Enlarging active areas of displays in electronic devices

Abstract

This document describes systems and techniques directed at enlarging active areas of displays in electronic devices. In aspects, a display includes a grid of transistors positioned within a display panel module to control an illumination of one or more electroluminescent layers. Routing lines extend from one or more transistors of the grid of transistors to at least one electroluminescent layer. In this way, the at least one electroluminescent layer can be positioned away from the grid of transistors and disposed above portions of display panel module driving circuitry. As a result, active areas of displays can be enlarged and information content can be maximized without a panel border area allotted to the display panel module driving circuitry surrounding transistors having to be reduced.

Inventors: Liu; Chun-Yen (Zhubei, TW), Chu; Chiaching (New Taipei, TW), Bitá; Ion (Los Altos, CA)

Applicant: Google LLC (Mountain View, CA)

Family ID: 1000008765364

Assignee: Google LLC (Mountain View, CA)

Appl. No.: 18/426046

Filed: January 29, 2024

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS (1) This application claims priority to U.S. Provisional Application Ser. No. 63/486,593, filed Feb. 23, 2023, the disclosure of which is incorporated herein by reference in its entirety.

BACKGROUND

(1) Wearable electronic devices, such as virtual-reality goggles and smartwatches, are increasing in popularity. These wearable devices are able to synchronize and communicate wireless data with other devices, including non-wearable devices like smartphones and laptops. Such wireless interconnectivity promotes user connectivity, productivity, and efficiency. In one example, upon receipt of an email notification, a laptop can wirelessly transmit the email notification to a smartwatch for viewing on its respective display. This technique and others like it afforded by wearable devices

provide many conveniences and are therefore highly valued by users.

SUMMARY

(2) This document describes systems and techniques directed at enlarging active areas of displays in electronic devices. In aspects, a display includes a grid of transistors positioned within a display panel module to control an illumination of one or more electroluminescent layers. Routing lines extend from one or more transistors of the grid of transistors to at least one electroluminescent layer. In this way, the at least one electroluminescent layer can be positioned away from the grid of transistors and disposed above portions of display panel module driving circuitry. As a result, active areas of displays can be enlarged and information content can be maximized without a panel border area allotted to the display panel module driving circuitry surrounding transistors having to be reduced.

(3) In aspects, a display is disclosed that includes an electroluminescent layer that is configured to emit light when a voltage is applied across a cathode and an anode. The display further includes a transistor configured to control an electrical activation of the electroluminescent layer by controlling the voltage across the cathode and the anode. The display also includes driving circuitry operatively coupled to the transistor and configured to control the transistor. Further, the display includes a routing line connected to an electrode of the transistor. Additionally, the display includes a routing metal operatively coupling the anode of the electroluminescent layer to the routing line. The routing metal extends from the routing line above at least portions of the driving circuitry. The electroluminescent layer is disposed above the at least portions of the driving circuitry via the operative coupling to the routing metal.

(4) This Summary is provided to introduce simplified concepts of systems and techniques directed at enlarging active areas of displays in electronic devices, the concepts of which are further described below in the Detailed Description and Drawings. This Summary is not intended to identify essential features of the claimed subject matter, nor is it intended for use in determining the scope of the claimed subject matter.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

(1) The details of one or more aspects of systems and techniques directed at enlarging active areas of displays in electronic devices are described in this document with reference to the following drawings:

(2) FIG. 1 illustrates an example implementation of an example display panel module with a display bezel and driving circuitry;

(3) FIG. 2 illustrates an example implementation of an example display panel module in which an enlarged emitting area can be implemented in accordance with one or more implementations;

(4) FIG. 3 illustrates an example device diagram of example electronic devices in which enlarged active areas can be implemented;

(5) FIG. 4 illustrates an example implementation of a smartwatch and an exploded view of an example display having a display panel module, a display cover layer, and integrated circuits;

(6) FIGS. 5A and 5B illustrate a first example implementation of a first display panel module and a second example implementation of a second display panel module, respectively;

(7) FIG. 6 illustrates an example implementation of a smartwatch and an exploded view of an example display with diodes overlaying portions of driving circuitry in accordance with one or more implementations;

(8) FIG. 7 illustrates the second example implementation of the second display panel module with more detail in accordance with one or more implementations;

(9) FIG. 8 illustrates a partial, cross-sectional view of an example display panel module;

(10) FIG. 9 illustrates a partial, cross-sectional view of an example display panel module that is configured with an enlarged active area in accordance with one or more implementations; and

(11) FIG. 10 illustrates a partial, cross-sectional view of another example display panel module that is configured with an enlarged active area in accordance with one or more implementations.

(12) The same numbers are used throughout the Drawings to reference like features and components.

DETAILED DESCRIPTION

Overview

(13) Many electronic devices include displays, such as light-emitting diode (LED) displays and liquid crystal displays (LCDs). These displays often include a pixel array having tens of thousands of pixels organized into a two-dimensional grid (e.g., circular grid, rectangular grid). To power and control the pixel array, displays may include driving circuitry, surrounding the perimeter of the pixel array, connecting the pixels to one or more drivers. As an example, a pixel array having a two-dimensional rectangular grid of pixels can be operably coupled to one or more row-line drivers via electrical traces (e.g., routing lines, wires) positioned around the rectangular grid.

