ABSTRACT

System and method of more efficiently identifying and segmenting anatomical structures from 2-D cone beam CT images, rather than from reconstructed 3-D volume data, is disclosed. An image processing system receives, from a cone beam CT device, at least one 2-D x-ray image, which is part of a set of x-ray images taken from a 360 degree scan of a patient with a cone beam CT imaging device. The x-ray image contains at least one anatomical structure such as vertebral bodies to be segmented. The received x-ray is then analyzed in order to identify and segment the anatomical structure contained in the x-ray image based on a stored model of anatomical structures. Once the 360 degree spin is completed, a 3-D image volume from the x-ray image set is created. The identification and segmentation information derived from the x-ray image is then added to the created 3-D image volume.

**AUTO SEGMENTATION USING 2-D IMAGES
TAKEN DURING 3-D IMAGING SPIN****CROSS-REFERENCE TO RELATED
APPLICATIONS**

[0001] This application is a continuation of U.S. patent application Ser. No. 18/588,266 filed on Feb. 27, 2024, which is a continuation application of U.S. patent application Ser. No. 17/088,975 filed on Nov. 4, 2020, which is incorporated in its entirety herein.

TECHNICAL FIELD

[0002] The present invention relates to surgical imaging systems, and in particular, system for automatically segmenting anatomical structures.

BACKGROUND

[0003] Automatic segmentation of a two dimensional (2-D) image or three dimensional (3-D) image volume refers to the process of automatically delineating boundaries between adjacent structures and optionally correctly identifying each structure. For example, successful auto segmentation of a previously unviewed X-ray image of a spine means that each vertebra or vertebral body in the image is automatically highlighted or outlined and also that each vertebra is automatically or semi-automatically correctly identified ("L2", "L3", etc.).

[0004] Methods exist using deep learning or neural networks for training computer models to recognize structures within an image plane or volume by comparing a new image to a set of known images. Because scanning an image volume is more complex computationally than scanning a 2-D image plane, the process for auto segmenting a 3-D image volume, e.g., Computed Tomography (CT) scan, can be slower than the process for auto segmenting a plain 2-D x-ray. Moreover, 3-D image segmentation accuracy can be dependent upon the seeding of the software's starting point through user input.

[0005] By contrast, segmentation software for identifying structures in a 2-D image plane, such as the vertebral levels in a 2-D x-ray image of a spine region, is faster and less dependent on seeding, but tends to be less reliable than the corresponding 3-D segmentation software because there is less information in a 2-D image.

[0006] Therefore, there is a need for a system and method for combining the speed of 2-D segmentation with the accuracy of 3-D segmentation.

SUMMARY OF THE INVENTION

[0007] According to an aspect of the present invention, a method of identifying and segmenting anatomical structures from cone beam CT images is disclosed. An image processing system receives, from a cone beam CT device, at least one x-ray image, which is part of a set of x-ray images taken from a 360 degree scan of a patient with a cone beam CT imaging device. The x-ray image contains at least one anatomical structure to be segmented. The received x-ray is then analyzed in order to identify and segment the at least one anatomical structure contained in the x-ray image based on a stored model of anatomical structures. Once the 360 degree spin is completed, a 3-D image volume from the x-ray image set is created. The identification and segmen-

tation information derived from the x-ray image is then added to the created 3-D image volume.

[0008] Advantageously, the segmentation and identification is made from the 2-D x-ray images rather than from the 3-D image volume. Because the 2-D x-ray images are available as the imaging system spins, processing begins before the spin is completed. Moreover, image processing on 2-D images may be much faster than on 3-D volume. Consequently, the method of the present invention may save a substantial amount of time while being very accurate.

BRIEF DESCRIPTION OF THE DRAWINGS

[0009] FIG. 1 is an overhead view of a potential arrangement for locations of the robotic system, patient, surgeon, and other medical personnel during a surgical procedure;

[0010] FIG. 2 illustrates the robotic system including positioning of the surgical robot and the camera relative to the patient according to one embodiment;

[0011] FIG. 3 illustrates a surgical robotic system in accordance with an exemplary embodiment;

[0012] FIG. 4 illustrates a portion of a surgical robot in accordance with an exemplary embodiment;

[0013] FIG. 5 illustrates a block diagram of a surgical robot in accordance with an exemplary embodiment;

[0014] FIG. 6 illustrates a surgical robot in accordance with an exemplary embodiment;

[0015] FIGS. 7A-7C illustrate an end-effector in accordance with an exemplary embodiment;

[0016] FIG. 8 illustrates a surgical instrument and the end-effector, before and after, inserting the surgical instrument into the guide tube of the end-effector according to one embodiment;

[0017] FIGS. 9A-9C illustrate portions of an end-effector and robot arm in accordance with an exemplary embodiment;

[0018] FIG. 10 illustrates a dynamic reference array, an imaging array, and other components in accordance with an exemplary embodiment;

[0019] FIG. 11 illustrates a method of registration in accordance with an exemplary embodiment;

[0020] FIG. 12A-12B illustrate embodiments of imaging devices according to exemplary embodiments;

[0021] FIG. 13A illustrates a portion of a robot including the robot arm and an end-effector in accordance with an exemplary embodiment;

[0022] FIG. 13B is a close-up view of the end-effector, with a plurality of tracking markers rigidly affixed thereto, shown in FIG. 13A;

[0023] FIG. 13C is a tool or instrument with a plurality of tracking markers rigidly affixed thereto according to one embodiment;

[0024] FIG. 14A is an alternative version of an end-effector with moveable tracking markers in a first configuration;

[0025] FIG. 14B is the end-effector shown in FIG. 14A with the moveable tracking markers in a second configuration;

[0026] FIG. 14C shows the template of tracking markers in the first configuration from FIG. 14A;

[0027] FIG. 14D shows the template of tracking markers in the second configuration from FIG. 14B;

[0028] FIG. 15A shows an alternative version of the end-effector having only a single tracking marker affixed thereto;

- [0029] FIG. 15B shows the end-effector of FIG. 15A with an instrument disposed through the guide tube;
- [0030] FIG. 15C shows the end-effector of FIG. 15A with the instrument in two different positions, and the resulting logic to determine if the instrument is positioned within the guide tube or outside of the guide tube;
- [0031] FIG. 15D shows the end-effector of FIG. 15A with the instrument in the guide tube at two different frames and its relative distance to the single tracking marker on the guide tube;
- [0032] FIG. 15E shows the end-effector of FIG. 15A relative to a coordinate system;
- [0033] FIG. 16 is a block diagram of a method for navigating and moving the end-effector of the robot to a desired target trajectory;
- [0034] FIGS. 17A-17B depict an instrument for inserting an expandable implant having fixed and moveable tracking markers in contracted and expanded positions, respectively;
- [0035] FIGS. 18A-18B depict an instrument for inserting an articulating implant having fixed and moveable tracking markers in insertion and angled positions, respectively;
- [0036] FIGS. 19A and 19B illustrate typical AP and lateral images of a spine;
- [0037] FIG. 20 illustrates a misaligned lateral image of the spine;
- [0038] FIG. 21 illustrates a method of determining the 3-dimensional position of an imaging arm of an imaging device for taking optimal images of a vertebral body according to one aspect of the present invention;
- [0039] FIG. 22 illustrates a calibration ring having tracking markers according to one aspect of the present invention;
- [0040] FIG. 23 is an example of an x-ray imaging device having an automatic positioning capability with respect to the 3D position and orientation of its C-arm according one aspect of the present invention;
- [0041] FIG. 24A is an example of a graphical user interface showing the available selection of images at different vertebral levels according to an aspect of the present invention;
- [0042] FIG. 24B is an example of a graphical user interface showing the additional available selection of images at adjacent vertebral levels according to an aspect of the present invention;
- [0043] FIG. 25 is an example of a graphical user interface that guides a user to position the C-arm at an optimal position according to an aspect of the present invention;
- [0044] FIG. 26 is a representation of a method of performing a segmentation of vertebral bodies according to an aspect of the present invention;
- [0045] FIGS. 27A and 27B graphically illustrate a method of aligning a 3D model of a selected vertebral body to the scanned AP and lateral images according to an aspect of the present invention;
- [0046] FIG. 28 is a flowchart of an image control software for auto segmentation and computation of data related to a 3-D image volume of a 3-D spin of imaging system according an aspect of the present invention;
- [0047] FIG. 29A illustrates a conventional graphical display of the output of the 3-D image volume; and
- [0048] FIG. 29B illustrates a graphical display of the output of the 3-D image volume with the auto segmentation information superimposed according to an aspect of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0049] It is to be understood that the present disclosure is not limited in its application to the details of construction and the arrangement of components set forth in the description herein or illustrated in the drawings. The teachings of the present disclosure may be used and practiced in other embodiments and practiced or carried out in various ways. Also, it is to be understood that the phraseology and terminology used herein is for the purpose of description and should not be regarded as limiting. The use of "including," "comprising," or "having" and variations thereof herein is meant to encompass the items listed thereafter and equivalents thereof as well as additional items. Unless specified or limited otherwise, the terms "mounted," "connected," "supported," and "coupled" and variations thereof are used broadly and encompass both direct and indirect mountings, connections, supports, and couplings. Further, "connected" and "coupled" are not restricted to physical or mechanical connections or couplings.

[0050] The following discussion is presented to enable a person skilled in the art to make and use embodiments of the present disclosure. Various modifications to the illustrated embodiments will be readily apparent to those skilled in the art, and the principles herein can be applied to other embodiments and applications without departing from embodiments of the present disclosure. Thus, the embodiments are not intended to be limited to embodiments shown, but are to be accorded the widest scope consistent with the principles and features disclosed herein. The following detailed description is to be read with reference to the figures, in which like elements in different figures have like reference numerals. The figures, which are not necessarily to scale, depict selected embodiments and are not intended to limit the scope of the embodiments. Skilled artisans will recognize the examples provided herein have many useful alternatives and fall within the scope of the embodiments.

[0051] Turning now to the drawing, FIGS. 1 and 2 illustrate a surgical robot system 100 in accordance with an exemplary embodiment. Surgical robot system 100 may include, for example, a surgical robot 102, one or more robot arms 104, a base 106, a display 110, an end-effector 112, for example, including a guide tube 114, and one or more tracking markers 118. The surgical robot system 100 may include a patient tracking device 116 also including one or more tracking markers 118, which is adapted to be secured directly to the patient 210 (e.g., to the bone of the patient 210). The surgical robot system 100 may also utilize a camera 200, for example, positioned on a camera stand 202. The camera stand 202 can have any suitable configuration to move, orient, and support the camera 200 in a desired position. The camera 200 may include any suitable camera or cameras, such as one or more infrared cameras (e.g., bifocal or stereophotogrammetric cameras), able to identify, for example, active and passive tracking markers 118 in a given measurement volume viewable from the perspective of the camera 200. The camera 200 may scan the given measurement volume and detect the light that comes from the markers 118 in order to identify and determine the position of the markers 118 in three-dimensions. For example, active markers 118 may include infrared-emitting markers that are activated by an electrical signal (e.g., infrared light emitting diodes (LEDs)), and passive markers 118 may include retro-reflective markers that reflect infrared

light (e.g., they reflect incoming IR radiation into the direction of the incoming light), for example, emitted by illuminators on the camera 200 or other suitable device.

[0052] FIGS. 1 and 2 illustrate a potential configuration for the placement of the surgical robot system 100 in an operating room environment. For example, the robot 102 may be positioned near or next to patient 210. Although depicted near the head of the patient 210, it will be appreciated that the robot 102 can be positioned at any suitable location near the patient 210 depending on the area of the patient 210 undergoing the operation. The camera 200 may be separated from the robot system 100 and positioned at the foot of patient 210. This location allows the camera 200 to have a direct visual line of sight to the surgical field 208. Again, it is contemplated that the camera 200 may be located at any suitable position having line of sight to the surgical field 208. In the configuration shown, the surgeon 120 may be positioned across from the robot 102, but is still able to manipulate the end-effector 112 and the display 110. A surgical assistant 126 may be positioned across from the surgeon 120 again with access to both the end-effector 112 and the display 110. If desired, the locations of the surgeon 120 and the assistant 126 may be reversed. The traditional areas for the anesthesiologist 122 and the nurse or scrub tech 124 remain unimpeded by the locations of the robot 102 and camera 200.

