120) E :=error tolerance of any scalar comparison

(121) $FFT(M)$:=fast fourier transform operation on a matrix M

(122) $IFFT(M)$:=inverse fast fourier transform operation on a matrix M

(123) $OF(i,j)$:= $O(i,j)$ in Fourier space

(124) $OF_1(i,j)$:= $O_1(i,j)$ in Fourier space

(125) $OF_2(i,j)$:= $O_2(i,j)$ in Fourier space

(126) $OF_{diff}(i,j)$:= $OF_1(i,j,d,z)-OF_2(i,j,d,z)$ for every i, j

(127) FIG. 14B illustrates an algorithm by which a plane of distance d from the lens **4112** is chosen

(128) by the viewer and the image on that plane may be reconstructed and is outlined here as Algorithm **41A**:

(129) Step A (**4140**): choose $d > f$, $d_1 \leq d \leq d_2$

(130) Step B (**4142**): calculate z from d using the lens-maker's formula

(131) Step C (**4144**): O_1 and O_2 are calculated by BIM operations on S_1 and S_2 respectively

(132) Step D (**4146**): Calculate O_{diff} := O_1-O_2 for every element in the matrices O_1 and O_2

(133) Step E (**4148**): Calculate the linear distance weighted estimate of the reconstructed object $O(i,j)$ as expressed by:

(134) For every i,j :

(135)
If $ABS[O_{diff}(i,j)] < T$, then $O(i,j) = O_1(i,j,d,z) \times (z_1 - z) / (z_1 - z_2) + O_2(i,j,d,z) \times (z - z_2) / (z_1 - z_2)$, (F)
else $O(i,j) = 0$. (G)

(136) FIG. 14C illustrates another algorithm by which a plane of distance d from the lens **4112** is chosen by the viewer and the image on that plane may be transformed in Fourier space, reconstructed, then transformed back

in real space, and is outlined here as Algorithm 41B:

(137) Step A (**4160**): choose $d > f$, $d_1 \leq d \leq d_2$

(138) Step B (**4162**): calculate z from d using the lens-maker's formula

(139) Step C (**4164**): O_1 and O_2 are calculated by BIM operations on S_1 and S_2 respectively

(140) Step D (**4166**): OF_1 and OF_2 are calculated by FFT operations on O_1 and O_2 respectively

(141) Step E (**4168**): $OF_{diff} = OF_1 - OF_2$ is calculated for every element in the matrices OF_1 and OF_2

(142) Step F (**4170**): Calculate the linear distance weighted estimate of the reconstructed object $OF(i,j)$ in Fourier space as expressed by:

(143) For every i,j :

(144) If $ABS[OF_{diff}(i,j)] < T$, then $OF(i,j) = OF_1(i,j,d,z) \times (z_1 - z) / (z_1 - z_2) + OF_2(i,j,d,z) \times (z - z_2) / (z_1 - z_2)$, (H)
else $OF(i,j) = 0$. Step G (4172): $O(i,j)$ is extracted in real space by performing the *IFFT* operation on $OF(i,j)$ (I)

(145) FIG. 14D illustrates an iterative algorithm by which the workspace may be reconstructed using planes at intervals of the distance d from the lens **4112** between d_1 and d_2 . A stepping algorithm may be performed wherein d marches from d_1 towards d_2 which may use nonlinear intervals such as a geometric relationship. Upon completion, the cycle may be repeated and the reconstructed image of a plane at a particular d is compared to the image of the same plane from the previous cycle. If the difference between these two images is within some error tolerance, then the set of images from that particular cycle may be accepted as the reconstruction of the workspace. Otherwise, the cycle may continue through another iteration. The algorithm is outlined here as Algorithm 41C:

(146) Step A (**4180**): Start with $d = d_0$, $d_1 \leq d_0 \leq d_2$, initialize IS_1 , IS_2 as zero matrices

(147) Step B (**4181**): Use Algorithm 41A or Algorithm 41B to calculate $O(i,j)$

(148) Step C (**4182**): Check if $d = d_0$, if yes go to Step D otherwise continue to Step E

(149) Step D (**4183**): Store $O(i,j)$ into $OS(i,j)$

(150) Step E (**4184**): Calculate I_1 and I_2 by FIM operations on $O(i,j)$

(151) Step F (**4185**): Take I_1 and I_2 out from sensor data S_1 and S_2 respectively.