(14) Electronic device manufactures generally fabricate these displays in a layered structure, often referred to as a “display panel stack.” The display panel stack includes a cover layer (e.g., cover glass) and a display panel module (e.g., pixel array, driving circuitry). Before a cover layer is bonded to the top of a display panel stack, an opaque border, often referred to as an “ink mask,” may be added to the underside of the cover layer, defining a display bezel. An amount of space consumed by the driving circuitry (e.g., electrical traces, drivers) often dictates a size of the display bezel. The amount of space consumed by the driving circuitry can vary depending on a specific application of the electronic device and/or a form factor of the display panel stack. Frequently, the display bezel is enlarged for display panel stacks having noncollinear regions. For instance, a display bezel may be larger for an electronic device with a display panel stack that is elliptically shaped. In another example, an electronic device with a rectangular display panel stack includes corner regions with a larger display bezel.

(15) The display bezel may serve as a frame, surrounding an active area of a display (e.g., an emissive area of a display panel module visible to a user) and hiding driving circuitry in an inactive area (e.g., non-emissive area) of a display. FIG. 1 illustrates an example implementation **100** of an example display panel module with a display bezel and driving circuitry. As illustrated, a display panel module **102** includes an active area **104** having one or more pixels circuits **106** (e.g., a first pixel circuit **106-1**, a second pixel circuit **106-2**, a third pixel circuit **106-3**, a fourth pixel circuit **106-4**) surrounded by an opaque border **108** (e.g., display bezel). The opaque border **108** may be positioned over and visibly conceal driving circuitry **110** within a panel border area **112**. In some implementations, an amount of space consumed by the driving circuitry **110** influences (e.g., dictates) a size of the opaque border **108** and/or the panel border area **112**. For example, to provide enough space for the driving circuitry **110**, the panel border area **112** may be 1-2 millimeters in width.

(16) Users of electronic devices often desire compact, aesthetic electronic devices with large display active areas. However, many electronic devices include displays with large display bezels, which may reduce a display active area and minimize information content. Displays of electronic devices with a circular form factor that are also configured to be wearable on a body of a user (e.g., smartwatches) are especially prone to having displays with large display bezels.

(17) To this end, this document describes systems and techniques directed at enlarging active areas of displays in electronic devices. In aspects, a display includes a grid of transistors positioned within a display panel module to control an illumination of one or more electroluminescent layers. Routing lines extend from one or more transistors of the grid of transistors to at least one electroluminescent layer. In this way, the at least one electroluminescent layer can be positioned away from the grid of transistors and disposed above portions of display panel module driving circuitry. As a result, active areas of displays can be enlarged and information content can be maximized without a panel border area allotted to the display panel module driving circuitry surrounding transistors having to be reduced.

(18) FIG. 2 illustrates an example implementation **200** of an example display panel module in which an enlarged emitting area can be implemented in accordance with one or more implementations. As illustrated, a display panel module **202** includes an enlarged active area **204** having one or more diodes **206** (e.g., a first diode **206-1**, a second diode **206-2**, a third diode **206-3**) positioned over

portions of driving circuitry (e.g., in a panel border area). For example, routing lines can extend from transistors **208** (e.g., a first transistor **208-1**, a second transistor **208-2**, a third transistor **208-3**) within a grid of transistors to diodes **206** positioned above driving circuitry (e.g., at a higher Z-coordinate, closer to a cover layer). Through such a technique, diodes **206** can be disposed outward (e.g., radially outward) on an X-Y plane from the grid of transistors. As a result, an area allotted to driving circuitry surrounding the transistors **208** does not have to be reduced in order to achieve the enlarged active area **204**. Instead, diodes **206** can be disposed above (e.g., at a higher Z-coordinate, underneath a cover layer but over the driving circuitry) the driving circuitry via electrical connection through routing lines to the transistors **208**.

(19) Although systems and techniques are described herein as being particularly relevant to smartwatches and elliptical displays, it is to be appreciated that the systems and techniques are also applicable to other electronic devices with irregular- or regular-shaped displays.

Example Environment

(20) FIG. 3 illustrates an example device diagram **300** of example electronic devices in which enlarged active areas can be implemented. The electronic devices may include additional components and interfaces omitted from FIG. 3 for the sake of clarity.

(21) An electronic device **302** can be any of a variety of consumer electronic devices. As non-limiting examples, the electronic device **302** can be a mobile phone **302-1**, a tablet device **302-2**, a laptop computer **302-3**, a portable video game console **302-4**, virtual-reality (VR) goggles **302-5**, a smartwatch **302-6** (e.g., a computerized watch), and the like.