[0053] With respect to the other components of the robot 102, the display 110 can be attached to the surgical robot 102 and in other exemplary embodiments, display 110 can be detached from surgical robot 102, either within a surgical room with the surgical robot 102, or in a remote location. End-effector 112 may be coupled to the robot arm 104 and controlled by at least one motor. In exemplary embodiments, end-effector 112 can comprise a guide tube 114, which is able to receive and orient a surgical instrument 608 (described further herein) used to perform surgery on the patient 210. As used herein, the term "end-effector" is used interchangeably with the terms "end-effectuator" and "effectuator element." Although generally shown with a guide tube 114, it will be appreciated that the end-effector 112 may be replaced with any suitable instrumentation suitable for use in surgery. In some embodiments, end-effector 112 can comprise any known structure for effecting the movement of the surgical instrument 608 in a desired manner.

[0054] The surgical robot 102 is able to control the translation and orientation of the end-effector 112. The robot 102 is able to move end-effector 112 along x-, y-, and z-axes, for example. The end-effector 112 can be configured for selective rotation about one or more of the x-, y-, and z-axis, and a Z Frame axis (such that one or more of the Euler Angles (e.g., roll, pitch, and/or yaw) associated with end-effector 112 can be selectively controlled). In some exemplary embodiments, selective control of the translation and orientation of end-effector 112 can permit performance of medical procedures with significantly improved accuracy compared to conventional robots that utilize, for example, a six degree of freedom robot arm comprising only rotational axes. For example, the surgical robot system 100 may be used to operate on patient 210, and robot arm 104 can be positioned above the body of patient 210, with end-effector 112 selectively angled relative to the z-axis toward the body of patient 210.

[0055] In some exemplary embodiments, the position of the surgical instrument 608 can be dynamically updated so

that surgical robot 102 can be aware of the location of the surgical instrument 608 at all times during the procedure. Consequently, in some exemplary embodiments, surgical robot 102 can move the surgical instrument 608 to the desired position quickly without any further assistance from a physician (unless the physician so desires). In some further embodiments, surgical robot 102 can be configured to correct the path of the surgical instrument 608 if the surgical instrument 608 strays from the selected, preplanned trajectory. In some exemplary embodiments, surgical robot 102 can be configured to permit stoppage, modification, and/or manual control of the movement of end-effector 112 and/or the surgical instrument 608. Thus, in use, in exemplary embodiments, a physician or other user can operate the system 100, and has the option to stop, modify, or manually control the autonomous movement of end-effector 112 and/or the surgical instrument 608. Further details of surgical robot system 100 including the control and movement of a surgical instrument 608 by surgical robot 102 can be found in co-pending U.S. patent application Ser. No. 13/924,505, which is incorporated herein by reference in its entirety.

[0056] The robotic surgical system 100 can comprise one or more tracking markers 118 configured to track the movement of robot arm 104, end-effector 112, patient 210, and/or the surgical instrument 608 in three dimensions. In exemplary embodiments, a plurality of tracking markers 118 can be mounted (or otherwise secured) thereon to an outer surface of the robot 102, such as, for example and without limitation, on base 106 of robot 102, on robot arm 104, or on the end-effector 112. In exemplary embodiments, at least one tracking marker 118 of the plurality of tracking markers 118 can be mounted or otherwise secured to the end-effector 112. One or more tracking markers 118 can further be mounted (or otherwise secured) to the patient 210. In exemplary embodiments, the plurality of tracking markers 118 can be positioned on the patient 210 spaced apart from the surgical field 208 to reduce the likelihood of being obscured by the surgeon, surgical tools, or other parts of the robot 102. Further, one or more tracking markers 118 can be further mounted (or otherwise secured) to the surgical tools 608 (e.g., a screw driver, dilator, implant inserter, or the like). Thus, the tracking markers 118 enable each of the marked objects (e.g., the end-effector 112, the patient 210, and the surgical tools 608) to be tracked by the robot 102. In exemplary embodiments, system 100 can use tracking information collected from each of the marked objects to calculate the orientation and location, for example, of the end-effector 112, the surgical instrument 608 (e.g., positioned in the tube 114 of the end-effector 112), and the relative position of the patient 210.

[0057] In exemplary embodiments, one or more of markers 118 may be optical markers. In some embodiments, the positioning of one or more tracking markers 118 on end-effector 112 can maximize the accuracy of the positional measurements by serving to check or verify the position of end-effector 112. Further details of surgical robot system 100 including the control, movement and tracking of surgical robot 102 and of a surgical instrument 608 can be found in co-pending U.S. patent application Ser. No. 13/924,505, which is incorporated herein by reference in its entirety.

[0058] Exemplary embodiments include one or more markers 118 coupled to the surgical instrument 608. In exemplary embodiments, these markers 118, for example, coupled to the patient 210 and surgical instruments 608, as

well as markers 118 coupled to the end-effector 112 of the robot 102 can comprise conventional infrared light-emitting diodes (LEDs) or an Optotak® diode capable of being tracked using a commercially available infrared optical tracking system such as Optotak®. Optotak® is a registered trademark of Northern Digital Inc., Waterloo, Ontario, Canada. In other embodiments, markers 118 can comprise conventional reflective spheres capable of being tracked using a commercially available optical tracking system such as Polaris Spectra. Polaris Spectra is also a registered trademark of Northern Digital, Inc. In an exemplary embodiment, the markers 118 coupled to the end-effector 112 are active markers which comprise infrared light-emitting diodes which may be turned on and off, and the markers 118 coupled to the patient 210 and the surgical instruments 608 comprise passive reflective spheres.

[0059] In exemplary embodiments, light emitted from and/or reflected by markers 118 can be detected by camera 200 and can be used to monitor the location and movement of the marked objects. In alternative embodiments, markers 118 can comprise a radio-frequency and/or electromagnetic reflector or transceiver and the camera 200 can include or be replaced by a radio-frequency and/or electromagnetic transceiver.

[0060] Similar to surgical robot system 100, FIG. 3 illustrates a surgical robot system 300 and camera stand 302, in a docked configuration, consistent with an exemplary embodiment of the present disclosure. Surgical robot system 300 may comprise a robot 301 including a display 304, upper arm 306, lower arm 308, end-effector 310, vertical column 312, casters 314, cabinet 316, tablet drawer 318, connector panel 320, control panel 322, and ring of information 324. Camera stand 302 may comprise camera 326. These components are described in greater with respect to FIG. 5. FIG. 3 illustrates the surgical robot system 300 in a docked configuration where the camera stand 302 is nested with the robot 301, for example, when not in use. It will be appreciated by those skilled in the art that the camera 326 and robot 301 may be separated from one another and positioned at any appropriate location during the surgical procedure, for example, as shown in FIGS. 1 and 2.

[0061] FIG. 4 illustrates a base 400 consistent with an exemplary embodiment of the present disclosure. Base 400 may be a portion of surgical robot system 300 and comprise cabinet 316. Cabinet 316 may house certain components of surgical robot system 300 including but not limited to a battery 402, a power distribution module 404, a platform interface board module 406, a computer 408, a handle 412, and a tablet drawer 414. The connections and relationship between these components is described in greater detail with respect to FIG. 5.

[0062] FIG. 5 illustrates a block diagram of certain components of an exemplary embodiment of surgical robot system 300. Surgical robot system 300 may comprise platform subsystem 502, computer subsystem 504, motion control subsystem 506, and tracking subsystem 532. Platform subsystem 502 may further comprise battery 402, power distribution module 404, platform interface board module 406, and tablet charging station 534. Computer subsystem 504 may further comprise computer 408, display 304, and speaker 536. Motion control subsystem 506 may further comprise driver circuit 508, motors 510, 512, 514, 516, 518, stabilizers 520, 522, 524, 526, end-effector 310, and controller 538. Tracking subsystem 532 may further comprise

position sensor 540 and camera converter 542. System 300 may also comprise a foot pedal 544 and tablet 546.

[0063] Input power is supplied to system 300 via a power source 548 which may be provided to power distribution module 404. Power distribution module 404 receives input power and is configured to generate different power supply voltages that are provided to other modules, components, and subsystems of system 300. Power distribution module 404 may be configured to provide different voltage supplies to platform interface module 406, which may be provided to other components such as computer 408, display 304, speaker 536, driver 508 to, for example, power motors 512, 514, 516, 518 and end-effector 310, motor 510, ring 324, camera converter 542, and other components for system 300 for example, fans for cooling the electrical components within cabinet 316.

[0064] Power distribution module 404 may also provide power to other components such as tablet charging station 534 that may be located within tablet drawer 318. Tablet charging station 534 may be in wireless or wired communication with tablet 546 for charging table 546. Tablet 546 may be used by a surgeon consistent with the present disclosure and described herein.

[0065] Power distribution module 404 may also be connected to battery 402, which serves as temporary power source in the event that power distribution module 404 does not receive power from input power 548. At other times, power distribution module 404 may serve to charge battery 402 if necessary.

[0066] Other components of platform subsystem 502 may also include connector panel 320, control panel 322, and ring 324. Connector panel 320 may serve to connect different devices and components to system 300 and/or associated components and modules. Connector panel 320 may contain one or more ports that receive lines or connections from different components. For example, connector panel 320 may have a ground terminal port that may ground system 300 to other equipment, a port to connect foot pedal 544 to system 300, a port to connect to tracking subsystem 532, which may comprise position sensor 540, camera converter 542, and cameras 326 associated with camera stand 302. [A PORT IN THE CONNECTOR PANEL 320 MAY ALSO CONNECT TO AN IMAGING DEVICE FOR RECEIVING SCANNED IMAGES AND FOR CONTROLLING THE LOCATION AND ORIENTATION OF THE C-ARM BASED ON THE OPTICAL/NAVIGATION MARKERS ATTACHED TO THE IMAGING DEVICE] Connector panel 320 may also include other ports to allow USB, Ethernet, HDMI communications to other components, such as computer 408.

[0067] Control panel 322 may provide various buttons or indicators that control operation of system 300 and/or provide information regarding system 300. For example, control panel 322 may include buttons to power on or off system 300, lift or lower vertical column 312, and lift or lower stabilizers 520-526 that may be designed to engage casters 314 to lock system 300 from physically moving. Other buttons may stop system 300 in the event of an emergency, which may remove all motor power and apply mechanical brakes to stop all motion from occurring. Control panel 322 may also have indicators notifying the user of certain system conditions such as a line power indicator or status of charge for battery 402.

[0068] Ring 324 may be a visual indicator to notify the user of system 300 of different modes that system 300 is operating under and certain warnings to the user.

[0069] Computer subsystem 504 includes computer 408, display 304, and speaker 536. Computer 504 includes an operating system and software to operate system 300. Computer 504 may receive and process information from other components (for example, tracking subsystem 532, platform subsystem 502, and/or motion control subsystem 506) in order to display information to the user. Further, computer subsystem 504 may also include speaker 536 to provide audio to the user.

[0070] Tracking subsystem 532 may include position sensor 504 and converter 542. Tracking subsystem 532 may correspond to camera stand 302 including camera 326 as described with respect to FIG. 3. Position sensor 504 may be camera 326. Tracking subsystem may track the location of certain markers that are located on the different components of system 300 and/or instruments used by a user during a surgical procedure. This tracking may be conducted in a manner consistent with the present disclosure including the use of infrared technology that tracks the location of active or passive elements, such as LEDs or reflective markers, respectively. The location, orientation, and position of structures having these types of markers may be provided to computer 408 which may be shown to a user on display 304. For example, a surgical instrument 608 having these types of markers and tracked in this manner (which may be referred to as a navigational space) may be shown to a user in relation to a three dimensional image of a patient's anatomical structure.

[0071] Motion control subsystem 506 may be configured to physically move vertical column 312, upper arm 306, lower arm 308, or rotate end-effector 310. The physical movement may be conducted through the use of one or more motors 510-518. For example, motor 510 may be configured to vertically lift or lower vertical column 312. Motor 512 may be configured to laterally move upper arm 308 around a point of engagement with vertical column 312 as shown in FIG. 3. Motor 514 may be configured to laterally move lower arm 308 around a point of engagement with upper arm 308 as shown in FIG. 3. Motors 516 and 518 may be configured to move end-effector 310 in a manner such that one may control the roll and one may control the tilt, thereby providing multiple angles that end-effector 310 may be moved. These movements may be achieved by controller 538 which may control these movements through load cells disposed on end-effector 310 and activated by a user engaging these load cells to move system 300 in a desired manner.

[0072] Moreover, system 300 may provide for automatic movement of vertical column 312, upper arm 306, and lower arm 308 through a user indicating on display 304 (which may be a touchscreen input device) the location of a surgical instrument or component on three dimensional image of the patient's anatomy on display 304. The user may initiate this automatic movement by stepping on foot pedal 544 or some other input means.