(152) Step G (**4186**): Add stored data IS_1 and IS_2 (I_1 and I_2 from previous step) to sensor data S_1 and S_2 respectively.

(153) Step H (**4187**): Store current I_1 and I_2 into IS_1 and IS_2 respectively.

(154) Step I (**4188**): Increment d by some interval function such as a geometric relationship.

(155) Step J (**4189**): If d has not exceeded d_2 , loop back to Step B (**4181**) and continue from there

(156) Step K (**4190**): If d has exceeded d_2 , reset $d = d_0$

(157) Step L (**4191**): Use Algorithm 41A or Algorithm 41B to calculate $O(i,j)$

(158) Step M (**4192**): Compare $O(i,j)$ with $OS(i,j)$ using a matrix norm operation, and if within error tolerance, algorithm ends. Else algorithm loops back to Step C (**4182**) and continues on.

(159) FIG. 15A illustrates an embodiment of the invention, where an imaging system **4210** may include a lens **4212** with focal length f and aperture of size R , a front image sensor **4213** set at distance z_2 from the lens **4212** on its image side (the location of which corresponds to the image focal plane of another plane **4217** at distance d_2 from the lens **4212** on its real side), a back image sensor **4214** set at distance z_1 from the lens **4212** on its image side (the location of which corresponds to the image focal plane of another plane **4216** at distance d_1 from the lens **4212** on its real side). The real workspace on the real side of the lens **4212** may be bounded by plane **4216** and plane **4217** at distances d_1 and d_2 respectively from the lens **4212** on the real side. A distinct object **4211** lies on a plane at an unknown distance d from the lens **4212**, and assuming a general situation where d is neither equal to d_1 nor d_2 , the images of the object **4211** on front image sensor **4213** and back image sensor **4214** will not be in sharp focus (blurred), and the object's image focal plane **4215** will lie between the sensor planes, front image sensor **4213** and back image sensor **4214**. The images may be processed and stored by an integrated image processor and memory system **4206** connected to the image sensor arrays front image sensor **4213** and back image sensor **4214**. Front image sensor **4213** and back image sensor **4214** may be parallel with respect to each other.

(160) FIG. 15B illustrates an algorithm by which a single distinct object of unknown distance d

(161) from the lens **4212** is present and its image may be reconstructed. Determination of distance d of the object **4211** may be achieved through a marching algorithm searching for the minimum of $O_{diff}(i,j)$ indicating best match, and is outlined here as Algorithm 42A:

(162) Step A (**4240**): starting $d = d_0$ is chosen, $d_1 \leq d_0 \leq d_2$

(163) Step B (**4242**): calculate z from d using the lens-maker's formula

(164) Step C (**4244**): O1 and O2 are calculated by BIM operations on S1 and S2 respectively
(165) Step D (**4246**): Odiff:=O1-O2 is calculated for every element in the matrices O1 and O2
(166) Step E (**4248**): NORM operation is performed on Odiff
(167) Step F (**4250**): If the result of the NORM operation reveals a minimum,
(168) then
(169) Step G (**4252**): d* is found and z* is calculated,
(170) else
(171) Step H (**4254**): d is incremented by s and the steps B-F are repeated.
(172) Step I (**4256**): Calculate the linear distance weighted estimate of the reconstructed object O(i,j) as expressed by:
(173) For every i,j:
(174)
If $ABS[Odiff(i,j)] < T$, then $O(i,j) = O1(i,j,d,z) \times (z1 - z) / (z1 - z2) + O2(i,j,d,z) \times (z - z2) / (z1 - z2)$, (J)
else $O(i,j) = 0$. (K)
(175) FIG. 15C illustrates another algorithm by which a single distinct object of unknown distance d from the lens **4212** is present and its image may be reconstructed. Determination of distance d of the object **4211** may be achieved through a marching algorithm searching for the maximum sharpness of O1(i,j) indicating best match. Sharpness may be calculated by any of known methods such as contrast and high-frequency content calculations. The algorithm is outlined here as Algorithm 42B:
(176) Step A (**4260**): starting d=d0 is chosen, $d1 \leq d0 \leq d2$
(177) Step B (**4262**): calculate z from d using the lens-maker's formula
(178) Step C (**4264**): O1 is calculated by BIM operation on S1
(179) Step D (**4266**): Sharpness value of O1 is calculated and stored in OS
(180) Step E (**4268**): If a sharpness maximum is found,
(181) then Step F (**4270**): d* is determined and z* is calculated
(182) else
(183) Step G (**4272**): d is incremented by s and steps B-E are repeated.
(184) Step H (**4274**): O2 is calculated using BIM operation on S2 with d* and z*
(185) Step I (**4276**): Odiff:=O1-O2 is calculated for every element in the matrices O1 and O2
(186) Step J (**4278**): Calculate the linear distance weighted estimate of the reconstructed object O(i,j) as expressed by:
(187) For every i,j:
(188)
If $ABS[Odiff(i,j)] < T$, then $O(i,j) = O1(i,j,d,z) \times (z1 - z) / (z1 - z2) + O2(i,j,d,z) \times (z - z2) / (z1 - z2)$, (L)
else $O(i,j) = 0$. (M)
(189) FIG. 16A illustrates an embodiment of the invention, where an imaging system **4310** may include a lens **4312** with focal length f and aperture of size R, a front image sensor **4313** set at distance z2 from the lens **4312** on its image side (the location of which corresponds to the image focal plane of another plane **4317** at distance d2 from the lens **4312** on its real side), a back image sensor **4314** set at distance z1 from the lens **4312** on its image side (the location of which corresponds to the image focal plane of another plane **4316** at distance d1 from the lens **4312** on its real side). The real workspace on the real side of the lens **4312** may be bounded by plane **4316** and plane **4317** at distances d1 and d2 respectively from the lens **4312** on the real side. Multiple distinct objects **4311**, **4318**, **4319** lie on a plane at unknown distances d, d4, d5 from the lens **4312**. For example, distinct object **4311** in the workspace bounded by plane **4317** and plane **4316** may have a corresponding image focal plane **4315** on the image side of lens **4312**, which may lie between front image sensor **4313** and back image sensor **4314**. The images may be processed and stored by an integrated image processor and memory system **4306** connected to the image sensor arrays front image sensor **4313** and back image sensor **4314**. Front image sensor **4313** and back image sensor **4314** may be parallel with respect to each other.
(190) FIG. 16B illustrates an algorithm by which multiple distinct objects of unknown distances d, d4, d5 from the lens **4312** are present and their images may be successively reconstructed. Reconstruction of the objects may be achieved through a marching algorithm searching for each object from near to far from the lens in succession and performing an image subtraction operation after each object is found. The algorithm is outlined here as Algorithm 43A:

(191) Step A (**4340**): starting $d=d_0$ is chosen

(192) Step B (**4342**): calculate z from d using the lens-maker's formula

(193) Step C (**4344**): Use algorithms 41A, 42A or 42B to find nearest object.

(194) Step D (**4346**): If no object is found, algorithm stops.

(195) Step E (**4348**): If object is found, the GET_SHARP operation is performed to extract image of only the object OC from O

(196) Step F (**4350**): I1 and I2 are calculated by FIM operations on OC upon front image sensor **4313** and back image sensor **4314** respectively: $I1=FIM(OC, d, z1)$, $I2=FIM(OC, d, z2)$

(197) Step G (**4352**): The sensor image data S1 and S2 are updated by subtracting I1 and I2 respectively.

(198) Step H (**4354**): d is incremented to look for the next object.