(22) The electronic device **302** includes one or more processors **304**. The processor(s) **304** can include, as non-limiting examples, a system on a chip (SoC), an application processor (AP), a central processing unit (CPU), or a graphics processing unit (GPU). The processor(s) **304** generally execute commands and processes utilized by the electronic device **302** and an operating system installed thereon. For example, the processor(s) **304** may perform operations to display graphics of the electronic device **302** on a display **314** and can perform other specific computational tasks.

(23) The electronic device **302** also includes computer-readable storage media (CRM) **306**. The CRM **306** may be a suitable storage device configured to store device data of the electronic device **302**, user data, and multimedia data. The CRM **306** may store an operating system that generally manages hardware and software resources (e.g., applications) of the electronic device **302** and provides common services for applications stored on the CRM. The operating system and the applications are generally executable by the processor(s) **304** to enable communications and user interaction with the electronic device **302**. One or more processor(s) **304**, such as a GPU, perform operations to display graphics of the electronic device **302** on the display **314** and can perform other specific computational tasks. The processor(s) **304** can be single-core or multiple-core processors.

(24) The electronic device **302** may also include input/output (I/O) ports **310**. The I/O ports **310** allow the electronic device **302** to interact with other devices or users. The I/O ports **310** may include any combination of internal or external ports, such as universal serial bus (USB) ports, audio ports, Serial ATA (SATA) ports, PCI-express based ports or card-slots, secure digital input/output (SDIO) slots, and/or other legacy ports.

(25) The electronic device **302** further includes one or more sensors **312**. The sensor(s) **312** can include any of a variety of sensors, such as an audio sensor (e.g., a microphone), a touch-input sensor (e.g., a touchscreen), an image-capture device (e.g., a camera, video-camera), proximity sensors (e.g., capacitive sensors), or an ambient light sensor (e.g., photodetector). In implementations, the electronic device **302** includes one or more of a front-facing sensor(s) and a rear-facing sensor(s).

(26) Further, the electronic device **302** includes the display **314** (e.g., a display panel stack) having a display panel module **316** and a cover layer **318**. The display **314** may further include, integrated within the display panel module **316** or altogether separate from the display panel module **316**, one or more of a touch layer (e.g., touch sensor panel) and a polarizer layer (e.g., polarization filters). In implementations, the display panel module **316** includes a two-dimensional pixel array operably coupled to one or more row-line or column-line drivers via electrical traces.

(27) Pixels of the pixel array may be implemented as pixel circuits. The design of the pixel circuits may vary depending on the type of display technology implemented within the electronic device **302**. For example, in organic light-emitting diode (OLED) displays, each pixel circuit can include a transistor (e.g., a thin-film transistor (TFT)) and one or more diodes (e.g., sub-pixels, electroluminescent layers) that emit red, green, blue, and/or infrared light. Although systems and techniques are described herein as being particularly relevant to OLED displays, it is to be appreciated that the systems and techniques may be used in conjunction with or applicable to other display technologies. Further, an electroluminescent layer may be considered to include any form of a layer or a region that is caused to emit light in response to a flow of an electric current through the layer or the region, or the application of an electric field across the layer or the region. An array formed of a plurality of electroluminescent layers may comprise an array of organic light-emitting diodes. Each of the plurality of electroluminescent layers may be associated with a corresponding transistor of a plurality of transistors. The plurality of transistors may be arranged in a grid or an array.

(28) In aspects, the pixel array generates light to create an image on the display **314** upon electrical activation by one or more drivers. As an example, data-line drivers provide voltage data via electrical traces to pixel circuits of the pixel array to control a luminance of diodes. In at least some instances, sections of the display panel module **316** (e.g., a bottom section, a rounded corner) may include more driving circuitry and/or a larger panel border area than other portions of the display panel module **316** (e.g., a top section, a collinear side section).

(29) FIG. **4** illustrates an example implementation **400** of a smartwatch **302-6** and an exploded view of an example display **314** having a display panel module **316**, a display cover layer **318**, and integrated circuits **404**. The display cover layer **318** may be composed of any of a variety of translucent materials including polymer (e.g., plastic, acrylic), glass, and so forth and may form any three-dimensional shape (e.g., a polyhedron), such as a rectangular prism or cylinder. During manufacturing of the display **314**, an opaque border **402** may be added (e.g., laminated, printed) to a bottom face (e.g., underside) of the cover layer **318**. As an example, the opaque border **402** is a black ink mask adhered to the bottom face of the cover layer **318**. The opaque border **402** may have an inner diameter and an outer diameter. The difference between the inner diameter and the outer diameter may define a thickness of the opaque border **402**. The bottom face of the cover layer **318** may then be bonded to the display panel module **316**, forming a display panel stack. In some implementations, a width and/or a length of the display panel module **316**, when packaged in an electronic device **302**, is less than or equal to a width and/or a length, respectively, of the cover layer **318**. In alternative implementations, a width and/or a length of the display panel module **316**, when packaged in an electronic device **302**, is greater than a width and/or a length, respectively, of the cover layer **318**. For example, portions of the display panel module **316**, including driving circuitry, may extend beyond the cover layer **318** but may be hidden by a housing of an electronic device **302**.

