

US012390510B2

(12) **United States Patent**
Stankovic et al.

(10) **Patent No.:** **US 12,390,510 B2**
(45) **Date of Patent:** **Aug. 19, 2025**

(54) **METHODS OF TREATING SENSORINEURAL HEARING LOSS USING FIBROBLAST GROWTH FACTOR 2 (FGF2)**

(71) Applicant: **Massachusetts Eye and Ear Infirmary**, Boston, MA (US)

(72) Inventors: **Konstantina Stankovic**, Boston, MA (US); **Nadia A. Atai**, Boston, MA (US); **Brad Welling**, Boston, MA (US); **Richard Seist**, Cambridge, MA (US)

(73) Assignee: **Massachusetts Eye and Ear Infirmary**, Boston, MA (US)

(*) Notice: Subject to any disclaimer, the term of this patent is extended or adjusted under 35 U.S.C. 154(b) by 86 days.

(21) Appl. No.: **17/614,845**

(22) PCT Filed: **May 29, 2020**

(86) PCT No.: **PCT/US2020/035198**
§ 371 (c)(1),
(2) Date: **Nov. 29, 2021**

(87) PCT Pub. No.: **WO2020/243478**
PCT Pub. Date: **Dec. 3, 2020**

(65) **Prior Publication Data**
US 2022/0226437 A1 Jul. 21, 2022

Related U.S. Application Data

(60) Provisional application No. 62/854,287, filed on May 29, 2019.

(51) **Int. Cl.**

METHODS OF TREATING SENSORINEURAL HEARING LOSS USING FIBROBLAST GROWTH FACTOR 2 (FGF2)

CLAIM OF PRIORITY

This application is a national stage entry of PCT/US2020/035198, filed on May 29, 2020, which claims the benefit of U.S. Provisional Patent Application Ser. No. 62/854,287, filed on May 29, 2019. The entire contents of the foregoing are hereby incorporated by reference.

FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

This invention was made with Government support under Grant No. DC015824 awarded by the National Institutes of Health. The Government has certain rights in the invention.

SEQUENCE LISTING

This application contains a Sequence Listing that has been submitted electronically as an ASCII text file named "00633-0264US1SequenceListing.txt". The ASCII text file, created on Nov. 23, 2021, is 1,717 bytes in size. The material in the ASCII text file is hereby incorporated by reference in its entirety.

TECHNICAL FIELD

Described herein are methods of using Fibroblast growth factor 2 (FGF2) to treat subjects with hearing loss associated with impaired word recognition.

BACKGROUND

Hearing loss is a worldwide problem of striking magnitude with no FDA-approved drugs. Disabling hearing loss affects 466 million people across the globe and that number is expected to increase to 900 million by 2050¹. The annual cost of unaddressed hearing loss is \$750 billion globally¹ and over \$56 billion in the United States². Most of this burden is due to sensorineural hearing loss (SNHL). Despite these astounding statistics, pharmacological therapies for SNHL are virtually nonexistent.

SUMMARY

The present disclosure addresses a major bottleneck in the auditory field: the need for robust, expandable, and biologically diverse cellular models that recapitulate the defining features of human disease and could be used to evaluate new biological therapies in a high throughput fashion. Described herein is the first human cellular model of acoustic trauma and synaptopathy. The experiments shown herein focused on inducing loss of neurites and synapses in that model because that pathology is known to underlie SNHL with compromised word recognition—the type of SNHL that is most socially disabling and for which current therapies (e.g., hearing aids and cochlear implants) have limited efficacy.

Thus, provided herein are methods for treating a subject who has sensorineural hearing loss (SNHL) with compromised word recognition. The methods include identifying a subject who has SNHL with compromised word recognition; and administering to the subject a therapeutically effective amount of Fibroblast growth factor 2 (FGF2) to the inner

2

ear. Also provided is the use of FGF2 for treating a subject who has sensorineural hearing loss (SNHL) with compromised word recognition.

Also provided herein are methods for regenerating cochlear synapses in a subject. The methods include identifying a subject who has a loss of cochlear synapses; and administering to the subject a therapeutically effective amount of FGF2 to the inner ear. Also provided is the use of FGF2 for regenerating cochlear synapses in a subject who has a loss of cochlear synapses.

In some embodiments, the subject does not have tympanic membrane damage or rupture.

In some embodiments, the subject does not have tympanic membrane damage or rupture.

In some embodiments, the subject has sensorineural hearing loss (SNHL) with compromised word recognition, tinnitus or hyperacusis.

In some embodiments, the FGF2 is delivered via trans-tympanic delivery or intratympanic administration.

In some embodiments, the FGF2 is administered by implantation of a bioabsorbable matrix that releases FGF2 over time. In some embodiments, the bioabsorbable matrix comprises gelatin.

