Determining a time to permit a communications session to be conducted

Abstract

A method, apparatus and system for routing a communication in a communication system between a first participant device, on an Internet Protocol (IP) network, associated with a first participant, and a second participant device associated with a second participant. The method comprises receiving a second participant identifier associated with the second participant device, causing the at least one processor to access a user profile that is specific to the first participant and associated with a plurality of first participant attributes, comparing the second participant and at least one first participant attribute and identifying whether at least one route exists, producing route information to an Internet Protocol (IP) address on a first communication network or associated with a gateway to the second communication network, and establishing the communication to the second participant. At least one of the networks may utilize Public Switched Telephone Network (PSTN) compatible numbers for identifying a route for the communication.

Inventors: Bjorsell; Johan Emil Viktor (Vancouver, CA)

Applicant: VoIP-Pal.com, Inc. (Bellevue, WA)

Family ID: 1000008762186

Assignee: VolP-Pal.com, Inc. (N/A, CA)

Appl. No.: 17/521836

Filed: November 08, 2021

Background/Summary

CROSS REFERENCE TO RELATED APPLICATIONS (1) This application is a continuation of U.S. patent application Ser. No. 14/853,705, filed Sep. 14, 2015, which is a continuation of U.S. patent application Ser. No. 14/029,671, filed Sep. 17, 2013, which is a continuation of U.S. patent application Ser. No. 12/513,147, filed Mar. 1, 2010, which is a national phase entry of International Application No. PCT/CA2007/001956, filed Nov. 1, 2007, which claims the benefit of U.S. Provisional Patent Application No. 60/856,212, filed on Nov. 2, 2006, all of which are incorporated herein by reference.

BACKGROUND OF THE INVENTION

Field of Invention

(1) This invention relates to voice over IP communications and methods and apparatus for routing and billing.

Description of Related Art

- (2) Internet protocol (IP) telephones are typically personal computer (PC) based telephones connected within an IP network, such as the public Internet or a private network of a large organization. These IP telephones have installed "voice-over-IP" (VoIP) software enabling them to make and receive voice calls and send and receive information in data and video formats.
- (3) IP telephony switches installed within the IP network enable voice calls to be made within or between IP networks, and between an IP network and a switched circuit network (SCN), such as the public switched telephone network (PSTN). If the IP switch supports the Signaling System 7 (SS7) protocol, the IP telephone can also access PSTN databases.
- (4) The PSTN network typically includes complex network nodes that contain all information about a local calling service area including user authentication and call routing. The PSTN network typically aggregates all information and traffic into a single location or node, processes it locally and then passes it on to other network nodes, as necessary, by maintaining route tables at the node. PSTN nodes are redundant by design and thus provide reliable service, but if a node should fail due

to an earthquake or other natural disaster, significant, if not complete service outages can occur, with no other nodes being able to take up the load.

(5) Existing VoIP systems do not allow for high availability and resiliency in delivering Voice Over IP based Session Initiation Protocol (SIP) Protocol service over a geographically dispersed area such as a city, region or continent. Most resiliency originates from the provision of IP based telephone services to one location or a small number of locations such as a single office or network of branch offices.