(30) As further illustrated, an enlarged active area **408** includes pixel circuits **410** (e.g., pixel circuit **410-1**, pixel circuit **410-2**, pixel circuit **410-3**, pixel circuit **410-4**). Each pixel circuit **410** may include one or more transistors **412**. For example, pixel circuit **410-1** may include a first transistor **412-1**, a second transistor **412-2**, and a third transistor **412-3** to control one or more diodes (not illustrated).

(31) In implementations, the opaque border **402** hides at least portions of driving circuitry in a panel border area **406** of the display panel module **316** and frames the enlarged active area **408**. In this way, at least portions of the driving circuitry can be hidden from a user's perception while viewing the display **314**. As an example only and not by way of limitation, the driving circuitry includes, as illustrated in FIG. **4**, a compensation capacitor **414**, a high-level power supply voltage source ("ELVDD") **416** (e.g., OLED display positive power supply), a demultiplexer circuit **418**, a gate driver on array **420** (GOA **420**), source lines **422** (e.g., source drivers), and a low-level power supply voltage source ("ELVSS") **424** (e.g., OLED display negative power supply). The panel border area **406** may further include a dam portion **426** (e.g., a patterned insulator film surrounding a periphery of an active area) and a crack dam **428** (e.g., a crack-prevention dam).

(32) The compensation capacitor **414** may be configured to maintain a constant voltage across one or

more diodes (e.g., one or more electroluminescent layers). The demultiplexer circuit **418** (e.g., a one to six (1:6) demultiplexer) may be configured to take one or more input signals and route them to one of several output lines based on a state of control inputs. The GOA **420** may include gate lines that run horizontally (e.g., parallel to the row direction) along the width of the display **314**. The gate lines may connect to rows of pixel circuits **410** and send signals that activate the transistors **412**. In implementations, the transistors **412** can control current flow, enabling or disabling current to flow through the one or more diodes. The source lines **422** may run vertically (e.g., perpendicular to a row direction) along the length of the display **314** from one or more display drivers and connect to the demultiplexer circuit **418**. The dam portion **426** and the crack dam **428** may include a patterned insulator film configured to prevent crack propagation and external forces from peeling off an encapsulation film.

(33) It will be appreciated by one skilled in the art that FIG. **4** is provided as an example only, for the techniques described herein are also applicable to electronic devices that include additional or fewer driving circuit components than those illustrated in FIG. **4**. Moreover, an arrangement of driving circuit components in electronic devices may differ than those illustrated in FIG. **4** and still utilize the techniques described herein.

(34) FIGS. **5A** and **5B** illustrate a first example implementation **500-1** of a first display panel module **502-1** and a second example implementation **500-2** of a second display panel module **502-2**, respectively. As illustrated in FIG. **5A**, the first display panel module **502-1** has an active area **504** (e.g., active area **104**) that includes a plurality of diodes **506-1** (e.g., red, green, blue (RGB) diodes) operatively coupled to transistors **508-1**. Further illustrated, a width of a panel border area **510-1** of the display panel module **502-1** may be larger than a width of a driving circuitry **512-1**. As an example, the panel border area **510-1** can range from 1.2 to 1.6 millimeters. In alternative implementations (not illustrated), the width of the panel border area **510-1** of the display panel module **502-1** may be equal to the width of the driving circuitry **512-1**.

(35) FIG. **5B**, on the other hand, illustrates the second display panel module **502-2** having the enlarged active area **408**, which is larger than the active area **504** of the first display panel module **502-1**. The second display panel module **502-2** can include the enlarged active area **408** by overlaying one or more diodes (e.g., electroluminescent layers) of a plurality of diodes **506-2** over at least portions of driving circuitry **512-2**. In this way, at least portions of the driving circuitry **512-2** can be hidden by the one or more diodes, resulting in a reduced panel border area **510-2** that can be hidden by a thinner opaque border (e.g., opaque border **402**). As a result, a user can visually perceive an enlarged viewing area (e.g., the active area **408**) with a narrower opaque border. Through such a technique, a panel border area (e.g., panel border area **510-1**) can be reduced by 0.2 to 1.0 millimeters, for example. A thickness of the opaque border, which may be defined as the difference between the inner diameter and the outer diameter of the opaque border, may be selected such that it hides one or more components driving circuitry **512-2** (e.g., components of the driving circuitry **512-2** over which an extended emitting area does not extend). For example, the thickness of the opaque border can be based on a placement of an electroluminescent layer above portions of the driving circuitry **512-2**, since such placement allows the electroluminescent layers to hide the driving circuitry **512-2**.

(36) In at least some implementations, a pixel per inch (PPI) (e.g., a number of pixels in a display per one inch of its diagonal length, a measure of resolution, a density of pixels) of the display panel module **502-2** may be uniform across the entire enlarged active area **408**. In other implementations, an inner region of the enlarged active area **408** may possess a first uniform PPI, while an outer region (e.g., where diodes have been extended outward) of the enlarged active area **408** may possess a second uniform PPI. The first uniform PPI may be greater than the second uniform PPI. A difference between the first uniform PPI and the second uniform PPI may be visually imperceptible to a user. In still further implementations, a density of transistors (e.g., transistors **508-2**) within the enlarged active area **408** may be greater than a density of pixels (e.g., a red, green blue (RGB) pixel) and/or diodes **506-2**.