In some embodiments, the treatment results in an increase in wave I ABR, and the methods can optionally include measuring wave I ABR before and/or after treatment.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Methods and materials are described herein for use in the present invention; other, suitable methods and materials known in the art can also be used. The materials, methods, and examples are illustrative only and not intended to be limiting. All publications, patent applications, patents, sequences, database entries, and other references mentioned herein are incorporated by reference in their entirety. In case of conflict, the present specification, including definitions, will control.

Other features and advantages of the invention will be apparent from the following detailed description and figures, and from the claims.

DESCRIPTION OF DRAWINGS

The patent or application file contains at least one drawing executed in color. Copies of this patent or patent application publication with color drawing(s) will be provided by the Office upon request and payment of the necessary fee.

FIG. 1: Schematic of the hearing chain. A cochlear cross section depicts hair cells (blue), spiral ganglion neurons (yellow), and other cochlear cell types (gray). Brain scan on the right indicates auditory nuclei in the brain stem, mid-brain and thalamus (yellow circles), as well as the primary auditory cortex (yellow ovals). Figure adapted in part from FIG. 1 of Mercier et al., Nat Biotechnol. 2012 December; 30(12): 1240-1243.

FIGS. 2A-C: Rapid generation, characterization and oxidative stressing of human induced pluripotent stem cell (iPSC)-derived NGN2 neurons. (A) Workflow diagram and timeline for rapid, single-step generation of NGN2 neurons from human skin-derived iPSCs. Differentiated NGN2 neurons express green fluorescent protein (green), and are subjected to H₂O₂ to induce oxidative stress (red). High-content phenotypic screening is performed using both IncuCyte (for live cell monitoring) and Array Scan (for quantification of neuronal morphology and immunostaining). (B) Heat map of changes in transcriptional profiles of

3

NGN2 neurons after differentiation from iPSCs. All genes listed in this heat map as expressed by NGN2 neurons are also expressed in spiral ganglion neurons, except CHAT and PHOX2B. Mean expression levels from 3 different batches of NGN2 neurons are plotted. The cutoff value for saturating expression is set to 200 reads per million amplicons. The cutoff value for no expression is set to less than 10 reads per million amplicons. (C) Representative immunofluorescence images showing morphological and translational changes that characterize differentiation from iPSCs (expressing TRA-1-60 and NANOG) to NGN2 neurons (expressing EGFP and TUJ1). Scale bar 400 μ m (iPSCs) and 50 μ m (NGN2 neurons).

FIGS. 3A-B. Acoustic trauma model in human iPSC-derived NGN2 neurons. (A) NGN2 neurons were treated with different concentrations of H_2O_2 to simulate oxidative stress and resulting changes in neuronal number, maximal neurite outgrowth, mean cell body area, neurite width and LDH levels in culture media were quantified. 3 μ M H_2O_2 , tended to be most toxic (red rectangle). (B) NGN2 neuronal morphology before and after treatment with 3 μ M H_2O_2 . Neurofilament stained with TuJ antibody (red). Nuclei stained with DAPI (blue).

FIGS. 4A-M. FGF2 protects human iPSC-derived NGN2 neurons from H_2O_2 -induced oxidative stress. (A) Workflow diagram and timeline for drug testing using stressed NGN2 neurons derived from human iPSCs. (B) Number of neurons, (C) maximal neurite outgrowth per neuron and (D) LDH release (absorbance at 490 nm) per neuron as a function of increasing FGF2 concentration in the absence of the H_2O_2 stressor or (E-G) following 3 μ M H_2O_2 stress. Gray bars represent responses when control media was used (without H_2O_2 or FGF2). Each dot represents a separate experiment (N=3). Bars depict mean \pm SEM. *: $p<0.05$; **: $p<0.01$. (H-M): Representative images of NGN2 neurons after various experimental manipulations. (H) Control NGN2 neurons, not exposed to H_2O_2 or treated with FGF2. (I) Morphologic neuronal damage caused by exposure to 3 μ M H_2O_2 . (J) Neurite outgrowth stimulated by FGF2 at 400 ng/ml. (K) Neurons rescued from 3 μ M H_2O_2 -inflicted damage by post-treatment with FGF2 (400 ng/ml). (L) 100 μ M H_2O_2 exposure is less toxic than 3 μ M H_2O_2 exposure (H). (M) FGF2 at 2000 ng/ml is very toxic. NGN2 neurons express green GFP. Neurofilament is stained with TuJ antibody. DAPI labels nuclei.