[0073] FIG. 6 illustrates a surgical robot system 600 consistent with an exemplary embodiment. Surgical robot system 600 may comprise end-effector 602, robot arm 604, guide tube 606, instrument 608, and robot base 610. Instrument tool 608 may be attached to a tracking array 612 including one or more tracking markers (such as markers 118) and have an associated trajectory 614. Trajectory 614

may represent a path of movement that instrument tool 608 is configured to travel once it is positioned through or secured in guide tube 606, for example, a path of insertion of instrument tool 608 into a patient. In an exemplary operation, robot base 610 may be configured to be in electronic communication with robot arm 604 and end-effector 602 so that surgical robot system 600 may assist a user (for example, a surgeon) in operating on the patient 210. Surgical robot system 600 may be consistent with previously described surgical robot system 100 and 300.

[0074] A tracking array 612 may be mounted on instrument 608 to monitor the location and orientation of instrument tool 608. The tracking array 612 may be attached to an instrument 608 and may comprise tracking markers 804. As best seen in FIG. 8, tracking markers 804 may be, for example, light emitting diodes and/or other types of reflective markers (e.g., markers 118 as described elsewhere herein). The tracking devices may be one or more line of sight devices associated with the surgical robot system. As an example, the tracking devices may be one or more cameras 200, 326 associated with the surgical robot system 100, 300 and may also track tracking array 612 for a defined domain or relative orientations of the instrument 608 in relation to the robot arm 604, the robot base 610, end-effector 602, and/or the patient 210. The tracking devices may be consistent with those structures described in connection with camera stand 302 and tracking subsystem 532.

[0075] FIGS. 7A, 7B, and 7C illustrate a top view, front view, and side view, respectively, of end-effector 602 consistent with an exemplary embodiment. End-effector 602 may comprise one or more tracking markers 702. Tracking markers 702 may be light emitting diodes or other types of active and passive markers, such as tracking markers 118 that have been previously described. In an exemplary embodiment, the tracking markers 702 are active infrared-emitting markers that are activated by an electrical signal (e.g., infrared light emitting diodes (LEDs)). Thus, tracking markers 702 may be activated such that the infrared markers 702 are visible to the camera 200, 326 or may be deactivated such that the infrared markers 702 are not visible to the camera 200, 326. Thus, when the markers 702 are active, the end-effector 602 may be controlled by the system 100, 300, 600, and when the markers 702 are deactivated, the end-effector 602 may be locked in position and unable to be moved by the system 100, 300, 600. Markers 702 may be disposed on or within end-effector 602 in a manner such that the markers 702 are visible by one or more cameras 200, 326 or other tracking devices associated with the surgical robot system 100, 300, 600. The camera 200, 326 or other tracking devices may track end-effector 602 as it moves to different positions and viewing angles by following the movement of tracking markers 702. The location of markers 702 and/or end-effector 602 may be shown on a display 110, 304 associated with the surgical robot system 100, 300, 600, for example, display 110 as shown in FIG. 2 and/or display 304 shown in FIG. 3. This display 110, 304 may allow a user to ensure that end-effector 602 is in a desirable position in relation to robot arm 604, robot base 610, the patient 210, and/or the user.

[0076] For example, as shown in FIG. 7A, markers 702 may be placed around the surface of end-effector 602 so that a tracking device placed away from the surgical field 208 and facing toward the robot 102, 301 and the camera 200, 326 is able to view at least 3 of the markers 702 through a

range of common orientations of the end-effector 602 relative to the tracking device 100, 300, 600. For example, distribution of markers 702 in this way allows end-effector 602 to be monitored by the tracking devices when end-effector 602 is translated and rotated in the surgical field 208.

[0077] In addition, in exemplary embodiments, end-effector 602 may be equipped with infrared (IR) receivers that can detect when an external camera 200, 326 is getting ready to read markers 702. Upon this detection, end-effector 602 may then illuminate markers 702. The detection by the IR receivers that the external camera 200, 326 is ready to read markers 702 may signal the need to synchronize a duty cycle of markers 702, which may be light emitting diodes, to an external camera 200, 326. This may also allow for lower power consumption by the robotic system as a whole, whereby markers 702 would only be illuminated at the appropriate time instead of being illuminated continuously. Further, in exemplary embodiments, markers 702 may be powered off to prevent interference with other navigation tools, such as different types of surgical instruments 608.

[0078] FIG. 8 depicts one type of surgical instrument 608 including a tracking array 612 and tracking markers 804. Tracking markers 804 may be of any type described herein including but not limited to light emitting diodes or reflective spheres. Markers 804 are monitored by tracking devices associated with the surgical robot system 100, 300, 600 and may be one or more of the line of sight cameras 200, 326. The cameras 200, 326 may track the location of instrument 608 based on the position and orientation of tracking array 612 and markers 804. A user, such as a surgeon 120, may orient instrument 608 in a manner so that tracking array 612 and markers 804 are sufficiently recognized by the tracking device or camera 200, 326 to display instrument 608 and markers 804 on, for example, display 110 of the exemplary surgical robot system.

[0079] The manner in which a surgeon 120 may place instrument 608 into guide tube 606 of the end-effector 602 and adjust the instrument 608 is evident in FIG. 8. The hollow tube or guide tube 114, 606 of the end-effector 112, 310, 602 is sized and configured to receive at least a portion of the surgical instrument 608. The guide tube 114, 606 is configured to be oriented by the robot arm 104 such that insertion and trajectory for the surgical instrument 608 is able to reach a desired anatomical target within or upon the body of the patient 210. The surgical instrument 608 may include at least a portion of a generally cylindrical instrument. Although a screw driver is exemplified as the surgical tool 608, it will be appreciated that any suitable surgical tool 608 may be positioned by the end-effector 602. By way of example, the surgical instrument 608 may include one or more of a guide wire, cannula, a retractor, a drill, a reamer, a screw driver, an insertion tool, a removal tool, or the like. Although the hollow tube 114, 606 is generally shown as having a cylindrical configuration, it will be appreciated by those of skill in the art that the guide tube 114, 606 may have any suitable shape, size and configuration desired to accommodate the surgical instrument 608 and access the surgical site.

[0080] FIGS. 9A-9C illustrate end-effector 602 and a portion of robot arm 604 consistent with an exemplary embodiment. End-effector 602 may further comprise body 1202 and clamp 1204. Clamp 1204 may comprise handle 1206, balls 1208, spring 1210, and lip 1212. Robot arm 604 may further comprise depressions 1214, mounting plate

1216, lip 1218, and magnets 1220. End-effector 602 may mechanically interface and/or engage with the surgical robot system and robot arm 604 through one or more couplings. For example, end-effector 602 may engage with robot arm 604 through a locating coupling and/or a reinforcing coupling. Through these couplings, end-effector 602 may fasten with robot arm 604 outside a flexible and sterile barrier. In an exemplary embodiment, the locating coupling may be a magnetically kinematic mount and the reinforcing coupling may be a five bar over center clamping linkage.

[0081] With respect to the locating coupling, robot arm 604 may comprise mounting plate 1216, which may be non-magnetic material, one or more depressions 1214, lip 1218, and magnets 1220. Magnet 1220 is mounted below each of depressions 1214. Portions of clamp 1204 may comprise magnetic material and be attracted by one or more magnets 1220. Through the magnetic attraction of clamp 1204 and robot arm 604, balls 1208 become seated into respective depressions 1214. For example, balls 1208 as shown in FIG. 9B would be seated in depressions 1214 as shown in FIG. 9A. This seating may be considered a magnetically-assisted kinematic coupling. Magnets 1220 may be configured to be strong enough to support the entire weight of end-effector 602 regardless of the orientation of end-effector 602. The locating coupling may be any style of kinematic mount that uniquely restrains six degrees of freedom.

[0082] With respect to the reinforcing coupling, portions of clamp 1204 may be configured to be a fixed ground link and as such clamp 1204 may serve as a five bar linkage. Closing clamp handle 1206 may fasten end-effector 602 to robot arm 604 as lip 1212 and lip 1218 engage clamp 1204 in a manner to secure end-effector 602 and robot arm 604. When clamp handle 1206 is closed, spring 1210 may be stretched or stressed while clamp 1204 is in a locked position. The locked position may be a position that provides for linkage past center. Because of a closed position that is past center, the linkage will not open absent a force applied to clamp handle 1206 to release clamp 1204. Thus, in a locked position end-effector 602 may be robustly secured to robot arm 604.

[0083] Spring 1210 may be a curved beam in tension. Spring 1210 may be comprised of a material that exhibits high stiffness and high yield strain such as virgin PEEK (poly-ether-ether-ketone). The linkage between end-effector 602 and robot arm 604 may provide for a sterile barrier between end-effector 602 and robot arm 604 without impeding fastening of the two couplings.

[0084] The reinforcing coupling may be a linkage with multiple spring members. The reinforcing coupling may latch with a cam or friction based mechanism. The reinforcing coupling may also be a sufficiently powerful electromagnet that will support fastening end-effector 102 to robot arm 604. The reinforcing coupling may be a multi-piece collar completely separate from either end-effector 602 and/or robot arm 604 that slips over an interface between end-effector 602 and robot arm 604 and tightens with a screw mechanism, an over center linkage, or a cam mechanism.

[0085] Referring to FIGS. 10 and 11, prior to or during a surgical procedure, certain registration procedures may be conducted in order to track objects and a target anatomical structure of the patient 210 both in a navigation space and an

image space. In order to conduct such registration, a registration system **1400** may be used as illustrated in FIG. 10.

[0086] In order to track the position of the patient **210**, a patient tracking device **116** may include a patient fixation instrument **1402** to be secured to a rigid anatomical structure of the patient **210** and a dynamic reference base (DRB) **1404** may be securely attached to the patient fixation instrument **1402**. For example, patient fixation instrument **1402** may be inserted into opening **1406** of dynamic reference base **1404**. Dynamic reference base **1404** may contain markers **1408** that are visible to tracking devices, such as tracking subsystem **532**. These markers **1408** may be optical markers or reflective spheres, such as tracking markers **118**, as previously discussed herein.

[0087] Patient fixation instrument **1402** is attached to a rigid anatomy of the patient **210** and may remain attached throughout the surgical procedure. In an exemplary embodiment, patient fixation instrument **1402** is attached to a rigid area of the patient **210**, for example, a bone that is located away from the targeted anatomical structure subject to the surgical procedure. In order to track the targeted anatomical structure, dynamic reference base **1404** is associated with the targeted anatomical structure through the use of a registration fixture that is temporarily placed on or near the targeted anatomical structure in order to register the dynamic reference base **1404** with the location of the targeted anatomical structure.

[0088] A registration fixture **1410** is attached to patient fixation instrument **1402** through the use of a pivot arm **1412**. Pivot arm **1412** is attached to patient fixation instrument **1402** by inserting patient fixation instrument **1402** through an opening **1414** of registration fixture **1410**. Pivot arm **1412** is attached to registration fixture **1410** by, for example, inserting a knob **1416** through an opening **1418** of pivot arm **1412**.

[0089] Using pivot arm **1412**, registration fixture **1410** may be placed over the targeted anatomical structure and its location may be determined in an image space and navigation space using tracking markers **1420** and/or fiducials **1422** on registration fixture **1410**. Registration fixture **1410** may contain a collection of markers **1420** that are visible in a navigational space (for example, markers **1420** may be detectable by tracking subsystem **532**). Tracking markers **1420** may be optical markers visible in infrared light as previously described herein.

[0090] Registration fixture **1410** may also contain a collection of fiducials **1422**, for example, such as bearing balls, that are visible in an imaging space (for example, a three dimension CT image). As described in greater detail with respect to FIG. 11, using registration fixture **1410**, the targeted anatomical structure may be associated with dynamic reference base **1404** thereby allowing depictions of objects in the navigational space to be overlaid on images of the anatomical structure. Dynamic reference base **1404**, located at a position away from the targeted anatomical structure, may become a reference point thereby allowing removal of registration fixture **1410** and/or pivot arm **1412** from the surgical area.

[0091] FIG. 11 provides an exemplary method **1500** for registration consistent with the present disclosure. Method **1500** begins at step **1502** wherein a graphical representation (or image(s)) of the targeted anatomical structure may be imported into system **100, 300 600**, for example computer **408**. The graphical representation may be three dimensional

CT or a fluoroscope scan of the targeted anatomical structure of the patient **210** which includes registration fixture **1410** and a detectable imaging pattern of fiducials **1420**.

[0092] At step **1504**, an imaging pattern of fiducials **1420** is detected and registered in the imaging space and stored in computer **408**. Optionally, at this time at step **1506**, a graphical representation of the registration fixture **1410** may be overlaid on the images of the targeted anatomical structure.