(199) FIG. 17 illustrates an embodiment of the invention, where an imaging system **4410** may be set up as a gesture control system including a lens **4412** with focal length f and aperture of size R , a front image sensor **4413** set at distance $z2$ from the lens **4412** on its image side (the location of which corresponds to the image focal plane of another plane **4417** at distance $d2$ from the lens **4412** on its real side), a back image sensor **4414** set at distance $z1$ from the lens **4412** on its image side (the location of which corresponds to the image focal plane of another plane **4416** at distance $d1$ from the lens **4412** on its real side). The real workspace on the real side of the lens **4412** may be bounded by plane **4416** and plane **4417** at distances $d1$ and $d2$ respectively from the lens **4412** on the real side. An isolated hand **4411** or similar such object may be placed within the real workspace, and may be isolated from other objects within the real space by, for example, a technique using a glove over the hand with a specific color and using a filter gel over the lens with the same color as the glove. Isolated hand **4411** may have a corresponding image focal plane **4415** on the image side of lens **4412**, which may lie between front image sensor **4413** and back image sensor **4414**. At a fixed time t , isolated hand **4411** will then practically lie on the plane at some unknown distance d from the lens, and Algorithm 42A or Algorithm 42B may be used to reconstruct an image of the isolated hand **4411**. An image recognition program may be used to recognize the gesture of the isolated hand **4411** at this point in time and a specific action that may be remote to the position of the isolated hand may be controlled accordingly. Time-stepping through multiple images of the isolated hand **4411** may allow a series of remote commands to be relayed or a combining of multiple gestures to relay a more complicated remote command. The images may be processed and stored by an integrated image processor and memory system **4406** connected to the image sensor arrays front image sensor **4413** and back image sensor **4414**. Front image sensor **4413** and back image sensor **4414** may be parallel with respect to each other.

(200) FIG. 18A illustrates an embodiment of the invention where a system similar to imaging system **4210** in FIG. 15A may be used in a surveillance camera system wherein by time-stepping through the image data recorded by the front image sensor **4213** and back image sensor **4214**, static objects may be removed from the data and dynamic objects may be isolated and tracked. Algorithm 42A or Algorithm 42B may then be used at each time-step to reconstruct the image of the moving object. The desired time-step may typically be determined as the inverse of the frame rate of the camera recording. For example, Scene 1 **4510** on front image sensor **4213** may show at time $t=t_0$ static objects building **4512** and tree **4514**. Scene 2 **4520** on front image sensor **4213** shows at time $t=t_0+t_s$ (the next time step t_s after t_0) static objects building **4512** and tree **4514**, and new object, person **4516**. The data S1 from the front image sensor **4213** that will be used for image reconstruction may then be updated by subtracting the difference between Scene 2 **4520** and Scene 1 **4510** to form differential scene **4530**, thus removing static objects building **4512** and tree **4514**, and leaving just dynamic object person **4516**. Similar steps may be applied to back image sensor **4214**.

(201) Algorithm 42A or Algorithm 42B may then be applied to differential scene **4530** to reconstruct the image. If multiple dynamic objects are present in the scene, Algorithm 43A may be used to track and reconstruct the objects.

(202) FIG. 18B illustrates an algorithm by which a surveillance camera system through time-stepping may track and reconstruct multiple distinct dynamic objects of unknown distances from the lens. The algorithm is outlined here as Algorithm 45:

(203) Step A (**4540**): Start at $t=t_0$

(204) Step B (**4542**): Store sensor data S1 and S2 at $t=t_0$

(205) Step C (**4544**): Increment time by time-step t_s : $t=t+t_s$

(206) Step D (**4546**): Store sensor data S1 and S2 at new time t

(207) Step E (**4548**): Calculate differential sensor data by subtracting sensor data S1 and S2 of previous time-step from sensor data S1 and S2 of current time-step, eliminating images of static objects.

(208) Step F (**4550**): Perform Algorithm 43A with differential sensor data as inputs S1 and S2

(209) Step G: Go back to Step C (4544) and continue until desired.