FIGS. 5A-B. FGF-2 treatment rescues wave I ABR amplitude after neuropathic noise exposure in vivo and regenerates synapses at the IHC-SGN synapse in vitro. (A) Daily systemic FGF-2 administration for two weeks after exposure to 8-16 kHz noise at 97 dB SPL for 2 hours led to recovery of wave I ABR amplitude at 32 kHz—the frequency region of maximal neuropathic damage. Control, vehicle-treated animals demonstrated a statistically significant reduction in wave I ABR amplitude: 80 dB (**** $P<0.0001$) and 75 dB (* $P=0.0329$). N=4 ears for each group. (B) Cochlear explants were incubated with kainic acid (KA) for 2 h and treated with FGF-2 or media-only for 24 h. Quantification of CtBP2 and PSD95 juxtapositions per hair cell in cochlear explants normalized to media-only treatment. Data are presented as means \pm SEM. N=6-11 explants per group. * $P=0.0107$, **** $P<0.0001$. IHC, inner hair cell. SGN, spiral ganglion neuron.

DETAILED DESCRIPTION

SNHL originates from defects in the cochlea, the tiny, snail-shaped organ that lies nestled within the densest bone

4

in the human body (FIG. 1). Hearing begins when sound-induced vibrations of the tympanic membrane and middle ear bones are transmitted to cochlear fluids, leading to stimulation of sensory hair cells, neurotransmitter release, excitation of the auditory nerve, and transmission of the neural impulses through the auditory nuclei in the brainstem, midbrain, and thalamus to the auditory cortex (FIG. 1). There are approximately 30 different cell types in the cochlea and loss of or damage to any of these cell types can lead to hearing loss.

Common causes of human SNHL include exposure to loud noise and aging, which often damage sensory hair cells, resulting in elevated thresholds on the clinical audiogram. However, recent studies in animal models suggest that well before this overt hearing loss can be measured, a more insidious but likely more common process is taking place that permanently interrupts synaptic communication between sensory inner hair cells and subsets of cochlear nerve fibers³⁻⁵. Whether accompanied by audiometric threshold elevations or not, this “cochlear synaptopathy” alters auditory information processing and is a likely contributor to a variety of perceptual abnormalities, including compromised word recognition ability, difficulties understanding speech in noise, tinnitus, and hyperacusis³. It has long been recognized that word recognition testing is a much more sensitive metric of cochlear neural injury than audiometric thresholds, which can remain normal even when 80-90% of neurons are missing⁶.

The identification of accessible, non-toxic drugs to treat cochlear synaptopathy and SNHL represents a major unmet medical need, as there are no FDA-approved pharmacotherapies for SNHL. Therapies for SNHL are essentially limited to hearing aids, which amplify sound, and cochlear implants, which electrically stimulate the cochlear nerve. However, the efficacy of these devices is variable among individuals and these devices do not restore word recognition to normal. Many new therapies are being developed that aim to restore function to damaged cells and nerves in the cochlea, including next-generation cochlear implants⁷, gene therapy^{8,9}, and other small molecule and nanotherapies^{10,11}. Although numerous drugs and supplements have shown efficacy in animal models of SNHL, very few have translated to the clinic (as reviewed in¹² and¹¹). Recent US clinical trials of compounds with disclosed mechanisms of action most commonly target cell death pathways and oxidative stress pathways known to be associated with SNHL¹¹. None of these approaches specifically target the synaptic loss and neurite retraction that are the hallmarks of cochlear synaptopathy.

Identifying a drug that can promote regeneration of cochlear neurites and synapses would have transformative impact for people with hearing loss because loss of cochlear neurites is thought to be the main mechanism of reduced ability to understand speech, even when audiometric thresholds are not substantially affected. Compromised word understanding is particularly disabling because it continues to be an issue even for the most faithful users of hearing aids and cochlear implants. Consequently, SNHL is physically and emotionally costly to individuals, in addition to being economically costly to society¹⁷. Hearing loss has been linked to cognitive dysfunction¹⁸, dementia¹⁹, increased risk for depression in the elderly²⁰, and social and emotional loneliness²¹.

FGF2
As shown herein, FGF2 (also known as basic FGF, bFGF) can promote synaptic and neurite regeneration in a human model of acoustic trauma. Cellular regeneration via FGF2

can be used to catalyze the restoration of acoustic hearing in people and improve their ability to understand words and speech in noise. The present methods can be used, e.g., in individuals struggling with presently irreversible SNHL and reduced word comprehension, which includes the vast majority of people with noise-induced and age-related SNHL.

FGF2 is a potent molecule with pleiotropic biological effects that is already in clinical trials⁵⁷⁻⁸³ and studies for a variety of diseases where it promotes wound healing, tissue regeneration and angiogenesis. Therefore, FGF2 is an attractive and safe candidate for repurposing in SNHL.

FGF2 has been extensively studied in animal models of hearing loss because FGF2 has known neurotrophic properties and plays important roles in the differentiation and function of the peripheral²² and central nervous system²³. Most animal studies of FGF2 have provided evidence that FGF2 can protect hair cells and cochlear neurons from aminoglycoside-mediated hair cell death²⁴, glutamate neurotoxicity²⁵ and mechanical damage²⁶ in vitro and from acoustic trauma in vivo^{25,27,28}. However, other experiments have found no effect of FGF2 on dissociated murine cochlear neurons²⁹ in vitro or cochlear response to acoustic trauma in vivo³⁰. These mixed results may be explained by small sample sizes and animal models that do not properly recapitulate human SNHL. Taken together, the present observations and the robust body of literature supporting a protective role of FGF2 in the mammalian auditory system strongly suggest that FGF2 can rescue degeneration of synapses and neurites in human neurons that model acoustic trauma.