[0093] At step **1508**, a navigational pattern of registration fixture **1410** is detected and registered by recognizing markers **1420**. Markers **1420** may be optical markers that are recognized in the navigation space through infrared light by tracking subsystem **532** via position sensor **540**. Thus, the location, orientation, and other information of the targeted anatomical structure is registered in the navigation space. Therefore, registration fixture **1410** may be recognized in both the image space through the use of fiducials **1422** and the navigation space through the use of markers **1420**. At step **1510**, the registration of registration fixture **1410** in the image space is transferred to the navigation space. This transferal is done, for example, by using the relative position of the imaging pattern of fiducials **1422** compared to the position of the navigation pattern of markers **1420**.

[0094] At step **1512**, registration of the navigation space of registration fixture **1410** (having been registered with the image space) is further transferred to the navigation space of dynamic registration array **1404** attached to patient fixture instrument **1402**. Thus, registration fixture **1410** may be removed and dynamic reference base **1404** may be used to track the targeted anatomical structure in both the navigation and image space because the navigation space is associated with the image space.

[0095] At steps **1514** and **1516**, the navigation space may be overlaid on the image space and objects with markers visible in the navigation space (for example, surgical instruments **608** with optical markers **804**). The objects may be tracked through graphical representations of the surgical instrument **608** on the images of the targeted anatomical structure.

[0096] FIGS. 12A-12B illustrate imaging devices **1304** that may be used in conjunction with robot systems **100, 300, 600** to acquire pre-operative, intra-operative, post-operative, and/or real-time image data of patient **210**. Any appropriate subject matter may be imaged for any appropriate procedure using the imaging system **1304**. The imaging system **1304** may be any imaging device such as imaging device **1306** and/or a C-arm **1308** device. It may be desirable to take x-rays of patient **210** from a number of different positions, without the need for frequent manual repositioning of patient **210** which may be required in an x-ray system. As illustrated in FIG. 12A, the imaging system **1304** may be in the form of a C-arm **1308** that includes an elongated C-shaped member terminating in opposing distal ends **1312** of the "C" shape. C-shaped member **1130** may further comprise an x-ray source **1314** and an image receptor **1316**. The space within C-arm **1308** of the arm may provide room for the physician to attend to the patient substantially free of interference from x-ray support structure **1318**. As illustrated in FIG. 12B, the imaging system may include imaging device **1306** having a gantry housing **1324** attached to a support structure imaging device support structure **1328**, such as a wheeled mobile cart **1330** with wheels **1332**, which may enclose an image capturing portion, not illustrated. The

image capturing portion may include an x-ray source and/or emission portion and an x-ray receiving and/or image receiving portion, which may be disposed about one hundred and eighty degrees from each other and mounted on a rotor (not illustrated) relative to a track of the image capturing portion. The image capturing portion may be operable to rotate three hundred and sixty degrees during image acquisition. The image capturing portion may rotate around a central point and/or axis, allowing image data of patient 210 to be acquired from multiple directions or in multiple planes. Although certain imaging systems 1304 are exemplified herein, it will be appreciated that any suitable imaging system may be selected by one of ordinary skill in the art.

[0097] Turning now to FIGS. 13A-13C, the surgical robot system 100, 300, 600 relies on accurate positioning of the end-effector 112, 602, surgical instruments 608, and/or the patient 210 (e.g., patient tracking device 116) relative to the desired surgical area. In the embodiments shown in FIGS. 13A-13C, the tracking markers 118, 804 are rigidly attached to a portion of the instrument 608 and/or end-effector 112.

[0098] FIG. 13A depicts part of the surgical robot system 100 with the robot 102 including base 106, robot arm 104, and end-effector 112. The other elements, not illustrated, such as the display, cameras, etc. may also be present as described herein. FIG. 13B depicts a close-up view of the end-effector 112 with guide tube 114 and a plurality of tracking markers 118 rigidly affixed to the end-effector 112. In this embodiment, the plurality of tracking markers 118 are attached to the guide tube 112. FIG. 13C depicts an instrument 608 (in this case, a probe 608A) with a plurality of tracking markers 804 rigidly affixed to the instrument 608. As described elsewhere herein, the instrument 608 could include any suitable surgical instrument, such as, but not limited to, guide wire, cannula, a retractor, a drill, a reamer, a screw driver, an insertion tool, a removal tool, or the like.

[0099] When tracking an instrument 608, end-effector 112, or other object to be tracked in 3D, an array of tracking markers 118, 804 may be rigidly attached to a portion of the tool 608 or end-effector 112. Preferably, the tracking markers 118, 804 are attached such that the markers 118, 804 are out of the way (e.g., not impeding the surgical operation, visibility, etc.). The markers 118, 804 may be affixed to the instrument 608, end-effector 112, or other object to be tracked, for example, with an array 612. Usually three or four markers 118, 804 are used with an array 612. The array 612 may include a linear section, a cross piece, and may be asymmetric such that the markers 118, 804 are at different relative positions and locations with respect to one another. For example, as shown in FIG. 13C, a probe 608A with a 4-marker tracking array 612 is shown, and FIG. 13B depicts the end-effector 112 with a different 4-marker tracking array 612.

[0100] In FIG. 13C, the tracking array 612 functions as the handle 620 of the probe 608A. Thus, the four markers 804 are attached to the handle 620 of the probe 608A, which is out of the way of the shaft 622 and tip 624. Stereophotogrammetric tracking of these four markers 804 allows the instrument 608 to be tracked as a rigid body and for the tracking system 100, 300, 600 to precisely determine the position of the tip 624 and the orientation of the shaft 622 while the probe 608A is moved around in front of tracking cameras 200, 326.

[0101] To enable automatic tracking of one or more tools 608, end-effector 112, or other object to be tracked in 3D (e.g., multiple rigid bodies), the markers 118, 804 on each tool 608, end-effector 112, or the like, are arranged asymmetrically with a known inter-marker spacing. The reason for asymmetric alignment is so that it is unambiguous which marker 118, 804 corresponds to a particular location on the rigid body and whether markers 118, 804 are being viewed from the front or back, i.e., mirrored. For example, if the markers 118, 804 were arranged in a square on the tool 608 or end-effector 112, it would be unclear to the system 100, 300, 600 which marker 118, 804 corresponded to which corner of the square. For example, for the probe 608A, it would be unclear which marker 804 was closest to the shaft 622. Thus, it would be unknown which way the shaft 622 was extending from the array 612. Accordingly, each array 612 and thus each tool 608, end-effector 112, or other object to be tracked should have a unique marker pattern to allow it to be distinguished from other tools 608 or other objects being tracked. Asymmetry and unique marker patterns allow the system 100, 300, 600 to detect individual markers 118, 804 then to check the marker spacing against a stored template to determine which tool 608, end effector 112, or other object they represent. Detected markers 118, 804 can then be sorted automatically and assigned to each tracked object in the correct order. Without this information, rigid body calculations could not then be performed to extract key geometric information, for example, such as tool tip 624 and alignment of the shaft 622, unless the user manually specified which detected marker 118, 804 corresponded to which position on each rigid body. These concepts are commonly known to those skilled in the methods of 3D optical tracking.

[0102] Turning now to FIGS. 14A-14D, an alternative version of an end-effector 912 with moveable tracking markers 918A-918D is shown. In FIG. 14A, an array with moveable tracking markers 918A-918D are shown in a first configuration, and in FIG. 14B the moveable tracking markers 918A-918D are shown in a second configuration, which is angled relative to the first configuration. FIG. 14C shows the template of the tracking markers 918A-918D, for example, as seen by the cameras 200, 326 in the first configuration of FIG. 14A; and FIG. 14D shows the template of tracking markers 918A-918D, for example, as seen by the cameras 200, 326 in the second configuration of FIG. 14B.

[0103] In this embodiment, 4-marker array tracking is contemplated wherein the markers 918A-918D are not all in fixed position relative to the rigid body and instead, one or more of the array markers 918A-918D can be adjusted, for example, during testing, to give updated information about the rigid body that is being tracked without disrupting the process for automatic detection and sorting of the tracked markers 918A-918D.

[0104] When tracking any tool, such as a guide tube 914 connected to the end effector 912 of a robot system 100, 300, 600, the tracking array's primary purpose is to update the position of the end effector 912 in the camera coordinate system. When using the rigid system, for example, as shown in FIG. 13B, the array 612 of reflective markers 118 rigidly extend from the guide tube 114. Because the tracking markers 118 are rigidly connected, knowledge of the marker locations in the camera coordinate system also provides exact location of the centerline, tip, and tail of the guide tube 114 in the camera coordinate system. Typically, information

about the position of the end effector 112 from such an array 612 and information about the location of a target trajectory from another tracked source are used to calculate the required moves that must be input for each axis of the robot 102 that will move the guide tube 114 into alignment with the trajectory and move the tip to a particular location along the trajectory vector.

[0105] Sometimes, the desired trajectory is in an awkward or unreachable location, but if the guide tube 114 could be swiveled, it could be reached. For example, a very steep trajectory pointing away from the base 106 of the robot 102 might be reachable if the guide tube 114 could be swiveled upward beyond the limit of the pitch (wrist up-down angle) axis, but might not be reachable if the guide tube 114 is attached parallel to the plate connecting it to the end of the wrist. To reach such a trajectory, the base 106 of the robot 102 might be moved or a different end effector 112 with a different guide tube attachment might be exchanged with the working end effector. Both of these solutions may be time consuming and cumbersome.

[0106] As best seen in FIGS. 14A and 14B, if the array 908 is configured such that one or more of the markers 918A-918D are not in a fixed position and instead, one or more of the markers 918A-918D can be adjusted, swiveled, pivoted, or moved, the robot 102 can provide updated information about the object being tracked without disrupting the detection and tracking process. For example, one of the markers 918A-918D may be fixed in position and the other markers 918A-918D may be moveable; two of the markers 918A-918D may be fixed in position and the other markers 918A-918D may be moveable; three of the markers 918A-918D may be fixed in position and the other marker 918A-918D may be moveable; or all of the markers 918A-918D may be moveable.

[0107] In the embodiment shown in FIGS. 14A and 14B, markers 918A, 918B are rigidly connected directly to a base 906 of the end-effector 912, and markers 918C, 918D are rigidly connected to the tube 914. Similar to array 612, array 908 may be provided to attach the markers 918A-918D to the end-effector 912, instrument 608, or other object to be tracked. In this case, however, the array 908 is comprised of a plurality of separate components. For example, markers 918A, 918B may be connected to the base 906 with a first array 908A, and markers 918C, 918D may be connected to the guide tube 914 with a second array 908B. Marker 918A may be affixed to a first end of the first array 908A and marker 918B may be separated a linear distance and affixed to a second end of the first array 908A. While first array 908 is substantially linear, second array 908B has a bent or V-shaped configuration, with respective root ends, connected to the guide tube 914, and diverging therefrom to distal ends in a V-shape with marker 918C at one distal end and marker 918D at the other distal end. Although specific configurations are exemplified herein, it will be appreciated that other asymmetric designs including different numbers and types of arrays 908A, 908B and different arrangements, numbers, and types of markers 918A-918D are contemplated.

[0108] The guide tube 914 may be moveable, swivelable, or pivotable relative to the base 906, for example, across a hinge 920 or other connector to the base 906. Thus, markers 918C, 918D are moveable such that when the guide tube 914 pivots, swivels, or moves, markers 918C, 918D also pivot, swivel, or move. As best seen in FIG. 14A, guide tube 914

has a longitudinal axis 916 which is aligned in a substantially normal or vertical orientation such that markers 918A-918D have a first configuration. Turning now to FIG. 14B, the guide tube 914 is pivoted, swiveled, or moved such that the longitudinal axis 916 is now angled relative to the vertical orientation such that markers 918A-918D have a second configuration, different from the first configuration.

[0109] In contrast to the embodiment described for FIGS. 14A-14D, if a swivel existed between the guide tube 914 and the arm 104 (e.g., the wrist attachment) with all four markers 918A-918D remaining attached rigidly to the guide tube 914 and this swivel was adjusted by the user, the robotic system 100, 300, 600 would not be able to automatically detect that the guide tube 914 orientation had changed. The robotic system 100, 300, 600 would track the positions of the marker array 908 and would calculate incorrect robot axis moves assuming the guide tube 914 was attached to the wrist (the robot arm 104) in the previous orientation. By keeping one or more markers 918A-918D (e.g., two markers 918C, 918D) rigidly on the tube 914 and one or more markers 918A-918D (e.g., two markers 918A, 918B) across the swivel, automatic detection of the new position becomes possible and correct robot moves are calculated based on the detection of a new tool or end-effector 112, 912 on the end of the robot arm 104.

[0110] One or more of the markers 918A-918D are configured to be moved, pivoted, swiveled, or the like according to any suitable means. For example, the markers 918A-918D may be moved by a hinge 920, such as a clamp, spring, lever, slide, toggle, or the like, or any other suitable mechanism for moving the markers 918A-918D individually or in combination, moving the arrays 908A, 908B individually or in combination, moving any portion of the end-effector 912 relative to another portion, or moving any portion of the tool 608 relative to another portion.