SUMMARY OF THE INVENTION

- (6) In accordance with one aspect of the invention, there is provided a process for operating a call routing controller to facilitate communication between callers and callees in a system comprising a plurality of nodes with which callers and callees are associated. The process involves, in response to initiation of a call by a calling subscriber, receiving a caller identifier and a callee identifier. The process also involves using call classification criteria associated with the caller identifier to classify the call as a public network call or a private network call. The process further involves producing a routing message identifying an address, on the private network, associated with the callee when the call is classified as a private network call. The process also involves producing a routing message identifying a gateway to the public network when the call is classified as a public network call.
- (7) The process may involve receiving a request to establish a call, from a call controller in communication with a caller identified by the callee identifier.
- (8) Using the call classification criteria may involve searching a database to locate a record identifying calling attributes associated with a caller identified by the caller identifier.
- (9) Locating a record may involve locating a caller dialing profile comprising a username associated with the caller, a domain associated with the caller, and at least one calling attribute.
- (10) Using the call classification criteria may involve comparing calling attributes associated with the caller dialing profile with aspects of the callee identifier.
- (11) Comparing may involve determining whether the callee identifier includes a portion that matches an IDD associated with the caller dialing profile.
- (12) Comparing may involve determining whether the callee identifier includes a portion that matches an NDD associated with the caller dialing profile.
- (13) Comparing may involve determining whether the callee identifier includes a portion that matches an area code associated with the caller dialing profile.
- (14) Comparing may involve determining whether the callee identifier has a length within a range specified in the caller dialing profile.
- (15) The process may involve formatting the callee identifier into a pre-defined digit format to produce a re-formatted callee identifier.
- (16) Formatting may involve removing an international dialing digit from the callee identifier, when the callee identifier begins with a digit matching an international dialing digit specified by the caller dialing profile associated with the caller.
- (17) Formatting may involve removing a national dialing digit from the callee identifier and prepending a caller country code to the callee identifier when the callee identifier begins with a national dialing digit.
- (18) Formatting may involve prepending a caller country code to the callee identifier when the callee identifier begins with digits identifying an area code specified by the caller dialing profile.
- (19) Formatting may involve prepending a caller country code and an area code to the callee identifier when the callee identifier has a length that matches a caller dialing number format specified by the caller dialing profile and only one area code is specified as being associated with the caller in the caller dialing profile.
- (20) The process may involve classifying the call as a private network call when the re-formatted callee identifier identifies a subscriber to the private network. The process may involve determining whether the callee identifier complies with a pre-defined username format and if so, classifying the

call as a private network call.

- (21) The process may involve causing a database of records to be searched to locate a direct in dial (DID) bank table record associating a public telephone number with the reformatted callee identifier and if the DID bank table record is found, classifying the call as a private network call and if a DID bank table record is not found, classifying the call as a public network call.
- (22) Producing the routing message identifying a node on the private network may involve setting a callee identifier in response to a username associated with the DID bank table record.
- (23) Producing the routing message may involve determining whether a node associated with the reformatted callee identifier is the same as a node associated the caller identifier.
- (24) Determining whether a node associated with the reformatted callee identifier is the same as a node associated the caller identifier may involve determining whether a prefix of the re-formatted callee identifier matches a corresponding prefix of a username associated with the caller dialing profile.
- (25) When the node associated with the caller is not the same as the node associated with the callee, the process involves producing a routing message including the caller identifier, the reformatted callee identifier and an identification of a private network node associated with the callee and communicating the routing message to a call controller.
- (26) When the node associated with the caller is the same as the node associated with the callee, the process involves determining whether to perform at least one of the following: forward the call to another party, block the call and direct the caller to a voicemail server associated with the callee.
- (27) Producing the routing message may involve producing a routing message having an identification of at least one of the callee identifier, an identification of a party to whom the call should be forwarded and an identification of a voicemail server associated with the callee.
- (28) The process may involve communicating the routing message to a call controller.
- (29) Producing a routing message identifying a gateway to the public network may involve searching a database of route records associating route identifiers with dialing codes to find a route record having a dialing code having a number pattern matching at least a portion of the reformatted callee identifier.
- (30) The process may involve searching a database of supplier records associating supplier identifiers with the route identifiers to locate at least one supplier record associated with the route identifier associated with the route record having a dialing code having a number pattern matching at least a portion of the reformatted callee identifier.
- (31) The process may involve loading a routing message buffer with the reformatted callee identifier and an identification of specific routes associated respective ones of the supplier records associated with the route record and loading the routing message buffer with a time value and a timeout value.
- (32) The process may involve communicating a routing message involving the contents of the routing message buffer to a call controller.
- (33) The process may involve causing the dialing profile to include a maximum concurrent call value and a concurrent call count value and causing the concurrent call count value to be incremented when the user associated with the dialing profile initiates a call and causing the concurrent call count value to be decremented when a call with the user associated with the dialing profile is ended.
- (34) In accordance with another aspect of the invention, there is provided a call routing apparatus for facilitating communications between callers and callees in a system comprising a plurality of nodes with which callers and callees are associated. The apparatus includes receiving provisions for receiving a caller identifier and a callee identifier, in response to initiation of a call by a calling subscriber. The apparatus also includes classifying provisions for classifying the call as a private network call or a public network call according to call classification criteria associated with the caller identifier. The apparatus further includes provisions for producing a routing message

identifying an address, on the private network, associated with the callee when the call is classified as a private network call. The apparatus also includes provisions for producing a routing message identifying a gateway to the public network when the call is classified as a public network call.