(210) FIG. 19A illustrates another embodiment of the invention where a system similar to imaging system 4210 in FIG. 15A may be achieved with the use of a beam-splitter to split the image between the two image sensors. The imaging system 4610 may include a lens 4612 with focal length f and aperture of size R , a beam-splitter 4618 whose center is of distance z_b from lens 4612 on its image side, a perpendicular image sensor 4613 (perpendicular in relation to the lens 4612) set at distance z_2^* from the center of the beam-splitter 4618, and whose effective distance from the lens, $z_2 = z_b + z_2^*$, corresponds to the image focal plane of another plane 4617 at distance d_2 from the lens 4612 on its real side, a parallel image sensor 4614 (parallel in relation to the lens 4612) set at distance z_1 from the lens 4612 on its image side which corresponds to the image focal plane of another plane 4616 at distance d_1 from the lens 4612 on its real side. The real workspace on the real side of the lens 4612 may be bounded by plane 4616 and plane 4617 at distances d_1 and d_2 respectively from the lens 4612. The images may be processed and stored by an integrated image processor and memory system 4606 connected to the image sensor arrays perpendicular image sensor 4613 and parallel image sensor 4614.

(211) Pixel alignment of the perpendicular image sensor 4613 and parallel image sensor 4614 may be achieved using the method described by FIG. 13C. Image reconstruction algorithms described in FIG. 14-18 are applicable to the imaging system described in FIG. 19A.

(212) FIG. 19B illustrates another embodiment of this invention where a system similar to imaging system 4210 in FIG. 15A may be achieved with the use of a single image sensor that may be actuated back-and-forth from the lens by a fast motor. The single image sensor imaging system 4650 may include a lens 4652 with focal length f and aperture of size R , an image sensor 4653 parallel in relation to the lens 4652 set on rails 4660 on the image side of the lens 4652, and an actuation motor 4654 that drives the lens along the rails 4660 with respect to the lens 4652.

(213) The image sensor 4653 may be actuated between two positions of distances z_1 and z_2 from the lens 4652. z_1 is the location of image focal plane 4659 which corresponds to another plane 4656 at distance d_1 from the lens 4652 on its real side, while z_2 is the location of image focal plane 4658 which corresponds to another plane 4657 at distance d_2 from the lens 4652 on its real side. The real workspace on the real side of the lens 4652 is bounded by plane 4656 and plane 4657 at distances d_1 and d_2 respectively from the lens 4652. The image sensor 4653 stores images of scenes within the real workspace when it is at locations z_1 and z_2 from the lens 4652. In this manner, it is behaving like two independent image sensors located at distances z_1 and z_2 from the lens 4652, similar to the imaging system 4110, and may have the advantage of not attenuating any of the light coming from the scene. The actuation motor 4654 may be a type of piezoelectric drive which typically has maximum linear speeds of 800,000 microns per second and precision of a few nanometers. For example, with a real workspace defined by the space from 1 to 10 meters from the lens of typical focal length about 5 mm, the distance between z_1 and z_2 with air in between will be about 22.5 microns, which allows the image sensor 4653 to move back and forth between the positions z_1 and z_2 at a rate of more than 15,000 times per second. Typically, this will be enough for a camera system to collect the two images where the frame rate is about 30 frames per second, even accounting for shutter speed and shutter delay. The collected images from image sensor array 4653 may be processed and stored by an integrated image processor and memory system 4151 connected to the image sensor array 4653.

(214) Pixel alignment of the image sensor 4653 along the rails 4660 specifically at positions z_1 and z_2 may be achieved using the method described by FIG. 13C where in this case the location of the photo-detector that detects the laser beam is inspected at positions z_1 and z_2 , and adjustments are made in the event of discrepancies. Image reconstruction algorithms described in FIG. 14-18 are applicable to the imaging system described in FIG. 19A.