(37) FIG. **6** illustrates an example implementation **600** of a smartwatch **302-6** and an exploded view

of an example display **314** with diodes **602** overlaying portions of driving circuitry (e.g., driving circuitry **512-2**) in accordance with one or more implementations. As illustrated, the enlarged active area **408** is enlarged (e.g., in comparison to active area **504**) by positioning diodes **602** over portions of driving circuitry (see FIG. 4 and/or FIG. 5B). For example, routing lines **604** (e.g., routing line **604-1**, routing line **604-2**, routing line **604-3**) can extend from transistors **412** (e.g., transistor **412-1**, transistor **412-2**, transistor **412-3**) to diodes **602** (e.g., diode **602-1**, diode **602-2**, diode **602-3**) positioned above driving circuitry (e.g., at a higher Z-coordinate, closer to a cover layer), enabling the diodes **602** to be disposed radially outward on an X-Y plane from the transistors **412**. As a result, an area allotted to driving circuitry surrounding the transistors **412** does not have to be reduced in order to enlarge an active area. Instead, diodes **602** can be disposed above the driving circuitry via electrical connection through the routing lines **604** to the transistors **412**.

(38) In implementations, the routing lines **604** (e.g., metal interconnects) can be composed of any of a variety of materials, including titanium, aluminum, copper, or a combination thereof. Further, the routing lines **604** may extend (e.g., vertically, horizontally) tens and/or hundreds of micrometers or millimeters from a respective transistor (e.g., transistor **412-2**) to a respective diode (e.g., diode **602-2**). The routing lines **604** may be configured to route electrical signals and/or power to the diodes **602**. The diodes **602** (e.g., sub-pixels, electroluminescent layers) can, individually or collectively, emit light of varying wavelengths (e.g., visible light, infrared light). In one example, the diode **602-1** is a diode configured to emit blue light.

(39) FIG. 7 illustrates the second example implementation **500-2** of the second display panel module **502-2** with more detail in accordance with one or more implementations. FIG. 7 is described in the context of FIGS. 3, 4, 5B, and 6. As illustrated, the second display panel module **502-2** includes the enlarged active area **408**, the plurality of diodes **506-2**, the transistors **508-2**, and the driving circuitry **512-2**. The second display panel module **502-2** can include the enlarged active area **408** by overlaying one or more diodes (e.g., electroluminescent layers) of the plurality of diodes **506-2** over at least portions of the driving circuitry **512-2**.

(40) As illustrated, the plurality of diodes **506-2** may be divided between an inner region **700** and an outer region **702**. The inner region **700** may include a first set of diodes of the plurality of diodes **506-2**, while the outer region **702** may include a second set of diodes of the plurality of diodes **506-2**. In implementations, as illustrated in FIG. 7, the second set of diodes includes at least one diode that is positioned away from a grid of transistors **704** in at least one dimension of an X-Y plane (e.g., an X-axis, a Z-axis). In additional implementations, the outer region **702** may be defined from a border of the inner region **700** to a border of the enlarged active area **408**. The outer region **702** may extend along an entire outer perimeter of the enlarged active area **408**. As described herein, the term grid is to be understood as describing a two- or three-dimensional network of elements, such as transistors, arranged in one or more patterns.

(41) The grid of transistors **704** may form any of a variety of regular (e.g., rectangular, elliptical) or irregular shapes. In implementations, the grid of transistors **704** is dimensionally smaller (e.g., with respect to the X-Y plane) than the enlarged active area **408** (e.g., pixel array, the inner region **700** and the outer region **702**). In further implementations, as illustrated in FIG. 7, the grid of transistors **704** may be concentric with the enlarged active area **408**. In alternative implementations, the grid of transistors **704** and the enlarged active area **408** may each have a geometric center (e.g., an origin), which are offset any number of micrometers or millimeters in an X-Y plane. The grid of transistors **704** may have a uniform distribution of transistors.

(42) Further illustrated, the first set of diodes of the plurality of diodes **506-2** may include a first density of diodes. The first density of diodes may be uniform over an entirety of the inner region **700**. The second set of diodes of the plurality of diodes **506-2** may include a second density of diodes. In at least some implementations, the second density of diodes is uniform over an entirety of the outer region **702**. The first density of diodes may be greater than the second density of diodes. In alternative implementations, the second density of diodes is non-uniform over an entirety of the outer region **702**. In still further implementations, one or more diodes in the second set of diodes may be dimensionally

larger than diodes in the first set of diodes, and/or diodes in the second set of diodes may be arranged in a different pattern than diodes in the inner region **700**.