- (35) The receiving provisions may be operably configured to receive a request to establish a call, from a call controller in communication with a caller identified by the callee identifier.
- (36) The apparatus may further include searching provisions for searching a database including records associating calling attributes with subscribers to the private network to locate a record identifying calling attributes associated with a caller identified by the caller identifier.
- (37) The records may include dialing profiles each including a username associated with the subscriber, an identification of a domain associated with the subscriber, and an identification of at least one calling attribute associated with the sub scriber.
- (38) The call classification provisions may be operably configured to compare calling attributes associated with the caller dialing profile with aspects of the callee identifier.
- (39) The calling attributes may include an international dialing digit and call classification provisions may be operably configured to determine whether the callee identifier includes a portion that matches an IDD associated with the caller dialing profile.
- (40) The calling attributes may include an national dialing digit and the call classification provisions may be operably configured to determine whether the callee identifier includes a portion that matches an NDD associated with the caller dialing profile.
- (41) The calling attributes may include an area code and the call classification provisions may be operably configured to determine whether the callee identifier includes a portion that matches an area code associated with the caller dialing profile.
- (42) The calling attribute may include a number length range and the call classification provisions may be operably configured to determine whether the callee identifier has a length within a number length range specified in the caller dialing profile.
- (43) The apparatus may further include formatting provisions for formatting the callee identifier into a pre-defined digit format to produce a re-formatted callee identifier.
- (44) The formatting provisions may be operably configured to remove an international dialing digit from the callee identifier, when the callee identifier begins with a digit matching an international dialing digit specified by the caller dialing profile associated with the caller.
- (45) The formatting provisions may be operably configured to remove a national dialing digit from the callee identifier and prepend a caller country code to the callee identifier when the callee identifier begins with a national dialing digit.
- (46) The formatting provisions may be operably configured to prepend a caller country code to the callee identifier when the callee identifier begins with digits identifying an area code specified by the caller dialing profile.
- (47) The formatting provisions may be operably configured to prepend a caller country code and area code to the callee identifier when the callee identifier has a length that matches a caller dialing number format specified by the caller dialing profile and only one area code is specified as being associated with the caller in the caller dialing profile.
- (48) The classifying provisions may be operably configured to classify the call as a private network call when the re-formatted callee identifier identifies a subscriber to the private network.
- (49) The classifying provisions may be operably configured to classify the call as a private network call when the callee identifier complies with a pre-defined username format.
- (50) The apparatus may further include searching provisions for searching a database of records to locate a direct in dial (DID) bank table record associating a public telephone number with the reformatted callee identifier and the classifying provisions may be operably configured to classify the call as a private network call when the DID bank table record is found and to classify the call as a public network call when a DID bank table record is not found.
- (51) The private network routing message producing provisions may be operably configured to

produce a routing message having a callee identifier set according to a username associated with the DID bank table record.