[0111] As shown in FIGS. 14A and 14B, the array 908 and guide tube 914 may become reconfigurable by simply loosening the clamp or hinge 920, moving part of the array 908A, 908B relative to the other part 908A, 908B, and retightening the hinge 920 such that the guide tube 914 is oriented in a different position. For example, two markers 918C, 918D may be rigidly interconnected with the tube 914 and two markers 918A, 918B may be rigidly interconnected across the hinge 920 to the base 906 of the end-effector 912 that attaches to the robot arm 104. The hinge 920 may be in the form of a clamp, such as a wing nut or the like, which can be loosened and retightened to allow the user to quickly switch between the first configuration (FIG. 14A) and the second configuration (FIG. 14B).

[0112] The cameras 200, 326 detect the markers 918A-918D, for example, in one of the templates identified in FIGS. 14C and 14D. If the array 908 is in the first configuration (FIG. 14A) and tracking cameras 200, 326 detect the markers 918A-918D, then the tracked markers match Array Template 1 as shown in FIG. 14C. If the array 908 is the second configuration (FIG. 14B) and tracking cameras 200, 326 detect the same markers 918A-918D, then the tracked markers match Array Template 2 as shown in FIG. 14D. Array Template 1 and Array Template 2 are recognized by the system 100, 300, 600 as two distinct tools, each with its own uniquely defined spatial relationship between guide tube 914, markers 918A-918D, and robot attachment. The user could therefore adjust the position of the end-effector 912 between the first and second configurations without

notifying the system **100, 300, 600** of the change and the system **100, 300, 600** would appropriately adjust the movements of the robot **102** to stay on trajectory.

[0113] In this embodiment, there are two assembly positions in which the marker array matches unique templates that allow the system **100, 300, 600** to recognize the assembly as two different tools or two different end effectors. In any position of the swivel between or outside of these two positions (namely, Array Template 1 and Array Template 2 shown in FIGS. 14C and 14D, respectively), the markers **918A-918D** would not match any template and the system **100, 300, 600** would not detect any array present despite individual markers **918A-918D** being detected by cameras **200, 326**, with the result being the same as if the markers **918A-918D** were temporarily blocked from view of the cameras **200, 326**. It will be appreciated that other array templates may exist for other configurations, for example, identifying different instruments **608** or other end-effectors **112, 912**, etc.

[0114] In the embodiment described, two discrete assembly positions are shown in FIGS. 14A and 14B. It will be appreciated, however, that there could be multiple discrete positions on a swivel joint, linear joint, combination of swivel and linear joints, pegboard, or other assembly where unique marker templates may be created by adjusting the position of one or more markers **918A-918D** of the array relative to the others, with each discrete position matching a particular template and defining a unique tool **608** or end-effector **112, 912** with different known attributes. In addition, although exemplified for end effector **912**, it will be appreciated that moveable and fixed markers **918A-918D** may be used with any suitable instrument **608** or other object to be tracked.

[0115] When using an external 3D tracking system **100, 300, 600** to track a full rigid body array of three or more markers attached to a robot's end effector **112** (for example, as depicted in FIGS. 13A and 13B), it is possible to directly track or to calculate the 3D position of every section of the robot **102** in the coordinate system of the cameras **200, 326**. The geometric orientations of joints relative to the tracker are known by design, and the linear or angular positions of joints are known from encoders for each motor of the robot **102**, fully defining the 3D positions of all of the moving parts from the end effector **112** to the base **116**. Similarly, if a tracker were mounted on the base **106** of the robot **102** (not shown), it is likewise possible to track or calculate the 3D position of every section of the robot **102** from base **106** to end effector **112** based on known joint geometry and joint positions from each motor's encoder.

[0116] In some situations, it may be desirable to track the positions of all segments of the robot **102** from fewer than three markers **118** rigidly attached to the end effector **112**. Specifically, if a tool **608** is introduced into the guide tube **114**, it may be desirable to track full rigid body motion of the robot **902** with only one additional marker **118** being tracked.

[0117] Turning now to FIGS. 15A-15E, an alternative version of an end-effector **1012** having only a single tracking marker **1018** is shown. End-effector **1012** may be similar to the other end-effectors described herein, and may include a guide tube **1014** extending along a longitudinal axis **1016**. A single tracking marker **1018**, similar to the other tracking markers described herein, may be rigidly affixed to the guide tube **1014**. This single marker **1018** can serve the purpose of

adding missing degrees of freedom to allow full rigid body tracking and/or can serve the purpose of acting as a surveillance marker to ensure that assumptions about robot and camera positioning are valid.

[0118] The single tracking marker **1018** may be attached to the robotic end effector **1012** as a rigid extension to the end effector **1012** that protrudes in any convenient direction and does not obstruct the surgeon's view. The tracking marker **1018** may be affixed to the guide tube **1014** or any other suitable location on the end-effector **1012**. When affixed to the guide tube **1014**, the tracking marker **1018** may be positioned at a location between first and second ends of the guide tube **1014**. For example, in FIG. 15A, the single tracking marker **1018** is shown as a reflective sphere mounted on the end of a narrow shaft **1017** that extends forward from the guide tube **1014** and is positioned longitudinally above a mid-point of the guide tube **1014** and below the entry of the guide tube **1014**. This position allows the marker **1018** to be generally visible by cameras **200, 326** but also would not obstruct vision of the surgeon **120** or collide with other tools or objects in the vicinity of surgery. In addition, the guide tube **1014** with the marker **1018** in this position is designed for the marker array on any tool **608** introduced into the guide tube **1014** to be visible at the same time as the single marker **1018** on the guide tube **1014** is visible.

[0119] As shown in FIG. 15B, when a snugly fitting tool or instrument **608** is placed within the guide tube **1014**, the instrument **608** becomes mechanically constrained in 4 of 6 degrees of freedom. That is, the instrument **608** cannot be rotated in any direction except about the longitudinal axis **1016** of the guide tube **1014** and the instrument **608** cannot be translated in any direction except along the longitudinal axis **1016** of the guide tube **1014**. In other words, the instrument **608** can only be translated along and rotated about the centerline of the guide tube **1014**. If two more parameters are known, such as (1) an angle of rotation about the longitudinal axis **1016** of the guide tube **1014**; and (2) a position along the guide tube **1014**, then the position of the end effector **1012** in the camera coordinate system becomes fully defined.

[0120] Referring now to FIG. 15C, the system **100, 300, 600** should be able to know when a tool **608** is actually positioned inside of the guide tube **1014** and is not instead outside of the guide tube **1014** and just somewhere in view of the cameras **200, 326**. The tool **608** has a longitudinal axis or centerline **616** and an array **612** with a plurality of tracked markers **804**. The rigid body calculations may be used to determine where the centerline **616** of the tool **608** is located in the camera coordinate system based on the tracked position of the array **612** on the tool **608**.

[0121] The fixed normal (perpendicular) distance **D_F** from the single marker **1018** to the centerline or longitudinal axis **1016** of the guide tube **1014** is fixed and is known geometrically, and the position of the single marker **1018** can be tracked. Therefore, when a detected distance **D_p** from tool centerline **616** to single marker **1018** matches the known fixed distance **D_F** from the guide tube centerline **1016** to the single marker **1018**, it can be determined that the tool **608** is either within the guide tube **1014** (centerlines **616, 1016** of tool **608** and guide tube **1014** coincident) or happens to be at some point in the locus of possible positions where this distance **D_p** matches the fixed distance **D_F**. For example, in FIG. 15C, the normal detected distance **D_D** from tool

centerline **616** to the single marker **1018** matches the fixed distance **DF** from guide tube centerline **1016** to the single marker **1018** in both frames of data (tracked marker coordinates) represented by the transparent tool **608** in two positions, and thus, additional considerations may be needed to determine when the tool **608** is located in the guide tube **1014**.

[0122] Turning now to FIG. 15D, programmed logic can be used to look for frames of tracking data in which the detected distance **DD** from tool centerline **616** to single marker **1018** remains fixed at the correct length despite the tool **608** moving in space by more than some minimum distance relative to the single sphere **1018** to satisfy the condition that the tool **608** is moving within the guide tube **1014**. For example, a first frame **F1** may be detected with the tool **608** in a first position and a second frame **F2** may be detected with the tool **608** in a second position (namely, moved linearly with respect to the first position). The markers **804** on the tool array **612** may move by more than a given amount (e.g., more than 5 mm total) from the first frame **F1** to the second frame **F2**. Even with this movement, the detected distance **DD** from the tool centerline vector **C'** to the single marker **1018** is substantially identical in both the first frame **F1** and the second frame **F2**.

[0123] Logistically, the surgeon **120** or user could place the tool **608** within the guide tube **1014** and slightly rotate it or slide it down into the guide tube **1014** and the system **100, 300, 600** would be able to detect that the tool **608** is within the guide tube **1014** from tracking of the five markers (four markers **804** on tool **608** plus single marker **1018** on guide tube **1014**). Knowing that the tool **608** is within the guide tube **1014**, all 6 degrees of freedom may be calculated that define the position and orientation of the robotic end effector **1012** in space. Without the single marker **1018**, even if it is known with certainty that the tool **608** is within the guide tube **1014**, it is unknown where the guide tube **1014** is located along the tool's centerline vector **C'** and how the guide tube **1014** is rotated relative to the centerline vector **C'**.

[0124] With emphasis on FIG. 15E, the presence of the single marker **1018** being tracked as well as the four markers **804** on the tool **608**, it is possible to construct the centerline vector **C'** of the guide tube **1014** and tool **608** and the normal vector through the single marker **1018** and through the centerline vector **C'**. This normal vector has an orientation that is in a known orientation relative to the forearm of the robot distal to the wrist (in this example, oriented parallel to that segment) and intersects the centerline vector **C'** at a specific fixed position. For convenience, three mutually orthogonal vectors **k', j', i'** can be constructed, as shown in FIG. 15E, defining rigid body position and orientation of the guide tube **1014**. One of the three mutually orthogonal vectors **k'** is constructed from the centerline vector **C'**, the second vector **j'** is constructed from the normal vector through the single marker **1018**, and the third vector **i'** is the vector cross product of the first and second vectors **k', j'**. The robot's joint positions relative to these vectors **k', j', i'** are known and fixed when all joints are at zero, and therefore rigid body calculations can be used to determine the location of any section of the robot relative to these vectors **k', j', i'** when the robot is at a home position. During robot movement, if the positions of the tool markers **804** (while the tool **608** is in the guide tube **1014**) and the position of the single marker **1018** are detected from the tracking system, and

angles/linear positions of each joint are known from encoders, then position and orientation of any section of the robot can be determined.

[0125] In some embodiments, it may be useful to fix the orientation of the tool **608** relative to the guide tube **1014**. For example, the end effector guide tube **1014** may be oriented in a particular position about its axis **1016** to allow machining or implant positioning. Although the orientation of anything attached to the tool **608** inserted into the guide tube **1014** is known from the tracked markers **804** on the tool **608**, the rotational orientation of the guide tube **1014** itself in the camera coordinate system is unknown without the additional tracking marker **1018** (or multiple tracking markers in other embodiments) on the guide tube **1014**. This marker **1018** provides essentially a "clock position" from -180° to $+180^\circ$ based on the orientation of the marker **1018** relative to the centerline vector **C'**. Thus, the single marker **1018** can provide additional degrees of freedom to allow full rigid body tracking and/or can act as a surveillance marker to ensure that assumptions about the robot and camera positioning are valid.

[0126] FIG. 16 is a block diagram of a method **1100** for navigating and moving the end-effector **1012** (or any other end-effector described herein) of the robot **102** to a desired target trajectory. Another use of the single marker **1018** on the robotic end effector **1012** or guide tube **1014** is as part of the method **1100** enabling the automated safe movement of the robot **102** without a full tracking array attached to the robot **102**. This method **1100** functions when the tracking cameras **200, 326** do not move relative to the robot **102** (i.e., they are in a fixed position), the tracking system's coordinate system and robot's coordinate system are co-registered, and the robot **102** is calibrated such that the position and orientation of the guide tube **1014** can be accurately determined in the robot's Cartesian coordinate system based only on the encoded positions of each robotic axis.