(43) FIG. **8** illustrates a partial, cross-sectional view **800** of an example display panel module (e.g., display panel module **102**). FIG. **8** is described in the context of FIGS. **1** and **5A**. As illustrated, the display panel module includes an electroluminescent layer **802** (e.g., diode **602-1**). In implementations, the electroluminescent layer **802** is composed of organic materials that emit light of varying wavelengths and/or intensities depending on an amount of electrical current passed through it (e.g., electroluminescence).

(44) As illustrated, the electroluminescent layer **802** is positioned between a cathode **804** and an anode **806**. The electroluminescent layer **802** may emit light when a voltage is applied across the cathode **804** and the anode **806**. Disposed above the cathode **804** is a thin-film encapsulation (TFE) layer **808** (e.g., a metal encapsulation). The TFE layer **808** is a transparent material configured to protect the display panel module from ingress contaminants, such as dust and moisture. Disposed below the electroluminescent layer **802**, adjacent to the cathode **804** and the anode **806**, is a pixel define layer **810** (PDL **810**). Beneath the PDL **810**, a planarization layer **812** (“PLN2” **812**) may be disposed. Both PDL **810** and PLN2 **812** may be composed of electrically insulating materials.

(45) Further illustrated, a routing line **814** is operatively coupled (e.g., electrically connected) to the anode **806** and an electrode of a transistor **816** (e.g., a coplanar oxide thin-film transistor). In one example, the routing line **814** is operatively coupled to the anode **806** and a drain electrode of a low-temperature polycrystalline silicon (LTPS) p-type thin-film transistor **816**. Further, the display panel module includes another planarization layer **818** (“PLN1” **818**), an inter-layer dielectric (ILD) layer **820**, a first gate insulator (GI) layer **822**, and a second GI layer **824**. The ILD layer **820** may be composed of an organic- or inorganic-insulating material configured to separate and isolate sub-pixel drive components. The GI layers (e.g., GI layer **822**, GI layer **824**) may be implemented as thin layers of, for example, silicon dioxide or silicon nitride. The GI layers may be configured to provide a barrier between a gate electrode and organic materials in the display panel module, preventing metals from reacting with organic materials. Further, the GI layers may assist in managing (e.g., controlling) a flow of current through the display panel module.

(46) In addition, the display panel module includes a buffer layer **826** and a polyimide (“PI”) substrate **828**. The buffer layer **826** can be configured to reduce electrical resistance, improve adhesion between layers, prevent chemical reactions between different layers, and/or protect the display panel module from ingress contaminants. The PI substrate **828** provides mechanical stability and serves as a flexible base for other layers. FIG. **8** also illustrates the division between an active area **830** (e.g., active area **104**) and driving circuitry **832** (e.g., driving circuitry **512-1**). Further, FIG. **8** illustrates a first gate line **834** patterned in the GI layer **822** and a second gate line **836** patterned in the ILD layer **820**.

(47) FIG. **9** illustrates a partial, cross-sectional view **900** of an example display panel module (e.g., display panel module **316**) that is configured with an enlarged active area (e.g., enlarged active area **408**) in accordance with one or more implementations. FIG. **9** is described in the context of FIGS. **3**, **4**, **5B**, **6**, and **7**. The display panel module includes one or more components of the display panel module from FIG. **8**. Common parts are shown with like reference numerals and may not be described again.

(48) As illustrated, the display panel module includes a third planarization layer **902** (“PLN3” **902**) and a routing metal **904**. In such a configuration, PLN2 **812** physically supports and electrically insulates the routing line **814** and the routing metal **904**, while PLN3 physically supports and electrically insulates the routing metal **904** and the anode **806**. In aspects, the routing metal **904** can extend from and operatively couple (e.g., electrically connect) the routing line **814** to the anode **806**. Through the addition of the routing metal **904**, the electroluminescent layer **802** can be positioned at an X, Y, and/or Z three-dimensional coordinate independent of an X, Y, and/or Z three-dimensional coordinate of the transistor **816**. For example, the electroluminescent layer **802** can be disposed a few micrometers or millimeters away from the transistor **816** in an X-Y plane. In this way, one or more electroluminescent layers **802** (e.g., diodes) can be overlaid above (e.g., at a higher Z location) at least

portions of the driving circuitry **832** (e.g., driving circuitry **512-2**), and an emitting area can be extended to produce an enlarged active area **906**.

(49) FIG. **10** illustrates a partial, cross-sectional view **1000** of another example display panel module (e.g., display panel module **316**) that is configured with an enlarged active area (e.g., enlarged active area **408**) in accordance with one or more implementations. FIG. **10** is described in the context of FIGS. **3**, **4**, **5B**, **6**, and **7**. The display panel module includes one or more components of the display panel module from FIG. **8** and/or FIG. **9**. Common parts are shown with like reference numerals and may not be described again.