- (52) The private network routing message producing provisions may be operably configured to determine whether a node associated with the reformatted callee identifier is the same as a node associated the caller identifier.
- (53) The private network routing provisions may include provisions for determining whether a prefix of the re-formatted callee identifier matches a corresponding prefix of a username associated with the caller dialing profile.
- (54) The private network routing message producing provisions may be operably configured to produce a routing message including the caller identifier, the reformatted callee identifier and an identification of a private network node associated with the callee and to communicate the routing message to a call controller.
- (55) The private network routing message producing provisions may be operably configured to perform at least one of the following forward the call to another party, block the call and direct the caller to a voicemail server associated with the callee, when the node associated with the caller is the same as the node associated with the callee.
- (56) The provisions for producing the private network routing message may be operably configured to produce a routing message having an identification of at least one of the callee identifier, an identification of a party to whom the call should be forwarded and an identification of a voicemail server associated with the callee.
- (57) The apparatus further includes provisions for communicating the routing message to a call controller.
- (58) The provisions for producing a public network routing message identifying a gateway to the public network may include provisions for searching a database of route records associating route identifiers with dialing codes to find a route record having a dialing code having a number pattern matching at least a portion of the reformatted callee identifier.
- (59) The apparatus further includes provisions for searching a database of supplier records associating supplier identifiers with the route identifiers to locate at least one supplier record associated with the route identifier associated with the route record having a dialing code having a number pattern matching at least a portion of the reformatted callee identifier.
- (60) The apparatus further includes a routing message buffer and provisions for loading the routing message buffer with the reformatted callee identifier and an identification of specific routes associated respective ones of the supplier records associated with the route record and loading the routing message buffer with a time value and a timeout value.
- (61) The apparatus further includes provisions for communicating a routing message including the contents of the routing message buffer to a call controller.
- (62) The apparatus further includes means for causing said dialing profile to include a maximum concurrent call value and a concurrent call count value and for causing said concurrent call count value to be incremented when the user associated with said dialing profile initiates a call and for causing said concurrent call count value to be decremented when a call with said user associated with said dialing profile is ended.
- (63) In accordance with another aspect of the invention, there is provided a data structure for access by an apparatus for producing a routing message for use by a call routing controller in a communications system. The data structure includes dialing profile records comprising fields for associating with respective subscribers to the system, a subscriber user name, direct-in-dial records comprising fields for associating with respective subscriber usernames, a user domain and a direct-in-dial number, prefix to node records comprising fields for associating with at least a portion of the respective subscriber usernames, a node address of a node in the system, whereby a subscriber name can be used to find a user domain, at least a portion of the a subscriber name can be used to find a node with which the subscriber identified by the subscriber name is associated, and a user

domain and subscriber name can be located in response to a direct-in-dial number.

- (64) In accordance with another aspect of the invention, there is provided a data structure for access by an apparatus for producing a routing message for use by a call routing controller in a communications system. The data structure includes master list records comprising fields for associating a dialing code with respective master list identifiers and supplier list records linked to master list records by the master list identifiers, said supplier list records comprising fields for associating with a communications services supplier, a supplier id, a master list id, a route identifier and a billing rate code, whereby communications services suppliers are associated with dialing codes, such that dialing codes can be used to locate suppliers capable of providing a communications link associated with a given dialing code.
- (65) In accordance with another aspect of the invention, there is provided a method for determining a time to permit a communication session to be conducted. The method involves calculating a cost per unit time, calculating a first time value as a sum of a free time attributed to a participant in the communication session and the quotient of a funds balance held by the participant to the cost per unit time value and producing a second time value in response to the first time value and a billing pattern associated with the participant, the billing pattern including first and second billing intervals and the second time value being the time to permit a communication session to be conducted.

 (66) Calculating the first time value may involve retrieving a record associated with the participant
- and obtaining from the record at least one of the free time and the funds balance.
- (67) Producing the second time value may involve producing a remainder value representing a portion of the second billing interval remaining after dividing the second billing interval into a difference between the first time value and the first billing interval.
- (68) Producing the second time value may involve setting a difference between the first time value and the remainder as the second time value.
- (69) The method may further involve setting the second time value to zero when the remainder is greater than zero and the first time value is less than the free time associated with the participant.
- (70) Calculating the cost per unit time may involve locating a record in a database, the record comprising a markup type indicator, a markup value and a billing pattern and setting a reseller rate equal to the sum of the markup value and the buffer rate.
- (71) Locating the record in a database may involve locating at least one of a record associated with a reseller and a route associated with the reseller, a record associated with the reseller and a default reseller markup record.
- (72) Calculating the cost per unit time value further may involve locating at least one of an override record specifying a route cost per unit time amount associated with a route associated with the communication session, a reseller record associated with a reseller of the communications session, the reseller record specifying a reseller cost per unit time associated with the reseller for the communication session, a default operator markup record specifying a default cost per unit time.
- (73) The method may further involve setting as the cost per unit time the sum of the reseller rate and at least one of the route cost per unit time, the reseller cost per unit time and the default cost per unit time.
- (74) The method may further involve receiving a communication session time representing a duration of the communication session and incrementing a reseller balance by the product of the reseller rate and the communication session time.
- (75) The method may further involve receiving a communication session time representing a duration of the communication session and incrementing a system operator balance by a product of the buffer rate and the communication session time.
- (76) In accordance with another aspect of the invention, there is provided an apparatus for determining a time to permit a communication session to be conducted. The apparatus includes a processor circuit, a computer readable medium coupled to the processor circuit and encoded with instructions for directing the processor circuit to calculate a cost per unit time for the