(215) Several material systems have been illustrated as examples for various embodiments of this invention in this patent application. It will be clear to one skilled in the art based on the present disclosure that various other material systems and configurations can also be used without violating the concepts described. It will also be appreciated by persons of ordinary skill in the art that the present invention is not limited to what has been particularly shown and described hereinabove. Rather, the scope of the invention includes both combinations and sub-combinations of the various features described herein above as well as modifications and variations which would occur to such skilled persons upon reading the foregoing description. Thus the invention is to be limited only by the appended claims.

Claims

1. An integrated device, the device comprising: a first level comprising a first mono-crystal layer, said first mono-crystal layer comprising a plurality of single crystal transistors; an overlying oxide disposed on top of said first level; a second level comprising a second mono-crystal layer, said second level overlaying said oxide, wherein said second mono-crystal layer comprises a plurality of image sensors, wherein said second level is bonded to said first level comprising an oxide to oxide bond; a plurality of pixel control circuits; a third level disposed underneath said first level, wherein said third level comprises a plurality of third transistors, wherein said plurality of third transistors each comprise a single crystal channel; and a plurality of recessed channel transistors.
 2. The integrated device according to claim 1, wherein a thickness of said second mono-crystal layer is less than 5 microns.
 3. The integrated device according to claim 1, wherein said third level comprises a plurality of landing pads.
 4. The integrated device according to claim 1, wherein said first mono-crystal layer comprises alignment marks, and wherein said second level is aligned to said alignment marks.
 5. The integrated device according to claim 1, further comprising: a plurality of memory circuits.
 6. The integrated device according to claim 1, further comprising: at least three isolated single crystal layers.
 7. The integrated device according to claim 1, wherein each of said plurality of image sensors is directly connected to at least one of said plurality of pixel control circuits.
 8. An integrated device, the device comprising: a first level comprising a first mono-crystal layer, said first mono-crystal layer comprising a plurality of single crystal transistors; an overlying oxide disposed on top of said first level; a second level comprising a second mono-crystal layer, said second level overlaying said oxide, wherein said second mono-crystal layer comprises a plurality of image sensors, wherein said second level is bonded to said first level comprising an oxide to oxide bond; a plurality of pixel control circuits; a third level disposed underneath said first level, wherein said third level comprises a plurality of third transistors, wherein said plurality of third transistors each comprise a single crystal channel; and a plurality of metal gate transistors.
 9. The integrated device according to claim 8, wherein a thickness of said second mono-crystal layer is less than 5 microns.
 10. The integrated device according to claim 8, wherein said third level comprises a plurality of landing pads.
 11. The integrated device according to claim 8, wherein said first mono-crystal layer comprises alignment marks, and wherein said second level is aligned to said alignment marks.
 12. The integrated device according to claim 8, further comprising: a plurality of memory circuits.
 13. The integrated device according to claim 8, further comprising: at least three electrically isolated single crystal layers.
 14. The integrated device according to claim 8, wherein each of said plurality of image sensors is directly connected to at least one of said plurality of pixel control circuits.
 15. An integrated device, the device comprising: a first level comprising a first mono-crystal layer, said first mono-crystal layer comprising a plurality of single crystal transistors; an overlying oxide disposed on top of said first level; a second level comprising a second mono-crystal layer, said second level overlaying said oxide, wherein said second mono-crystal layer comprises a plurality of image sensors, wherein said second level is bonded to said first level comprising an oxide to oxide bond; a plurality of pixel control circuits; a third level disposed underneath said first level, wherein said third level comprises a plurality of third transistors, wherein said plurality of third transistors each comprise a single crystal channel, and wherein said plurality of image sensors is aligned to said plurality of single crystal transistors with a less than 600 nm alignment error; and a plurality of recessed channel transistors.
 16. The integrated device according to claim 15, wherein a thickness of said second mono-crystal layer is less than 5 microns.
 17. The integrated device according to claim 15, wherein said third level comprises a plurality of landing pads.
 18. The integrated device according to claim 15, wherein said first mono-crystal layer comprises alignment marks, and wherein said second level is aligned to said alignment marks.
 19. The integrated device according to claim 15, further comprising: a plurality of memory circuits.
 20. The integrated device according to claim 1, further comprising: at least three electrically isolated single crystal layers.