(50) As illustrated, the display panel module includes a shielding conductor layer **1002**. In such a configuration, PLN2 **812** and PLN1 **818** physically support and electrically insulate the shielding conductor layer **1002**. The shielding conductor layer **1002** may be operatively coupled to a direct current (DC) reference voltage from a high-level power supply voltage source (e.g., ELVDD **416**), a low-level power supply voltage source (e.g., ELVSS **424**), or other electrodes. The shielding conductor layer **1002** can be composed of any of a variety of materials and can be disposed at any position below the anode **806** and/or routing metal **904**. Through the addition of the shielding conductor layer **1002**, the anode **806** may be shielded from parasitic coupling capacitances originating from the driving circuitry **832**. As a result, a voltage of the anode **806** (“anode voltage”) can be insulated from, for example, the demultiplexer circuit **418**, the GOA **420**, clock bus lines, and/or the source lines **422**. The shielding conductor layer **1002** can, therefore, mitigate anode voltage fluctuations resulting in undesirable display artifacts, including a line mura, a band mura, and display flickering.

(51) In at least some implementations, a routing pitch of the routing metal **904** may be held to less than five (5) micrometers. Further to the above descriptions, a size of a respective electroluminescent layer (e.g., electroluminescent layer **702**) may differ from a size of another electroluminescent layer within a single display panel module. For example, electroluminescent layers within an inner region (e.g., inner region **700**) may be smaller than electroluminescent layers within an outer region (e.g., outer region **702**) of an enlarged active area (e.g., enlarged active area **408**).

CONCLUSION

(52) Unless context dictates otherwise, use herein of the word “or” may be considered use of an “inclusive or,” or a term that permits inclusion or application of one or more items that are linked by the word “or” (e.g., a phrase “A or B” may be interpreted as permitting just “A,” as permitting just “B,” or as permitting both “A” and “B”). Also, as used herein, a phrase referring to “at least one of” a list of items refers to any combination of those items, including single members. For instance, “at least one of a, b, or c” can cover a, b, c, a-b, a-c, b-c, and a-b-c, as well as any combination with multiples of the same element (e.g., a-a, a-a-a, a-a-b, a-a-c, a-b-b, a-c-c, b-b, b-b-b, b-b-c, c-c, and c-c-c, or any other ordering of a, b, and c). Further, items represented in the accompanying Drawings and terms discussed herein may be indicative of one or more items or terms, and thus reference may be made interchangeably to single or plural forms of the items and terms in this written description.

(53) Terms such as “above” or “below” are not intended to require any particular orientation of a device. Rather, a first layer or component, being provided “above” a second layer or component is intended to describe the first layer being at a higher Z-dimension than the second layer of component within the particular coordinate system in use. It will be understood that should the component be provided in another orientation, or described in a different coordinate system, then such relative terms may be changed.

(54) Although implementations for enlarging active areas of displays in electronic devices have been described in language specific to certain features and/or methods, the subject of the appended Claims is not necessarily limited to the specific features or methods described. Rather, the specific features and methods are disclosed as example implementations for enlarging active areas of displays in electronic devices.

Claims

1. A display comprising: a cover layer positioned as a topmost layer; an electroluminescent layer positioned underneath the cover layer and configured to emit light when a voltage is applied across a cathode and an anode; a transistor configured to control an electrical activation of the electroluminescent layer by controlling the voltage across the cathode and the anode; driving circuitry positioned underneath the cover layer and operatively coupled to the transistor, the driving circuitry configured to control the transistor; a shielding conductor layer configured to shield the anode from parasitic coupling capacitances originating from the driving circuitry, the shielding conductor layer operatively coupled to a direct current reference voltage; a routing line connected to an electrode of the transistor; and a routing metal operatively coupling the anode of the electroluminescent layer to the routing line, the routing metal extending from the routing line above at least portions of the driving circuitry, and the electroluminescent layer disposed above the at least portions of the driving circuitry such that the electroluminescent layer is positioned between the cover layer and the driving circuitry.
2. The display of claim 1, wherein the driving circuitry comprises at least one of a compensation capacitor, a high-level power supply voltage source, a demultiplexer circuit, a gate driver on array, source lines, or a low-level power supply voltage source.
3. The display of claim 2, wherein: the driving circuitry comprises the demultiplexer circuit and the gate driver on array; and the routing metal and the electroluminescent layer are disposed above at least one of the demultiplexer circuit or the gate driver on array.
4. The display of claim 1, wherein the shielding conductor layer is disposed at least partially underneath the routing metal.
5. The display of claim 1, wherein: the electroluminescent layer is one of a plurality of electroluminescent layers, each electroluminescent layer of the plurality of electroluminescent layers having a respective cathode and a respective anode, and wherein the plurality of electroluminescent layers form an array; the transistor is one of a plurality of transistors, each transistor of the plurality of transistors being associated with a respective electroluminescent layer of the plurality of electroluminescent layers, and wherein the plurality of transistors form a grid; the routing line is one of a plurality of routing lines, each routing line of the plurality of routing lines being operatively coupled to a respective transistor of the plurality of transistors; and the routing metal is one of a plurality of routing metals, each routing metal of the plurality of routing metals operatively coupling the anode of a respective electroluminescent layer of the plurality of electroluminescent layers to a respective routing line of the plurality of routing lines.
6. The display of claim 5, wherein: the array of electroluminescent layers comprises a uniform density of electroluminescent layers; the grid of transistors comprises a uniform density of transistors; and the array of electroluminescent layers comprises a larger area than the grid of transistors.
7. The display of claim 5, wherein: the array of electroluminescent layers comprises an inner region and an outer region; the inner region comprises a first density of electroluminescent layers; and the outer region comprises a second density of electroluminescent layers.
8. The display of claim 7, wherein the first density of electroluminescent layers is greater than the second density of electroluminescent layers.
9. The display of claim 7, wherein one or more electroluminescent layers in the outer region are disposed above at least portions of the driving circuitry.
10. The display of claim 7, wherein the outer region extends along an entire outer perimeter of the array of electroluminescent layers.
11. The display of claim 1, wherein the display comprises an elliptical form factor.
12. The display of claim 1, wherein the electroluminescent layer comprises a red diode, a green diode, a blue diode, or an infrared diode.
13. The display of claim 1, wherein the display further comprises: an opaque border bonded to a