communication session, calculate a first time value as a sum of a free time attributed to a participant in the communication session and the quotient of a funds balance held by the participant to the cost per unit time value and produce a second time value in response to the first time value and a billing pattern associated with the participant, the billing pattern including first and second billing intervals and the second time value being the time to permit a communication session to be conducted.

- (77) The instructions may include instructions for directing the processor circuit to retrieve a record associated with the participant and obtain from the record at least one of the free time and the funds balance.
- (78) The instructions may include instructions for directing the processor circuit to produce the second time value by producing a remainder value representing a portion of the second billing interval remaining after dividing the second billing interval into a difference between the first time value and the first billing interval.
- (79) The instructions may include instructions for directing the processor circuit to produce the second time value comprises setting a difference between the first time value and the remainder as the second time value.
- (80) The instructions may include instructions for directing the processor circuit to set the second time value to zero when the remainder is greater than zero and the first time value is less than the free time associated with the participant.
- (81) The instructions for directing the processor circuit to calculate the cost per unit time may include instructions for directing the processor circuit to locate a record in a database, the record comprising a markup type indicator, a markup value and a billing pattern and set a reseller rate equal to the sum of the markup value and the buffer rate.
- (82) The instructions for directing the processor circuit to locate the record in a database may include instructions for directing the processor circuit to locate at least one of a record associated with a reseller and a route associated with the reseller, a record associated with the reseller, and a default reseller markup record. The instructions for directing the processor circuit to calculate the cost per unit time value may further include instructions for directing the processor circuit to locate at least one of an override record specifying a route cost per unit time amount associated with a route associated with the communication session, a reseller record associated with a reseller of the communications session, the reseller record specifying a reseller cost per unit time associated with the reseller for the communication session, a default operator markup record specifying a default cost per unit time.
- (83) The instructions may include instructions for directing the processor circuit to set as the cost per unit time the sum of the reseller rate and at least one of the route cost per unit time, the reseller cost per unit time and the default cost per unit time.
- (84) The instructions may include instructions for directing the processor circuit to receive a communication session time representing a duration of the communication session and increment a reseller balance by the product of the reseller rate and the communication session time.
- (85) The instructions may include instructions for directing the processor circuit to receive a communication session time representing a duration of the communication session and increment a system operator balance by a product of the buffer rate and the communication session time.
- (86) In accordance with another aspect of the invention, there is provided a process for attributing charges for communications services. The process involves determining a first chargeable time in response to a communication session time and a pre-defined billing pattern, determining a user cost value in response to the first chargeable time and a free time value associated with a user of the communications services, changing an account balance associated with the user in response to a user cost per unit time. The process may further involve changing an account balance associated with a reseller of the communications services in response to a reseller cost per unit time and the communication session time and changing an account balance associated with an operator of the

communications services in response to an operator cost per unit time and the communication session time.