The present results were unexpected because previous animal experiments had shown mixed results^{24,25,26, 27, 28, 29, 30} and previously published reports by others explicitly attribute the observed improvements in word recognition after FGF2 application to the middle ear to promote tympanic membrane regeneration entirely to the closure of the tympanic membrane. See, e.g., Hakuba et al., *The Laryngoscope* 113, 1352-1355 (2003); Kanemaru et al., *Otology & neurotology: official publication of the American Otological Society, American Neurotology Society [and] European Academy of Otology and Neurotology* 32, 1218-1223 (2011); Omae et al., *Auris Nasus Larynx* 44, 664-671 (2017).

In some embodiments, the FGF2 is recombinant human FGF2 (rhFGF2). An exemplary sequence of human FGF2 is available in GenBank at Acc. No. NP_001997.5. In some embodiments, the FGF2 comprises Prol43-Ser288, e.g., as follows:

(SEQ ID NO: 1)
PALPEDGGSGAFFPGHFKDPKRLYCKNGGFFLRIPHGDGRVDGVREKSDPH
IKLQLQAERGVSIVKVCANRYLAMKEDGRLRLASKCVTDECFFFERLES
NNYNTYRSRKYTSWYVALKRTGQYKLGSKTGPGQKAILFLPMSAKS.

In some embodiments, the sequence includes an additional N-terminal Ala. rhFGF2 can be obtained commercially, e.g., from miltenyi biotech, R&D systems, Akron Biotech, Genscript, See also Aviles et al., *Br J Pharmacol*. 2003 October; 140(4): 637-646.

Methods of Treatment

The methods described herein include methods for the treatment of disorders associated with synaptic loss. In some embodiments, the disorder is sensorineural hearing loss with compromised word recognition. Generally, the methods

include administering a therapeutically effective amount of FGF2 as described herein, to a subject who is in need of, or who has been determined to be in need of, such treatment.

As used in this context, to "treat" means to ameliorate at least one symptom of the disorder associated with synaptic loss. For example, a treatment can result in an increase in synaptic connections, or a decrease in the rate of loss of synapses.

As demonstrated herein, FGF2 can be used for SNHL with compromised word recognition, via localized, minimally invasive transtympanic delivery of FGF2 to the inner ear. Administration of a therapeutically effective amount of FGF2 for the treatment of sensorineural hearing loss with compromised word recognition will result in improved word recognition.

Because cochlear loss of synapses and neurites underlies tinnitus and hyperacusis, FGF2 can be used for treatment of tinnitus and hyperacusis, via localized transtympanic delivery of FGF2 to the inner ear. Administration of a therapeutically effective amount of FGF2 for the treatment of tinnitus will result in reduced tinnitus. Administration of a therapeutically effective amount of FGF2 for the treatment of hyperacusis will result in reduced sensitivity to sound.

FGF2 can also be used for treatment of synaptopathies in developmental or neurodegenerative diseases that affect other parts of the nervous system, including the brain and spinal cord. This could be accomplished via localized delivery of FGF2 to the brain, directly or via the inner ear. These synaptopathies may manifest as neurocognitive decline (such as memory loss and learning deficits) induced by therapies (including radiation, chemotherapy and surgery) for CNS neoplasms; these synaptopathies may manifest as psychiatric disorders (such as depression). Administration of a therapeutically effective amount of FGF2 for the treatment of these diseases will result in improvements in neurocognition and/or mood.

Thus the present methods can include administering an effective amount of FGF2 directly to an affected area, e.g., the inner ear or to the brain. The methods can include identifying a subject as being in need of such treatment. For example, a subject can be identified as having (or diagnosed with) SNHL with compromised word recognition, i.e. word recognition or speech discrimination of less than 80%, using an accepted diagnostic method, e.g., NU-6 by difficulty, CID W-22, Harvard-50. See, e.g., Halpin et al., *Otol Neurotol*, 33 (2012), pp. 907-911; Chen et al., *Otol Neurotol*, 24 (2003), pp. 728-733. In some embodiments, the subject does not have a ruptured or damaged cochlear membrane; otosclerosis; immune mediated SNHL; non-SNHL; ototoxicity; or congenital SNHL.