bottom face of the cover layer, the opaque border having an outer diameter and an inner diameter, and wherein a thickness between the inner diameter and the outer diameter is based on a placement of the electroluminescent layer above the at least portions of the driving circuitry.

14. A wearable device comprising: a housing; one or more processors disposed within the housing; and a display operably coupled to the one or more processors and at least partially disposed within the housing, the display comprising: a cover layer positioned as a topmost layer, the cover layer including an opaque border having an outer diameter and an inner diameter; an electroluminescent layer positioned underneath the cover layer and configured to emit light when a voltage is applied across a cathode and an anode; a transistor configured to control an electrical activation of the electroluminescent layer by controlling the voltage across the cathode and the anode; driving circuitry positioned underneath the cover layer and operatively coupled to the transistor, the driving circuitry configured to control the transistor; a routing line connected to an electrode of the transistor; and a routing metal operatively coupling the anode of the electroluminescent layer to the routing line, the routing metal extending from the routing line above at least portions of the driving circuitry, and the electroluminescent layer disposed above the at least portions of the driving circuitry such that the electroluminescent layer is positioned between the cover layer and the driving circuitry, and a thickness between the inner diameter and the outer diameter based on a placement of the electroluminescent layer above the at least portions of the driving circuitry.

15. The wearable device of claim 14, wherein: the electroluminescent layer is one of a plurality of electroluminescent layers, each electroluminescent layer of the plurality of electroluminescent layers having a respective cathode and a respective anode, and wherein the plurality of electroluminescent layers form an array; the transistor is one of a plurality of transistors, each transistor of the plurality of transistors being associated with a respective electroluminescent layer of the plurality of electroluminescent layers, and wherein the plurality of transistors form a grid; the routing line is one of a plurality of routing lines, each routing line of the plurality of routing lines being operatively coupled to a respective transistor of the plurality of transistors; and the routing metal is one of a plurality of routing metals, each routing metal of the plurality of routing metals operatively coupling the anode of a respective electroluminescent layer of the plurality of electroluminescent layers to a respective routing line of the plurality of routing lines.

16. The wearable device of claim 15, wherein: the array of electroluminescent layers comprises a uniform density of electroluminescent layers; the grid of transistors comprises a uniform density of transistors; and the array of electroluminescent layers comprises a larger area than the grid of transistors.

17. The wearable device of claim 15, wherein: the array of electroluminescent layers comprises an inner region and an outer region; the inner region comprises a first density of electroluminescent layers; and the outer region comprises a second density of electroluminescent layers.

18. The wearable device of claim 17, wherein at least one of: the first density of electroluminescent layers is greater than the second density of electroluminescent layers; or one or more electroluminescent layers in the outer region are disposed above at least portions of the driving circuitry.

19. The wearable device of claim 17, wherein the display comprises an elliptical form factor.

20. The wearable device of claim 14, wherein the display further comprises: a shielding conductor layer configured to shield the anode from parasitic coupling capacitances originating from the driving circuitry, the shielding conductor layer operatively coupled to a direct current reference voltage.

21. A display comprising: a cover layer positioned as a topmost layer, the cover layer including an opaque border having an outer diameter and an inner diameter; an electroluminescent layer positioned underneath the cover layer and configured to emit light when a voltage is applied across a cathode and an anode; a transistor configured to control an electrical activation of the electroluminescent layer by controlling the voltage across the cathode and the anode; driving circuitry positioned underneath the cover layer and operatively coupled to the transistor, the driving circuitry configured to control the transistor; a routing line connected to an electrode of the transistor; and a routing metal operatively

coupling the anode of the electroluminescent layer to the routing line, the routing metal extending from the routing line above at least portions of the driving circuitry, and the electroluminescent layer disposed above the at least portions of the driving circuitry such that the electroluminescent layer is positioned between the cover layer and the driving circuitry, and a thickness between the inner diameter and the outer diameter based on a placement of the electroluminescent layer above the at least portions of the driving circuitry.