- (87) Determining the first chargeable time may involve locating at least one of an override record specifying a route cost per unit time and billing pattern associated with a route associated with the communication session, a reseller record associated with a reseller of the communications session, the reseller record specifying a reseller cost per unit time and billing pattern associated with the reseller for the communication session and a default record specifying a default cost per unit time and billing pattern and setting as the pre-defined billing pattern the billing pattern of the record located. The billing pattern of the record located may involve a first billing interval and a second billing interval.
- (88) Determining the first chargeable time may involve setting the first chargeable time equal to the first billing interval when the communication session time is less than or equal to the first billing interval.
- (89) Determining the first chargeable time may involve producing a remainder value representing a portion of the second billing interval remaining after dividing the second billing interval into a difference between communication session time and the first interval when the communication session time is greater than the communication session time and setting the first chargeable time to a difference between the communication session time and the remainder when the remainder is greater than zero and setting the first chargeable time to the communication session time when the remainder is not greater than zero.
- (90) The process may further involve determining a second chargeable time in response to the first chargeable time and the free time value associated with the user of the communications services when the first chargeable time is greater than or equal to the free time value associated with the user of the communications services.
- (91) Determining the second chargeable time may involve setting the second chargeable time to a difference between the first chargeable time.
- (92) The process may further involve resetting the free time value associated with the user to zero when the first chargeable time is greater than or equal to the free time value associated with the user of the communications services.
- (93) Changing an account balance associated with the user may involve calculating a user cost value in response to the second chargeable time and the user cost per unit time.
- (94) The process may further involve changing a user free cost balance in response to the user cost value.
- (95) The process may further involve setting the user cost to zero when the first chargeable time is less than the free time value associated with the user.
- (96) The process may further involve changing a user free time balance in response to the first chargeable time.
- (97) In accordance with another aspect of the invention, there is provided an apparatus for attributing charges for communications services. The apparatus includes a processor circuit, a computer readable medium in communication with the processor circuit and encoded with instructions for directing the processor circuit to determine a first chargeable time in response to a communication session time and a pre-defined billing pattern, determine a user cost value in response to the first chargeable time and a free time value associated with a user of the communications services, change an account balance associated with the user in response to a user cost per unit time.
- (98) The instructions may further include instructions for changing an account balance associated with a reseller of the communications services in response to a reseller cost per unit time and the communication session time and changing an account balance associated with an operator of the communications services in response to an operator cost per unit time and the communication session time.

- (99) The instructions for directing the processor circuit to determine the first chargeable time may further include instructions for causing the processor circuit to communicate with a database to locate at least one of an override record specifying a route cost per unit time and billing pattern associated with a route associated with the communication session, a reseller record associated with a reseller of the communications session, the reseller record specifying a reseller cost per unit time and billing pattern associated with the reseller for the communication session and a default record specifying a default cost per unit time and billing pattern and instructions for setting as the predefined billing pattern the billing pattern of the record located. The billing pattern of the record located may include a first billing interval and a second billing interval.
- (100) The instructions for causing the processor circuit to determine the first chargeable time may include instructions for directing the processor circuit to set the first chargeable time equal to the first billing interval when the communication session time is less than or equal to the first billing interval.
- (101) The instructions for causing the processor circuit to determine the first chargeable time may include instructions for producing a remainder value representing a portion of the second billing interval remaining after dividing the second billing interval into a difference between communication session time and the first interval when the communication session time is greater than the communication session time and instructions for causing the processor circuit to set the first chargeable time to a difference between the communication session time and the remainder when the remainder is greater than zero and instructions for causing the processor circuit to set the first chargeable time to the communication session time when the remainder is not greater than zero.
- (102) The instructions may further include instructions for causing the processor circuit to determine a second chargeable time in response to the first chargeable time and the free time value associated with the user of the communications services when the first chargeable time is greater than or equal to the free time value associated with the user of the communications services. (103) The instructions for causing the processor circuit to determine the second chargeable time may include instructions for causing the processor circuit to set the second chargeable time to a
- (104) The instructions may further include instructions for causing the processor circuit to reset the free time value associated with the user to zero when the first chargeable time is greater than or equal to the free time value associated with the user of the communications services.

difference between the first chargeable time.