In some embodiments, the FGF2 is administered in a composition formulated using one or more physiologically acceptable carriers or excipients. In some embodiments, the FGF2 is the only active agent in the composition. In some embodiments, the pharmaceutical composition can be formulated for local or systemic administration, e.g., administration by drops (e.g., otic drops) or injection into the ear or other target tissue, or by implantation of a pump or other sustained release device or composition. The devices and pharmaceutical compositions can be administered directly and/or locally by injection or through surgical placement, e.g., via intratympanic or intracochlear administration, to the inner ear.

The composition can be, e.g., prepared with carriers that will protect the therapeutic compounds against rapid elimination from the body, such as a controlled release formulation, including implants and microencapsulated delivery

systems. Liposomal suspensions (including liposomes targeted to selected cells with monoclonal antibodies to cellular antigens) can also be used as pharmaceutically acceptable carriers. These can be prepared according to methods known to those skilled in the art, for example, as described in U.S. Pat. No. 4,522,811 and Mohammadian et al., *Cell Mol Biol (Noisy-le-grand)* 2017 January 30;63(1):28-33. Nanoparticles, e.g., poly lactic/glycolic acid (PLGA) nanoparticles (see Tamura et al., *Laryngoscope*. 2005 November; 115(11): 2000-5; Ge et al., *Otolaryngol Head Neck Surg.* 2007 October; 137(4):619-23; Horie et al., *Laryngoscope*. 2010 February; 120(2):377-83; Sakamoto et al., *Acta Otolaryngol Suppl.* 2010 November;(563):101-4) can also be used.

Bioabsorbable polymers and hydrogels for use in making matrices or sponges for use in the present methods are known in the art, see, e.g., Paulson et al., *Laryngoscope*. 2008 April; 118(4):706-11 (describing a chitosan-glycero-phosphate (CGP)-hydrogel based drug delivery system), Igai et al., *J Thorac Cardiovasc Surg.* 2007 July; 134(1): 170-5 (describing a gelatin sponge; exemplary gelatin sponges are commercially available, e.g., Gelfoam, from Upjohn Company, Kalamazoo, MI; surgifoam, from ethicon), and Takemoto et al., *Tissue Eng Part A*. 2008 October; 14(10):1629-38 (describing gelatin and gelatin/collagen sponges); other carriers can include thermo-reversible triblock copolymer poloxamer 407 (see, e.g., Wang et al., *Audiol Neurotol.* 2009; 14(6):393-401. Epub 2009 November 16, and Wang et al., *Laryngoscope*. 2011 February; 121(2):385-91); poloxamer-based hydrogels such as the one used in OTO-104 (see, e.g., GB2459910; Wang et al., *Audiol Neurotol* 2009; 14:393-401; and Piu et al., *Otol Neurotol.* 2011 January; 32(1):171-9); Pluronic F-127 (see, e.g., Escobar-Chavez et al., *J Pharm Pharm Sci.* 2006; 9(3):339-5); Pluronic F68, F88, or F108; polyoxyethylene-polyoxypropylene triblock copolymer (e.g., a polymer composed of polyoxypropylene and polyoxyethylene, of general formula E106 P70 E106; see GB2459910, US20110319377 and US20100273864); MPEG-PCL diblock copolymers (Hyun et al., *Biomacromolecules.* 2007 April; 8(4):1093-100. Epub 2007 February 28); hyaluronic acid hydrogels (Borden et al., *Audiol Neurotol.* 2011; 16(1):1-11); gelfoam cubes (see, e.g., Havenith et al., *Hearing Research*, February 2011; 272(1-2):168-177); and gelatin hydrogels (see, e.g., Inaoka et al., *Acta Otolaryngol.* 2009 April; 129(4):453-7); other biodegradable, biocompatible polymers can be used, such as ethylene vinyl acetate, polyanhydrides, polyglycolic acid, collagen, polyorthoesters, and polylactic acid. Tunable self-assembling hydrogels made from natural amino acids L and D can also be used, e.g., as described in Hauser et al e.g. Ac-LD6-COOH (L) e.g. *Biotechnol Adv.* 2012 May-June; 30(3):593-603. Such formulations can be prepared using standard techniques, or obtained commercially, e.g., from Alza Corporation and Nova Pharmaceuticals, Inc.

Implantable pumps are described, e.g., in Gehrke et al., *Int J Pharm.* 2016 Jul. 25; 509(1-2):85-94.

In addition to the formulations described above, the compositions can also be formulated as a depot preparation. Such long acting formulations can be administered by implantation (e.g., into the inner ear). Thus, for example, the compositions can be formulated with suitable polymeric or hydrophobic materials (for example as an emulsion in an acceptable oil) or ion exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt, or mixed with chemical permeation enhancers.