[0127] For this method **1100**, the coordinate systems of the tracker and the robot must be co-registered, meaning that the coordinate transformation from the tracking system's Cartesian coordinate system to the robot's Cartesian coordinate system is needed. For convenience, this coordinate transformation can be a 4×4 matrix of translations and rotations that is well known in the field of robotics. This transformation will be termed **Tcr** to refer to "transformation-camera to robot". Once this transformation is known, any new frame of tracking data, which is received as x,y,z coordinates in vector form for each tracked marker, can be multiplied by the 4×4 matrix and the resulting x,y,z coordinates will be in the robot's coordinate system. To obtain **Tcr**, a full tracking array on the robot is tracked while it is rigidly attached to the robot at a location that is known in the robot's coordinate system, then known rigid body methods are used to calculate the transformation of coordinates. It should be evident that any tool **608** inserted into the guide tube **1014** of the robot **102** can provide the same rigid body information as a rigidly attached array when the additional marker **1018** is also read. That is, the tool **608** need only be inserted to any position within the guide tube **1014** and at any rotation within the guide tube **1014**, not to a fixed position and orientation. Thus, it is possible to determine **Tcr** by inserting any tool **608** with a tracking array **612** into the guide tube **1014** and reading the tool's array **612** plus the single marker **1018** of the guide tube **1014** while at the same time determining from

the encoders on each axis the current location of the guide tube **1014** in the robot's coordinate system.

[0128] Logic for navigating and moving the robot **102** to a target trajectory is provided in the method **1100** of FIG. 16. Before entering the loop **1102**, it is assumed that the transformation Tcr was previously stored. Thus, before entering loop **1102**, in step **1104**, after the robot base **106** is secured, greater than or equal to one frame of tracking data of a tool inserted in the guide tube while the robot is static is stored; and in step **1106**, the transformation of robot guide tube position from camera coordinates to robot coordinates Ter is calculated from this static data and previous calibration data. Tcr should remain valid as long as the cameras **200, 326** do not move relative to the robot **102**. If the cameras **200, 326** move relative to the robot **102**, and Ter needs to be re-obtained, the system **100, 300, 600** can be made to prompt the user to insert a tool **608** into the guide tube **1014** and then automatically perform the necessary calculations.

[0129] In the flowchart of method **1100**, each frame of data collected consists of the tracked position of the DRB **1404** on the patient **210**, the tracked position of the single marker **1018** on the end effector **1014**, and a snapshot of the positions of each robotic axis. From the positions of the robot's axes, the location of the single marker **1018** on the end effector **1012** is calculated. This calculated position is compared to the actual position of the marker **1018** as recorded from the tracking system. If the values agree, it can be assured that the robot **102** is in a known location. The transformation Ter is applied to the tracked position of the DRB **1404** so that the target for the robot **102** can be provided in terms of the robot's coordinate system. The robot **102** can then be commanded to move to reach the target.

[0130] After steps **1104, 1106**, loop **1102** includes step **1108** receiving rigid body information for DRB **1404** from the tracking system; step **1110** transforming target tip and trajectory from image coordinates to tracking system coordinates; and step **1112** transforming target tip and trajectory from camera coordinates to robot coordinates (apply Tcr). Loop **1102** further includes step **1114** receiving a single stray marker position for robot from tracking system; and step **1116** transforming the single stray marker from tracking system coordinates to robot coordinates (apply stored Tcr). Loop **1102** also includes step **1118** determining current location of the single robot marker **1018** in the robot coordinate system from forward kinematics. The information from steps **1116** and **1118** is used to determine step **1120** whether the stray marker coordinates from transformed tracked position agree with the calculated coordinates being less than a given tolerance. If yes, proceed to step **1122**, calculate and apply robot move to target x, y, z and trajectory. If no, proceed to step **1124**, halt and require full array insertion into guide tube **1014** before proceeding; step **1126** after array is inserted, recalculate Tcr; and then proceed to repeat steps **1108, 1114**, and **1118**.

[0131] This method **1100** has advantages over a method in which the continuous monitoring of the single marker **1018** to verify the location is omitted. Without the single marker **1018**, it would still be possible to determine the position of the end effector **1012** using Ter and to send the end-effector **1012** to a target location but it would not be possible to verify that the robot **102** was actually in the expected location. For example, if the cameras **200, 326** had been bumped and Tcr was no longer valid, the robot **102** would

move to an erroneous location. For this reason, the single marker **1018** provides value with regard to safety.

[0132] For a given fixed position of the robot **102**, it is theoretically possible to move the tracking cameras **200, 326** to a new location in which the single tracked marker **1018** remains unmoved since it is a single point, not an array. In such a case, the system **100, 300, 600** would not detect any error since there would be agreement in the calculated and tracked locations of the single marker **1018**. However, once the robot's axes caused the guide tube **1012** to move to a new location, the calculated and tracked positions would disagree and the safety check would be effective.

[0133] The term "surveillance marker" may be used, for example, in reference to a single marker that is in a fixed location relative to the DRB **1404**. In this instance, if the DRB **1404** is bumped or otherwise dislodged, the relative location of the surveillance marker changes and the surgeon **120** can be alerted that there may be a problem with navigation. Similarly, in the embodiments described herein, with a single marker **1018** on the robot's guide tube **1014**, the system **100, 300, 600** can continuously check whether the cameras **200, 326** have moved relative to the robot **102**. If registration of the tracking system's coordinate system to the robot's coordinate system is lost, such as by cameras **200, 326** being bumped or malfunctioning or by the robot malfunctioning, the system **100, 300, 600** can alert the user and corrections can be made. Thus, this single marker **1018** can also be thought of as a surveillance marker for the robot **102**.

[0134] It should be clear that with a full array permanently mounted on the robot **102** (e.g., the plurality of tracking markers **702** on end-effector **602** shown in FIGS. 7A-7C) such functionality of a single marker **1018** as a robot surveillance marker is not needed because it is not required that the cameras **200, 326** be in a fixed position relative to the robot **102**, and Ter is updated at each frame based on the tracked position of the robot **102**. Reasons to use a single marker **1018** instead of a full array are that the full array is more bulky and obtrusive, thereby blocking the surgeon's view and access to the surgical field **208** more than a single marker **1018**, and line of sight to a full array is more easily blocked than line of sight to a single marker **1018**.

[0135] Turning now to FIGS. 17A-17B and 18A-18B, instruments **608**, such as implant holders **608B, 608C**, are depicted which include both fixed and moveable tracking markers **804, 806**. The implant holders **608B, 608C** may have a handle **620** and an outer shaft **622** extending from the handle **620**. The shaft **622** may be positioned substantially perpendicular to the handle **620**, as shown, or in any other suitable orientation. An inner shaft **626** may extend through the outer shaft **622** with a knob **628** at one end. Implant **10, 12** connects to the shaft **622**, at the other end, at tip **624** of the implant holder **608B, 608C** using typical connection mechanisms known to those of skill in the art. The knob **628** may be rotated, for example, to expand or articulate the implant **10, 12**. U.S. Pat. Nos. 8,709,086 and 8,491,659, which are incorporated by reference herein, describe expandable fusion devices and methods of installation.

[0136] When tracking the tool **608**, such as implant holder **608B, 608C**, the tracking array **612** may contain a combination of fixed markers **804** and one or more moveable markers **806** which make up the array **612** or is otherwise attached to the implant holder **608B, 608C**. The navigation array **612** may include at least one or more (e.g., at least two)

fixed position markers **804**, which are positioned with a known location relative to the implant holder instrument **608B, 608C**. These fixed markers **804** would not be able to move in any orientation relative to the instrument geometry and would be useful in defining where the instrument **608** is in space. In addition, at least one marker **806** is present which can be attached to the array **612** or the instrument itself which is capable of moving within a pre-determined boundary (e.g., sliding, rotating, etc.) relative to the fixed markers **804**. The system **100, 300, 600** (e.g., the software) correlates the position of the moveable marker **806** to a particular position, orientation, or other attribute of the implant **10** (such as height of an expandable interbody spacer shown in FIGS. 17A-17B or angle of an articulating interbody spacer shown in FIGS. 18A-18B). Thus, the system and/or the user can determine the height or angle of the implant **10, 12** based on the location of the moveable marker **806**.

[0137] In the embodiment shown in FIGS. 17A-17B, four fixed markers **804** are used to define the implant holder **608B** and a fifth moveable marker **806** is able to slide within a pre-determined path to provide feedback on the implant height (e.g., a contracted position or an expanded position). FIG. 17A shows the expandable spacer **10** at its initial height, and FIG. 17B shows the spacer **10** in the expanded state with the moveable marker **806** translated to a different position. In this case, the moveable marker **806** moves closer to the fixed markers **804** when the implant **10** is expanded, although it is contemplated that this movement may be reversed or otherwise different. The amount of linear translation of the marker **806** would correspond to the height of the implant **10**. Although only two positions are shown, it would be possible to have this as a continuous function whereby any given expansion height could be correlated to a specific position of the moveable marker **806**.

[0138] Turning now to FIGS. 18A-18B, four fixed markers **804** are used to define the implant holder **608C** and a fifth, moveable marker **806** is configured to slide within a pre-determined path to provide feedback on the implant articulation angle. FIG. 18A shows the articulating spacer **12** at its initial linear state, and FIG. 18B shows the spacer **12** in an articulated state at some offset angle with the moveable marker **806** translated to a different position. The amount of linear translation of the marker **806** would correspond to the articulation angle of the implant **12**. Although only two positions are shown, it would be possible to have this as a continuous function whereby any given articulation angle could be correlated to a specific position of the moveable marker **806**.

[0139] In these embodiments, the moveable marker **806** slides continuously to provide feedback about an attribute of the implant **10, 12** based on position. It is also contemplated that there may be discreet positions that the moveable marker **806** must be in which would also be able to provide further information about an implant attribute. In this case, each discreet configuration of all markers **804, 806** correlates to a specific geometry of the implant holder **608B, 608C** and the implant **10, 12** in a specific orientation or at a specific height. In addition, any motion of the moveable marker **806** could be used for other variable attributes of any other type of navigated implant.

[0140] Although depicted and described with respect to linear movement of the moveable marker **806**, the moveable marker **806** should not be limited to just sliding as there may

be applications where rotation of the marker **806** or other movements could be useful to provide information about the implant **10, 12**. Any relative change in position between the set of fixed markers **804** and the moveable marker **806** could be relevant information for the implant **10, 12** or other device. In addition, although expandable and articulating implants **10, 12** are exemplified, the instrument **608** could work with other medical devices and materials, such as spacers, cages, plates, fasteners, nails, screws, rods, pins, wire structures, sutures, anchor clips, staples, stents, bone grafts, biologics, or the like.

[0141] One aspect of the present invention related to determining the 3-dimensional position of an imaging arm of an imaging device for taking optimal images of a vertebral body will now be explained with reference to FIGS. 19-27.

[0142] Most conventional systems do not have navigation capabilities and rely on users to position the C-arm. A few systems may have some navigation functions that allow a user to return to the previously stored position. In other words, existing systems may have the capability to let the user know where the imaging system may have been in the past. By contrast, the present invention as described with FIGS. 19-27 proposes to let the user know where the imaging system will need to be in the future to take optimal images.

[0143] FIG. 23 is an example of an x-ray imaging device **2300** having an automatic positioning capability with respect to the 3D position and orientation of its C-arm **2316** according to one aspect of the present invention. The imaging device **2300** includes a detector panel assembly **2314** containing a sensor array (not shown) for receiving x-ray transmission from an x-ray source **2312**. The imaging device **2300** is more fully described in U.S. Pat. No. 1,044,8910 assigned to the applicant of the present invention, which is incorporated herein by reference. The imaging device **2300** is capable of communicating with the surgical robot system **300** through the connector panel **320** by a physical I/O cable or wirelessly through well-known wireless transmission methods including WiFi, Bluetooth and the like.

[0144] Unlike the imaging system **2300**, which does not require a calibration ring, manually operated C-arms such as **1308** typically will have a calibration ring **2200** mounted to the detector panel assembly **1316** as shown in FIG. 12A. The calibration ring **2200** includes two spaced apart rings **2210, 2212**, each with a planar surface. Each planar surface contains a plurality of radiopaque markers **2206, 2208** that are spaced apart from each other in a selected pattern. Two sets of a plurality of circumferentially spaced optical markers **2202, 2204** are also mounted to the rings **2210, 2212**. The radiopaque markers **2206, 2208** are used to perform an initial registration of the imaging device **1308** (i.e., mapping of the C-arm position and orientation relative to the patient from the imaging space to the camera coordinate system) so that the tracking subsystem **532** can track the position and orientation of the C-arm **1308** during the surgical procedure. For an automatically navigated imaging system **2300**, a calibration ring is unnecessary and tracking and navigation of the system can be done with optical markers **2310** or the encoders that are positioned in every moving part of the system. The encoders can be used to mark the relative location and orientation of the C-arm **2316** at any time in use.