- (105) The instructions for causing the processor circuit to change an account balance associated with the user may include instructions for causing the processor circuit to calculate a user cost value in response to the second chargeable time and the user cost per unit time.
- (106) The instructions may further include instructions for causing the processor circuit to change a user free cost balance in response to the user cost value.
- (107) The instructions may further include instructions for causing the processor circuit to set the user cost to zero when the first chargeable time is less than the free time value associated with the user.
- (108) The instructions may further include instructions for causing the processor circuit to change a user free time balance in response to the first chargeable time.
- (109) In accordance with another aspect of the invention, there is provided a computer readable medium encoded with codes for directing a processor circuit to execute one or more of the methods described above and/or variants thereof.
- (110) Other aspects and features of the present invention will become apparent to those ordinarily skilled in the art upon review of the following description of specific embodiments of the invention in conjunction with the accompanying figures.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

- (1) In drawings which illustrate embodiments of the invention,
- (2) FIG. **1** is a block diagram of a system according to a first embodiment of the invention;
- (3) FIG. **2** is a block diagram of a caller telephone according to the first embodiment of the invention;
- (4) FIG. **3** is a schematic representation of a SIP invite message transmitted between the caller telephone and a controller shown in FIG. **1**;
- (5) FIG. **4** is a block diagram of a call controller shown in FIG. **1**;
- (6) FIG. **5** is a flowchart of a process executed by the call controller shown in FIG. **1**;
- (7) FIG. **6** is a schematic representation of a routing, billing and rating (RC) request message produced by the call controller shown in FIG. **1**;
- (8) FIG. **7** is a block diagram of a processor circuit of a routing, billing, rating element of the system shown in FIG. **1**;
- (9) FIGS. **8**A-**8**D is a flowchart of a RC request message handler executed by the RC processor circuit shown in FIG. **7**;
- (10) FIG. **9** is a tabular representation of a dialing profile stored in a database accessible by the RC shown in FIG. **1**;
- (11) FIG. **10** is a tabular representation of a dialing profile for a caller using the caller telephone shown in FIG. **1**;
- (12) FIG. **11** is a tabular representation of a callee profile for a callee located in Calgary;
- (13) FIG. **12** is a tabular representation of a callee profile for a callee located in London;
- (14) FIG. **13** is a tabular representation of a Direct-in-Dial (DID) bank table record stored in the database shown in FIG. **1**;
- (15) FIG. **14** is a tabular representation of an exemplary DID bank table record for the Calgary callee referenced in FIG. **11**;
- (16) FIG. **15** is a tabular representation of a routing message transmitted from the RC to the call controller shown in FIG. **1**;
- (17) FIG. **16** is a schematic representation of a routing message buffer holding a routing message for routing a call to the Calgary callee referenced in FIG. **11**;
- (18) FIG. **17** is a tabular representation of a prefix to supernode table record stored in the database shown in FIG. **1**;
- (19) FIG. **18** is a tabular representation of a prefix to supernode table record that would be used for the Calgary callee referenced in FIG. **11**;
- (20) FIG. **19** is a tabular representation of a master list record stored in a master list table in the database shown in FIG. **1**;
- (21) FIG. **20** is a tabular representation of a populated master list record;
- (22) FIG. **21** is a tabular representation of a suppliers list record stored in the database shown in FIG. **1**;
- (23) FIG. 22 is a tabular representation of a specific supplier list record for a first supplier;
- (24) FIG. 23 is a tabular representation of a specific supplier list record for a second supplier;
- (25) FIG. **24** is a tabular representation of a specific supplier list record for a third supplier;
- (26) FIG. **25** is a schematic representation of a routing message, held in a routing message buffer, identifying to the controller a plurality of possible suppliers that may carry the call;
- (27) FIG. **26** is a tabular representation of a call block table record;
- (28) FIG. 27 is a tabular representation of a call block table record for the Calgary callee;
- (29) FIG. **28** is a tabular representation of a call forwarding table record;
- (30) FIG. 29 is a tabular representation of a call forwarding table record specific for the Calgary

callee;