For additional information on methods that can be used for drug delivery to the inner ear, see, e.g., Salt and Plontke, *Audiol Neurotol.* 2009 November; 14(6): 350-360; Kechai

et al., *Int J Pharm.* 2015 Oct. 15; 494(1):83-101; Salt and Hirose, *Hear Res.* 2018 May; 362:25-37; Rivera et al., *Curr Drug Deliv.* 2012 May; 9(3):231-42; Musazzi et al., *Drug Deliv Transl Res.* 2018 April; 8(2):436-449; Liu et al., *Drug Dev Ind Pharm.* 2018 September; 44(9):1395-1408; Glueckert et al., *Hear Res.* 2018 October; 368:10-27; Nyberg et al., *Sci Transl Med.* 2019 Mar. 6; 11(482). pii: eaao0935.

In some embodiments, the method comprise administering 10-50, e.g., 15-25, e.g., 20 µg rhFGF2, e.g., about 0.1 to 0.5 mL, e.g., about 0.2 mL of 100 µg/mL of FGF2, in a polymer matrix, e.g., in a gelatin matrix/sponge.

EXAMPLES

The invention is further described in the following examples, which do not limit the scope of the invention described in the claims.

Example 1. Human In Vitro Model of SNHL

We have developed a novel human in vitro model of SNHL using induced pluripotent stem cell (iPSC)-derived glutaminergic neurons that can be used to evaluate promising therapeutics. The major advantage of an iPSC-based approach to human hearing loss modeling and drug testing is that iPSCs are renewable, genetically representative, and capable of generating the quantities of cells necessary to conduct a robust drug study. Using human iPSCs, the first human cellular model of acoustic trauma was developed (FIGS. 2A-C). We focus on generating and evaluating glutaminergic neurons because glutamate is the main afferent neurotransmitter in the cochlea, and a robust method exists by which iPSCs can be induced into glutaminergic neurons quickly, in a single step, with nearly 100% yield and purity, by forced expression of a single transcription factor, neurogenin (NGN2)³⁹. Although these “NGN2 neurons” have characteristics of cortical glutaminergic neurons, they are nonetheless useful in modeling cochlear synaptopathy because these neurons express many genes that are also expressed by spiral ganglion neurons (SGN) (FIG. 2B). For example, TUBB3 gene encoding class III β-Tubulin has been immunohistochemically detected in human SGNs⁴⁰, and is routinely used by us (e.g. ^{41,42}) and others to label rodent SGNs. NTRK2 gene encoding Neurotrophic Receptor Tyrosine Kinase 2 (also known as TRK-B) is the receptor for brain-derived neurotrophic factor, and is known to be abundantly expressed in rodent SGNs (e.g. ⁴³) SLC17A7 (also known as VGLUT1) encodes vesicular glutamate transporter 1, which has been reported in rodent SGNs (e.g. ⁴⁴). Voltage gated potassium channels play key roles in hearing and subunits KCNQ2 and KCNQ3 have been detected in mouse and guinea pig SGNs⁴⁵. In fact, all but two neuronal and sensory neuronal genes listed in FIG. 2B (genes CHAT and PHOX2B) are known to be expressed in SGNs.

Because NGN2 neurons are generated by transducing iPSCs with a lentiviral vector expressing Ngn2 along with a puromycin resistance gene (to allow selection for cells expressing Ngn2) and a lentiviral vector expressing enhanced green fluorescent protein (eGFP), successfully transduced NGN2 neurons express eGFP (FIG. 2C). This allows easy tracking of neurons in culture and quantification of their morphology.

To model synaptopathy due to acoustic trauma, we have induced oxidative stress causing nerve injury by H₂O₂. We chose this stressors because we⁴⁶ and others⁴⁷⁻⁴⁹ have used animal models to demonstrate that H₂O₂ successfully mim-

ics oxidative stress in neurons, and oxidative stress is a primary initial event in the degenerative cascade observed after noise exposure⁵⁰⁻⁵². We show that H₂O₂ treatment of iPSC-derived NGN2 neurons tends to cause loss of neurites and synapses and induce cellular stress, as measured by lactate dehydrogenase (LDH) secretion into culture media. LDH is a robust marker of cell stress and death^{53,54}, and has been extensively used to evaluate neurotoxicity of various drugs^{55,56}.

For every experimental manipulation, untreated cells have served as controls. We have defined an H₂O₂ concentration that effectively tended to cause degeneration of synapses and neurites in our 2D model of acoustic trauma (FIGS. 3A-B). To avoid erroneous estimates of neurite or synaptic counts, we verified automated counts using manual counts.

We next studied FGF2's efficacy in promoting synaptic and neurite regeneration in NGN2 neurons following H₂O₂-induced stress (FIGS. 4A-M). For every experimental manipulation, untreated cells served as controls. Based on assessing a range of FGF2 concentrations applied to H₂O₂-stressed iPSC-derived NGN2 neurons, 400 ng/ml appears to be an effective therapeutic dose for FGF2 to promote neurite extension in human NGN2 neurons (FIGS. 4A-M). We have also identified a toxic concentration of FGF2 (2000 ng/ml), highlighting the need to carefully define the dose-response curve for FGF2.