[0145] Once initial registration has been performed, the cameras 326 of the tracking subsystem 532 can continuously track the C-arm 2316 position and orientation through the optical markers 2202, 2204, and optionally through the markers 2310 on the C-arm 2316 during the surgical procedure.

[0146] FIG. 21 illustrates a flowchart of a method of determining the 3-dimensional (3D) position and orientation of an imaging device for each vertebral level for taking optimal AP and lateral images so that only one set of images are needed. The processing steps in FIG. 21 can be performed by an image control module 409 in the computer 408, processor of the imaging device 2300 itself, other remotely located processors or a combination thereof. In one embodiment, the image control module 409 includes computer executable code stored in a memory 410.

[0147] In step 2100, a user (typically an x-ray technician in the operating room) positions the imaging device 2300 around a patient table (not shown) such that the patient lying on the table is positioned inside the C-arm 2316. Once the imaging device 2300 is positioned, a pair of x-ray images (one AP image and one lateral image) are taken by the user without regard to how accurately or optimally the C-arm 2316 is positioned so long as the vertebral levels of interest are included. A typical AP image 2602 and lateral image 2604 are shown in FIG. 26. Once the two images are taken, they are received and stored by the computer 408.

[0148] Along with the images, the computer 408 also receives and stores the 3D position and orientation of the C-arm (e.g., 3D position and orientation of the imaging panel/intensifier or x-ray source of the C-arm, or both) for each of the two images 2602, 2604.

[0149] In step 2102, the vertebral bodies of interest are segmented for later analysis. Segmentation is a process by which certain points or features on a body part such as a vertebral body are identified. It can be manual, semi-automatic or fully automatic. An illustration of segmented vertebral bodies is shown in FIG. 26. The semi-automatic or fully automatic segmentation methods for identifying the relevant points of the vertebral body are well-known in the art. For example, an open-source software program called “ITK-SNAP” (available at www.itksnap.net) may allow the user to interactively segment out each vertebral body.

[0150] Step 2102 may also identify the vertebral levels as part of the segmentation process. This identification process can be totally manual, which requires a user to identify each level. Alternatively, the identification process can also be semi-automatic or fully automatic. In a semi-automatic case, the user may identify at least one level and the remaining levels are automatically applied based on image processing. For example, once the user identifies one vertebral body as being L4 (as shown in FIG. 26), the computer 408 automatically identifies all other levels based on the lordotic angle of the segmented bodies, for example. As a double check, the computer 408 may ask the user to confirm that the automatically identified levels, either by semi-automatic or fully automatic process, are correct.

[0151] In step 2104, the computer 408 asks the user to identify which vertebral levels are of interest. The user then identifies them using a graphical user interface, for example by touching the displayed levels on a touch screen display device 304 (e.g., four levels from L1 to LA).

[0152] In step 2106, the computer 408 retrieves from a database a 3D model 2702 of the spine including the

vertebral bodies of interest. The 3D model may be based on a statistical model which is not specific to any patient as most spines generally follow a standard pattern or it could be based on a specific patient in question from a 3D scan. Alternatively, the standard 3D model can be enhanced by patient specific data such as the lordotic and kyphotic angles which are derived from the images 2602, 2604. The retrieved vertebral bodies 2702 are then scaled so that the size of the bodies are the same as those in the AP and lateral images. The scaling may be based on the segmentation information obtained from step 2102.

[0153] In step 2106, for each vertebral body of interest, the computer 408 performs an alignment of the retrieved 3D model of a selected vertebral body to the corresponding segmented vertebral body in the AP and lateral images 2602, 2604. One method that may be used is a “fluoro-CT merge”, for example. One algorithm for the fluoro-CT merge can be found in an article entitled “Image-Assisted Navigation System for Spinal Surgery”, Applied Bionics and Biomechanics, Volume 2015, Article ID 478062, 9 pages, published May 28, 2015 (downloaded from <http://dx.doi.org/10.1155/2015/478062>), which is incorporated herein by reference. Essentially, the 3D vertebral model’s position and orientation (including X, Y, Z, Yaw, Roll and Pitch) is adjusted by the computer 408 until an optimum alignment is achieved.

[0154] FIGS. 27A and 27B graphically illustrate the alignment method. FIG. 27B illustrates the lateral test image 2710 from an x-ray source 2708. The lateral test image 2710 and x-ray source 2706 respectively correspond to the detector panel 2710 in the detector panel assembly 2314 and x-ray source 2312 of the imaging device 2300 at the time the test image was taken. The AP test image 2710 and x-ray source 2706 respectively correspond to the detector panel 2710 and x-ray source 2312 of the imaging device 2300 at the time the test image was taken. As can be seen, the model vertebral body 2702 is scaled and manipulated until the body matches most closely aligns with the corresponding vertebral body in the AP and lateral images.

[0155] Step 2106 is repeated for each vertebral body of interest as identified in step 2104.

[0156] Then, in step 2110, based on the optimal 3D position and orientation of the vertebral body as determined in step 2108, the computer 408 determines the optimal C-arm 2316 orientation and position (e.g., 3D position and orientation of either the detector panel 2314 or the x-ray source 2312, or both) so as to center the vertebral body with perfect AP and lateral angles. Then, the determined optimal C-arm 2316 orientation and position for the vertebral body are stored in the memory 410.

[0157] This optimal C-arm 2316 orientation and position determination of step 2110 can be partially seen in FIG. 27A. FIG. 27A shows the model vertebral body 2702 which has been aligned with the corresponding vertebral body in the AP and lateral test images 2602, 2604. As can be readily seen from the left screen shot 2720 showing a test AP image 2602, an optimum position for the C-arm 2316 would include rotating it clockwise by about 15 degrees and moving it down by about half a vertebral level to center the vertebral body. From the right screen shot 2722 showing a lateral test image 2604, an optimum position for the C-arm 2316 would include rotating it counter-clockwise by about 10 degrees and to move it left by about half a vertebral level to center the vertebral body in the image.

[0158] The optimal C-arm **2316** orientation and position of the vertebral body are then stored in the memory. In one embodiment, the orientation and position information for taking one of the two images are stored. Then, taking the other image is just a matter of rotating the C-arm **2316** by 90 degrees. In an alternative embodiment, the orientation and position information for taking both AP and lateral images are stored. If there are any additional levels that have not been processed, then steps **2106-2110** may be repeated.

[0159] In step **2112**, the computer **408** displays the available vertebral levels for optimal imaging for user selection in the display device **304**, one example of which is illustrated in FIG. 24A. For each level, the display **304** displays two user input buttons **2402** and **2404**. These buttons are used to position the imaging system **2300** to the ideal or optimal imaging position. The positioning can be either manual or automatic, depending on the image equipment being used. Button **2402** is for taking an AP image and box **2404** is for taking a lateral image. The user can select the image to be taken by an input device such as a mouse, touchscreen or keyboard. In one embodiment, the user can make the selection by touching the input button through a touch-sensitive screen of the display device **304**.

[0160] In decision **2114**, the computer **408** determine whether the imaging device **2300** has an automatic positioning capability. The automatic positioning capability allows the computer **408** to send position and orientation commands to move and rotate the C-arm **2316** of the imaging device **2300** in an optimal 3D position and orientation as determined in step **2110**.

[0161] If the imaging device **2300** is determined to have such a capability, then control passes to step **2116**. In step **2116**, the computer **408** sends the optimal 3D position and orientation of the C-arm **2316** to the imaging device.

[0162] In one embodiment, the computer **408** sends an absolute position and orientation data to the imaging device **2300**. This is possible if the imaging device **2300** knows its exact position within the operating room. In another embodiment, the computer **408** sends movement instructions that incrementally moves and positions the C-arm **2316** step by step. The computer **408** knows the relative position of the C-arm **2316** from the initial registration of the imaging device **2300** to the patient. From the registration data and the optical markers **2310** on the gantry, the computer **408** can track the relative location and orientation of the C-arm **2316** relative to the patient. From the tracking data and while the markers are being tracked, the computer can issue a series of incremental positioning commands to the imaging device **2300** until optimal C-arm **2316** position and orientation are reached.

[0163] If the imaging device is determined not to have such an automatic positioning capability (such as imaging system **1304** of FIG. 12A) in step **2114**, then control passes to step **2118**. In step **2118**, the computer **408** graphically displays on the display device **304** an indication of the C-arm **1308** position relative to the optimal position, and lets the user move and orient the C-arm **1308**. As the C-arm **1308** is moved by the user, the graphical display on the display device **304** is continuously updated to show the user how close the C-arm **1308** is to its optimal position. The location of the C-arm **1308** can be tracked by the optical markers **2202,2204** on the calibration ring **2200** or some other trackable markers that are positioned on the C-arm. One example of the graphical display is illustrated in FIG. 25.

[0164] The left image displays an x-y-z coordinate of the C-arm **1308**. The dotted circle represents the optimal position of the C-arm **1308**. The center of the dotted circle represents the optimal X-Y position with the size of the dotted circle representing the optimal Z position. The solid circle represents the actual position of the C-arm **1308**. As the user moves the C-arm **1308**, the solid circle moves and changes its size to indicate its actual 3D (X-Y-Z) position relative to the optimal position.

[0165] The right image displays a Yaw-Pitch-Roll coordinate of the C-arm **1308**. The dotted circle represents the optimal orientation of the C-arm **1308**. The center of the dotted circle represents the optimal Yaw-Pitch position with the size of the dotted circle representing the optimal Roll position. The solid circle represents the actual position of the C-arm **1308** in terms of Yaw, Pitch and Roll. As the user moves the C-arm **1308**, the solid circle moves and changes its size to indicate its 3D orientation relative to the optimal position.

[0166] Once the solid circle on both coordinates have been aligned with the respective dotted circles, the imaging device **1304** is ready to take the appropriate image. For example, if L1-AP **2402** had been selected by the user, the imaging device **2300** takes the AP image. It can be done by actuating an appropriate button on the imaging device or instructions from the computer **408** can be sent to do so.

[0167] Alternatively, once a vertebral level is selected, the computer **408** can send instructions to the imaging device **2300** to take both the optimal AP and lateral images based on the stored optimal position and orientation that have been determined through steps **2102-2110**.

[0168] In one embodiment, for every image taken and stored by the imaging device **2300**, the computer **408** also stores in the memory **410** the image as well as the position and orientation information of the C-arm **2316**. That can be achieved either through the optical markers **2310** and **2202-2204**, or through the imaging device's internal positioning elements such as encoders in the motors controlling every axis and 3D position of the C-arm **2316**.

[0169] As the images are being taken, additional vertebral levels may become available in the newly acquired images. For example, as optimal L1 images are being taken, those images may contain new levels such as L4. In one aspect of the present invention, the computer **408** stores the newly acquired images (both AP and lateral) and their position and orientation in the memory **410** and then repeats steps **2102** through **2112** for the new vertebral level if the new level was identified in step **2104** as of interest.

[0170] In another aspect of the present invention, the computer **408** may refine the optimal 3D position and orientation data which have already been obtained. In the same example, the computer **408** may repeat steps **2102** through **2112** for L2 and L3 based on the newly acquired AP and lateral images. Since the images were taken based on the optimal 3D position and orientation data for L1, they may also contain a more optimally aligned levels for L2 and L3. Thus, the refined 3D and orientation positions for L2 and L3 will likely be even more accurate than before.

[0171] In step **2112**, in addition to input buttons **2402,2404** for the old levels (e.g., L1-L3), the computer **408** displays the graphical representation of input buttons **2410,2412** for the new level (e.g., AP and lateral for L4) on the display device **304**.

[0172] As can be appreciated, the method described above substantially reduces the setup time for positioning an x-ray imaging device in the operating room as only two fluoro shots (one set of AP and lateral images) are needed for each vertebral level, instead of requiring 10 or more. This advantageous feature yields many benefits including a substantial reduction in procedure time, substantial reduction in radiation exposure for the patient as well as the medical professionals, and reduced cost for the procedure due to less time being required for the procedures. Perhaps more importantly, because the present invention allows more optimal images to be taken, it allows the physician to place the implants more accurately, which leads to better patient outcome in many surgeries.

[0173] In another aspect of the present invention, a system and method for identifying and segmenting anatomical structures from cone beam CT images, rather than from a reconstructed 3-D volume data is disclosed.

[0174] Cone beam CT reconstruction is a known method for creating a 3-D image volume wherein 2-D x-ray shots or images taken from different known perspectives are combined together to form a 3-D volume. Typically, X-rays are shot on a robotic revolving platform (see imaging device 2300 in FIG. 23, for example), with individual shots taken at small angular increments. For example, an imaging mechanism of the imaging device 2300 could revolve an x-ray emitter 2312 and collector 2314 around the patient through 360°, taking one x-ray image at every one degree increment. Knowing the orientation at which each x-ray was taken, the cone beam reconstruction software can combine the information from the 360 individual 2-D x-ray projections into a 3-D volume. The process of reconstructing a volume from a collection of shots is computationally intensive and typically requires at least 20 seconds to complete even with modern computer processors. The reconstruction software also may require all the shots to be present before image processing can start. In other words, processing may need to wait until the 360° spin is complete.