When comparing responses from control and stressed or treated iPSC-derived NGN2 neurons, we have used t-tests (two-tailed, unpaired)/ANOVA for continuous data and rank tests for nonparametric data (e.g. intensity of immunostaining), with Benjamini-Hochberg correction for multiple hypothesis testing. The multiple comparison-adjusted p values <0.05 are considered statistically significant.

Example 2. FGF-2 Treatment Rescues Wave I ABR Amplitude after Neuropathic Noise Exposure In Vivo and Regenerates Synapses at the IHC-SGN Synapse In Vitro

Methods

The following materials and methods were used in this Example.

Animals and Experimental Design:

Male CBA/CAJ mice were purchased from Jackson Laboratories. Seven-weeks-old mice were exposed to a noise band known to destroy cochlear synapses and cause cochlear neuropathy. Mice were randomly assigned to a group receiving a subcutaneous (SC) injection of 0.5 µg FGF-2 (N=2 animals) or a control group receiving SC injection of vehicle (saline) (N=2 animals) daily for 14 days starting immediately after noise exposure. Fourteen days after noise exposure, cochlear function was assessed with ABRs and DPOAEs in each ear. All experimental procedures were approved by the Institutional Animal Care and Use Committee of Massachusetts Eye and Ear and conducted in accordance with the NIH Guide for the Care and Use of Laboratory Animals.

Noise Exposure:

Mice were exposed to octave-band noise (8-16 kHz) for 2 h at 97 dB sound pressure level (SPL) in a reverberant, acoustically-transparent wire box on a rotating platform. Animals were awake and unrestrained during noise exposure. The noise was created digitally using a fifth-order Butterworth filter, amplified through a power amplifier (Crown D75A), and delivered by a loudspeaker (JBL2446H) coupled to an exponential horn in the roof of the box.

Exposure levels were measured in each cage with a 0.25-inch Brüel and Kjær condenser microphone.

Cochlear Function Testing:

ABRs and DPOAEs were recorded as detailed previously (Jensen et al., 2015; Suzuki et al., 2016). The mice were anesthetized with ketamine (100 mg/kg) and xylazine (10 mg/kg) administered intraperitoneally. A custom acoustic system was used consisting of two miniature earphones serving as sound sources (CDMG150 008-03A, CUI) and a microphone (FG-23329-PO7, Knowles) coupled to a probe tube to measure sound pressure near the eardrum. DPOAEs were measured as ear canal pressure in response to two tones presented into the ear canal (f1 and f2, with f2/f1=1.2) at half octave steps, from f2=5.66-45.25 kHz, and in 5 dB intensity increments from 15 to 80 dB SPL. ABR responses to 5 ms tone pips were measured between subdermal electrodes (positive behind the ipsilateral pinna, negative at the vertex, and ground at the tail), amplified 10,000 times and filtered (0.3-3.0 kHz). For each frequency and sound level, 512 responses were recorded and averaged using custom LabVIEW data-acquisition software run on a PXI chassis (National Instruments Corp., Austin, Texas). The ABR waveforms were stacked from lowest to highest SPL, and visually inspected to define threshold as the first level at which a repeatable wave I was detected. ABR data were acquired in 5 dB intensity increments. ABR wave I amplitude was measured peak-to-peak using the ABR Peak Analysis software (Eaton-Peabody Laboratories). Cochlear function testing and data quantification was performed by the researcher blinded to the treatment group.

In Vitro Model of Cochlear Synaptopathy:

Cochlear explant cultures were prepared as previously described by our laboratory (Landegger, Dilwali, & Stankovic, 2017). Briefly, postnatal day 4 CBA/CAJ wild-type mice (Jackson Laboratory, ME) were decapitated, the temporal bones extracted and the otic capsule dissected away from the cochleae in Hank's Balanced Salt Solution (Life Technologies, NY). The spiral ligament and stria vascularis were gently stripped away from base to apex. The middle part was carefully dissected into a more apical and more basal part, containing sensory hair cells and spiral ganglion neurons. The tectorial and Reissner's membrane were removed. Explants were left overnight to attach onto 10 mm glass coverslips coated with Cell-Tak (BD Biosciences, CA, #354241) in a 35 mm culture dish with 4 wells in culture medium consisting of 98% DMEM, 1% ampicillin, and 1% N2 supplement at 37° C. and 5% CO2 levels in sterile conditions. After microscopically confirming attachment, explants were treated with 0.5 mM kainic acid (Abcam, MA; #ab120100) diluted in culture medium to induce glutamatergic excitotoxicity (Kempfle et al., 2018; Q. Wang & Green, 2011; Yamahara et al., 2019). After 2 h, medium was exchanged, and explants cultured in either culture medium or supplemented with recombinant mouse FGF-2/bFGF (R&D Systems; #3139-FB) at 0.5 or 1 µg/ml. After treatment, cochlear explants were rinsed in PBS, fixed with 4% paraformaldehyde (Electron Microscopy Sciences, PA) in PBS for 20 minutes, washed with PBS and blocked in a blocking buffer consisting of 5% Normal Horse Serum (NHS, Sigma-Aldrich, MO) with 1% Triton-X (Integra Chemical, WA) for ½ hour at room temperature. Following primary antibodies diluted in 1% normal horse serum with 0.3% TX were used for immunostaining and incubated with over-night at room temperature: rabbit anti-myosin 7A at 1:500 (Proteus Biosciences; #25-6790) to label hair cells; mouse (IgG1) anti-CtBP2 (C-terminal Binding Protein) at 1:1000 (#612044, BD Transduction Labs) to label pre-

synaptic ribbons; mouse (IgG2a) anti-PSD95 (post-synaptic density 95) at 1:1000 (#75-028, Neuromab) to label post-synaptic neural synapse patches. After washing in PBS three times, explants were incubated in species-appropriate secondary antibodies at 1:500 dilution for 1½ hours: Alexa Fluor 647-conjugated goat anti-mouse (IgG2a) (#A21131, Life Technologies); Alexa Fluor 568-conjugated goat anti-mouse (IgG1) (#A21124, Life Technologies); Pacific blue-conjugated chicken anti-rabbit (#A21443, Life Technologies). After washing 3 times in PBS, coverslips were mounted on glass slides using Vectashield (Vector Laboratories, CA, #H-1000) and the edges sealed with clear nail polish (Electron Microscopy Sciences, PA). Specimens were imaged with a Leica SP8 confocal microscope. First at 20× for an overview of the specimen. Then, focusing separately on standardized areas to the explant's right and left, images were taken at 63× and with additional 2.4× digital zoom to visualize the entire organ of Corti and the inner hair cell—neurite synapse, respectively. Z-stacks were transferred to Amira imaging software (Visage Imaging, version 5.2.2). Connected components and iso-surface functions were used to create 3D renderings to count for synaptic juxtapositions as previously described (Suzuki et al., 2016). Quantification was performed by the researcher blinded to the treatment group.

Statistical Analysis:

Statistical analysis was performed using GraphPad Prism 8.2.1. Statistical significance in ABR wave I amplitude was determined using ordinary two-way ANOVA with subsequent Tukey's multiple comparisons test. For in vitro synaptic juxtapositions, Tukey's multiple comparison test was employed following one-way ANOVA. A probability value of $P < 0.05$ was considered statistically significant. All data are presented as means ± standard errors of the mean (SEMs). Results

As shown in FIG. 5A, daily systemic FGF-2 administration for two weeks after exposure to 8-16 kHz noise at 97 dB SPL for 2 hours led to recovery of wave I ABR amplitude at 32 kHz—the frequency region of maximal neuropathic damage. Control, vehicle-treated animals demonstrated a statistically significant reduction in wave I ABR amplitude: 80 dB ($P < 0.0001$) and 75 dB ($P = 0.0329$).

As shown in FIG. 5B, when cochlear explants were incubated with kainic acid for 2 h and treated with FGF-2 or media-only, the number of CtBP2 and PSD95 juxtapositions per hair cell in cochlear explants was significantly increased.

OTHER EMBODIMENTS

It is to be understood that while the invention has been described in conjunction with the detailed description thereof, the foregoing description is intended to illustrate and not limit the scope of the invention, which is defined by the scope of the appended claims. Other aspects, advantages, and modifications are within the scope of the following claims.

SEQUENCE LISTING

What is claimed is:

1. A method of treating a subject who has cochlear synaptopathy and does not have tympanic membrane damage or rupture, the method comprising:

identifying a subject who has cochlear synaptopathy but 5
who does not have tympanic membrane damage or rupture; and

administering to the subject a therapeutically effective amount of Fibroblast growth factor 2 (FGF2) to the inner ear,

wherein the therapeutically effective amount of FGF2 is 10
an amount sufficient to improve word recognition in the subject.

2. The method of claim 1, wherein the FGF2 is delivered via transtympanic delivery.

3. The method of claim 1, wherein the FGF2 is administered by intratympanic administration.

4. The method of claim 3, wherein the FGF2 is administered by implantation of a bioabsorbable matrix that releases FGF2 over time.

20

5. The method of claim 4, wherein the bioabsorbable matrix comprises gelatin.

6. The method of claim 1, wherein the method further comprises measuring wave I ABR before and after treatment.

7. A method of regenerating cochlear synapses in a subject, the method comprising:

identifying a subject who has a loss of cochlear synapses, but who does not have tympanic membrane damage or rupture; and

administering to the subject a therapeutically effective amount of FGF2 to the inner ear.

8. The method of claim 7, wherein the FGF2 is delivered via transtympanic delivery.

9. The method of claim 8, wherein the FGF2 is an amount sufficient to improve word recognition in the subject.