[0175] According to one aspect of the invention, a method is contemplated to use a software on 2-D samples from the acquisition of a series of shots for purposes of segmentation. Combining segmentation statistics from multiple 2-D perspectives would provide fast and reliable auto segmentation of the 3-D volume by the time the spin of the imaging device 2300 is complete.

[0176] FIG. 28 shows a flowchart of the workflow when using the 2-D auto segmentation software, which is a part of the image control module 409. As discussed in relation to FIGS. 5 and 21, the image control module 409 is stored in the memory 410 of a computer subsystem 504 for a surgical robotic system. In addition to determining the 3-D position and orientation of an imaging device for each vertebral level as discussed with reference to FIG. 21, the image control software includes additional software that performs the segmentation steps of FIG. 28 as well as a 3-D volume reconstruction software for cone beam CT.

[0177] In step 2800, the image control module 409 starts the 3D spin of the cone beam CT imaging device 2300 which includes initialization of the x-ray transmitter, collector and other electronics. In step 2802, the image control module 409 controls the c-arm 2316 of the imaging device 2300 to move to the appropriate angular position and take an x-ray image. In case of a first image, the imaging device 2300 may move the c-arm 2316 to a zero degree offset

relative to a base of the device 2300 (e.g., perpendicular to the floor) to take that first image. The taken image is then transmitted to and stored in the memory 410. In subsequent imaging, the module 409 controls the c-arm 2316 to move to a predetermined angular position. For example, the c-arm 2316 may move by one degree.

[0178] Since the orientation of the c-arm 2316 can be tracked by the tracking subsystem 532 through the tracking markers 2310, the orientation data for each image taken is also recorded and transmitted to the memory 410 for storage.

[0179] In step 2804, the module 409 determines whether the image just taken in step 2802 should be analyzed for segmentation. For example, the module 409 determines whether the image is a multiple of N where N is an integer. In one embodiment, N is at least 5. If N=5, it means that every 5th image (5 degrees offset from the previous image) is to be analyzed.

[0180] While only a selected set of 2-D x-ray images is selected for processing to save time, it is possible for the module 409 to perform the segmentation step 2806 for every 2-D image from the c-arm 2316.

[0181] If the decision is Yes, control passes to step 2806. In step 2806, the module 409 executes an auto-segmentation method based on a previously stored model. The model could be enhanced or trained with deep learning or neural network for training computer models to recognize structures within an image plane by comparing the image to a set of known images. In case of a spine, the segmentation may include determining boundaries of each vertebral body, its center (x,y,z location of the center of the vertebral body), 3-D angular orientation of each body, and vertebral level for each body.

[0182] When the auto-segmentation is completed, the method may also generate a set of confidence factors which may include a confidence level for identification of vertebral levels, for center of each vertebral body in the image, and for 3-D angular orientation of each body.

[0183] With regard to the confidence factor for the vertebral levels, the confidence could reflect how certain the software is that the level for each vertebral body has been correctly determined. With regard to X, Y,Z coordinates of the center of the vertebral body, the confidence

[0184] could reflect how certain the center finding method is that the coordinates are the value found correctly within some tolerance (for example, 1 mm).

[0185] With regard to the unit vectors describing 3-D orientation, the confidence could reflect how certain the orientation finding method is that the orientation was found correctly within some tolerance (for example, 1 degree).

[0186] If the decision at step 2804 is No, then control passes to step 2808. In step 2808, the module 409 updates the display of the x-ray image with the segmentation and identification information obtained from step 2806. As the scan proceeds, the display device 304 may show information such as a progress bar and can also display the last 2-D shot on the screen, as well as adjusting and displaying the latest labels on the 2-D shots and in the region of the screen where the volume will appear.

[0187] In step 2810, it is determined whether the 3-D image spin is complete. In one embodiment, the spin is complete when all 360 images at one degree interval are taken. If the spin has not completed, then control returns to

step 2802 where the c-arm 2316 is incremented by the predetermined angular interval and the next x-ray image is taken.

[0188] If the decision in step 2810 is Yes, control passes to step 2811. In step 2811, the segmentation and identification for each image in step 2806 is refined by analyzing all of the data obtained from step 2806.

[0189] In one embodiment, a weighting scheme is used. For the vertebral level finding method, the data tabulation might show that the average certainty of identifying the top level is 85% L1, 75% L2, 75% L3, 75% L4, 70% L5, with each of those values taken as plain average for the 36 images. In such a case, the method would name the top level L1 because that is the best guess. There might be cases where there is not an obvious answer. For example, there could be a case where the average certainty score, considering all images, shows that the top level is named L1 and also shows that the next level down is named L1. In such a case, the method may look at the individual images going around and look at whether L1 certainty was separated by a larger margin at any one shot than all the other levels when considering the top vertebra compared to the next one down. For example, considering the first five 2-D x-ray images, assume that the top level had certainty scores as follows:

- [0190] 1) 85% L1, 75% L2, 74% L3, 76% L4, 70% L5
- [0191] 2) 85% L1, 76% L2, 75% L3, 75% L4, 69% L5
- [0192] 3) 86% L1, 75% L2, 76% L3, 75% L4, 70% L5
- [0193] 4) 85% L1, 74% L2, 75% L3, 75% L4, 70% L5
- [0194] 5) 84% L1, 75% L2, 75% L3, 74% L4, 71% L5

[0195] But further assume that the next level down had certainty scores as follows:

- [0196] 1) 95% L1, 45% L2, 45% L3, 45% L4, 45% L5
- [0197] 2) 83% L1, 80% L2, 85% L3, 82% L4, 76% L5
- [0198] 3) 80% L1, 88% L2, 83% L3, 84% L4, 76% L5
- [0199] 4) 84% L1, 74% L2, 84% L3, 82% L4, 76% L5
- [0200] 5) 83% L1, 88% L2, 78% L3, 82% L4, 77% L5

[0201] In both data sets, the averages of the 5 values would be the same. However, in the second data set, L1 had a large separation from the competing names at the first shot (95% L1 vs. 45% L2 or other=50% difference in certainty), whereas in the first case, the separation in certainty is small (9% to 11% difference in certainty that level name is L1 vs other name). Accordingly, the method may decide that the next level down is more likely L1 than the first level. Since it is known that the levels are numbered in order, wherein L1 is above L2, which is above L3, etc., the method might consider all the levels first and find the most likely overall level, then name the others according to where they fall geometrically.

[0202] However, for a center finding method, it may be unimportant what the vertebra's level is named, and weighting may be used differently. As the spin goes around, just focusing on the top vertebra (whatever that is named), the algorithm might find the center (XYZ) with the following certainties for the first 7 shots: 95%, 92%, 75%, 25%, 25%, 75%, 95%.

[0203] Rather than averaging in the X, Y,Z coordinates for the centers of the two shots with only 25% certainty (even considering weighting), the method could exclude those two values because they are below a selected threshold (e.g., 70%). The other 5 images that are kept could be averaged using weighting so their certainties are accounted for. The weighted average for these 5 remaining values would be

calculated using the common method: sum of (weight*value)/sum of weight.

[0204] After step 2811, control then passes to step 2812. In step 2812, the module 409 creates a 3-D image volume 2900 (see FIG. 29A) using a well-known cone beam reconstruction method by combining all of the 2-D x-ray images taken (e.g., 360 images at 1 degree increments) at different known angular orientations from the previous steps.

[0205] Subsequent to 3-D reconstruction, a conventional method would have involved an additional step of segmentation and identification using the just created 3-D volume which is computationally very intensive.

[0206] According to the principles of the present invention, however, the segmentation information has already been derived from the 2-D images in the previous steps. Thus, the segmentation and identification information are fed into step 2812 and overlaid on the 3-D image volume as shown in FIG. 29B, to result in a substantial time saving. As the cone beam spin takes place typically in an operating room, saving procedure time could be very important for both patient safety and procedure cost.

[0207] In step 2814, the updated 3-D image volume 2910 with the segmentation information is displayed on a display device 304 for manipulation by a physician. The segmentation information may include boundary points that delineate each vertebral body (see FIG. 26, for example), center position, and 3-D orientation of each body (2902-2908). The identification information may include the level of each vertebral body (L1-L4) and other bones or anatomical structures that may be visible in the scan volume.

[0208] The graphical user interface portion of the module 409 allows the physician to move the 3-D image volume 2900 with six degrees of freedom to assist the physician with planning the implants.

[0209] Persons of ordinary skill in the art will appreciate that although the present invention has been described with respect to vertebral bodies, the principles of the invention can apply to any other tissue structure in the body such as knee joint, ankle joint, fingers and the like.

[0210] Although several embodiments of the invention have been disclosed in the foregoing specification, it is understood that many modifications and other embodiments of the invention will come to mind to which the invention pertains, having the benefit of the teaching presented in the foregoing description and associated drawings. It is thus understood that the invention is not limited to the specific embodiments disclosed hereinabove, and that many modifications and other embodiments are intended to be included within the scope of the appended claims. It is further envisioned that features from one embodiment may be combined or used with the features from a different embodiment described herein. Moreover, although specific terms are employed herein, as well as in the claims which follow, they are used only in a generic and descriptive sense, and not for the purposes of limiting the described invention, nor the claims which follow. The entire disclosure of each patent and publication cited herein is incorporated by reference, as if each such patent or publication were individually incorporated by reference herein. Various features and advantages of the invention are set forth in the following claims.

What is claimed is:

1. A system of identifying and segmenting anatomical structures from cone beam CT images, the system comprising:

a cone beam CT device receiving at least one x-ray image, which is part of a plurality of x-ray images taken from a 360 degree scan of a patient, the at least one x-ray image containing at least one anatomical structure; a computer system for identifying and segmenting the at least one anatomical structure contained in the x-ray image based on a stored model of anatomical structures; and a 3-D image volume image generated from a plurality of x-ray images from the 360 degree scan; wherein the identification and segmentation information is derived from the at least one x-ray image to the created 3-D image volume wherein computer system is configured to determine a center of the at least one anatomical structure, wherein the computer system receives a set of x-ray images at regularly spaced angular orientations; and for each received x-ray image, a confidence level of a match for the each x-ray image is determined; optimal identification and segmentation information based on the confidence levels is determined, and wherein the computer system determines the center of the anatomical structure by weighting the x-ray images based on the confidence level.

2. The system of claim 1, wherein the system identifies and segments at least one vertebral body contained in the x-ray image.

3. The system of claim 1, wherein the system determines optimal identification and segmentation information which includes excluding the x-ray images that have a lower confidence level than a predetermined confidence level.

4. The system of claim 1, wherein the system receives every N-th x-ray image from the 360 degree scan in which N equals 5 or greater.

5. The system of claim 4, wherein the system receives each N-th x-ray image includes receiving the angular orientation information for the each N-th x-ray image.

6. The system of claim 1, wherein the system determines a confidence level which includes determining a confidence level of the center of the at least one anatomical structure.

7. A surgical imaging system for identifying and segmenting vertebral bodies from cone beam CT images, comprising:

a cone beam CT device configured to receive a set of x-ray images taken at different angular orientations, each image containing at least one vertebral body; for each received x-ray image, a computer having a processor identifies and segments the at least one vertebral body contained in the x-ray image based on a stored model of vertebral bodies; determines a confidence level of the identification and segmentation for the each x-ray image; determines optimal identification and segmentation information based on the confidence levels; determines a center of the at least one vertebral body; determines the center of the vertebral bodies by weighting the x-ray images based on the confidence level.

8. The system of claim 7, further comprising:
a 3-D image volume image generated from a plurality of x-ray images from the 360 degree scan, the plurality of x-ray images including the set of x-ray-images; adding the optimal identification and segmentation information to the created 3-D image volume image.

9. The system of claim 8, wherein the system identifies and segments information includes excluding the x-ray images that have a lower confidence level than a predetermined confidence level.

10. The system of claim 7, wherein the system receives every N-th x-ray image from the 360 degree scan in which N equals 5 or greater.

11. The system of claim 10, wherein the system receives each N-th x-ray image includes receiving the angular orientation information for the each N-th x-ray image.

12. The system of claim 7, further comprising:
a 3-D image volume generated from a plurality of x-ray images from the 360 degree scan, the plurality of x-ray images including the set of x-ray-images; wherein the system adds the optimal identification and segmentation information to the created 3-D image volume; and displays the 3-D image volume with the added identification and segmentation information for manipulation by a user.