- (31) FIG. **30** is a tabular representation of a voicemail table record specifying voicemail parameters to enable the caller to leave a voicemail message for the callee;
- (32) FIG. 31 is a tabular representation of a voicemail table record specific to the Calgary callee;
- (33) FIG. **32** is a schematic representation of an exemplary routing message, held in a routing message buffer, indicating call forwarding numbers and a voicemail server identifier;
- (34) FIGS. **33**A and **33**B are respective portions of a flowchart of a process executed by the RC processor for determining a time to live value;
- (35) FIG. **34** is a tabular representation of a subscriber bundle table record;
- (36) FIG. **35** is a tabular representation of a subscriber bundle record for the Vancouver caller;
- (37) FIG. **36** is a tabular representation of a bundle override table record;
- (38) FIG. **37** is a tabular representation of bundle override record for a located master list ID;
- (39) FIG. **38** is a tabular representation of a subscriber account table record;
- (40) FIG. **39** is a tabular representation of a subscriber account record for the Vancouver caller;
- (41) FIG. **40** is a flowchart of a process for producing a second time value executed by the RC processor circuit shown in FIG. **7**;
- (42) FIG. **41** is a flowchart for calculating a call cost per unit time;
- (43) FIG. **42** is a tabular representation of a system operator special rates table record;
- (44) FIG. **43** is a tabular representation of a system operator special rates table record for a reseller named Klondike;
- (45) FIG. **44** is a tabular representation of a system operator mark-up table record;
- (46) FIG. **45** is a tabular representation of a system operator mark-up table record for the reseller Klondike;
- (47) FIG. **46** is a tabular representation of a default system operator mark-up table record;
- (48) FIG. **47** is a tabular representation of a reseller special destinations table record;
- (49) FIG. **48** is a tabular representation of a reseller special destinations table record for the reseller Klondike;
- (50) FIG. **49** is a tabular representation of a reseller global mark-up table record;
- (51) FIG. **50** is a tabular representation of a reseller global mark-up table record for the reseller Klondike;
- (52) FIG. **51** is a tabular representation of a SIP bye message transmitted from either of the telephones shown in FIG. **1** to the call controller;
- (53) FIG. **52** is a tabular representation of a SIP bye message sent to the controller from the Calgary callee;
- (54) FIG. **53** is a flowchart of a process executed by the call controller for producing a RC stop message in response to receipt of a SIP bye message;
- (55) FIG. **54** is a tabular representation of an exemplary RC call stop message;
- (56) FIG. **55** is a tabular representation of an RC call stop message for the Calgary callee;
- (57) FIGS. **56**A and **56**B are respective portions of a flowchart of a RC call stop message handling routine executed by the RC shown in FIG. **1**;
- (58) FIG. **57** is a tabular representation of a reseller accounts table record;
- (59) FIG. **58** is a tabular representation of a reseller accounts table record for the reseller Klondike;
- (60) FIG. **59** is a tabular representation of a system operator accounts table record; and
- (61) FIG. **60** is a tabular representation of a system operator accounts record for the system operator described herein.

DETAILED DESCRIPTION

(62) Referring to FIG. **1**, a system for making voice over IP telephone/videophone calls is shown generally at **10**. The system includes a first super node shown generally at **11** and a second super node shown generally at **21**. The first super node **11** is located in geographical area, such as Vancouver, B.C., Canada for example and the second super node **21** is located in London, England,

for example. Different super nodes may be located in different geographical regions throughout the world to provide telephone/videophone service to subscribers in respective regions. These super nodes may be in communication with each other by high speed/high data throughput links including optical fiber, satellite and/or cable links, forming a backbone to the system. These super nodes may alternatively or, in addition, be in communication with each other through conventional internet services.

- (63) In the embodiment shown, the Vancouver supernode **11** provides telephone/videophone service to western Canadian customers from Vancouver Island to Ontario. Another node (not shown) may be located in Eastern Canada to provide services to subscribers in that area. (64) Other nodes of the type shown may also be employed within the geographical area serviced by
- a supernode, to provide for call load sharing, for example within a region of the geographical area serviced by the supernode. However, in general, all nodes are similar and have the properties described below in connection with the Vancouver supernode **11**.
- (65) In this embodiment, the Vancouver supernode includes a call controller (C) **14**, a routing controller (RC) **16**, a database **18** and a voicemail server **19** and a media relay **9**. Each of these may be implemented as separate modules on a common computer system or by separate computers, for example. The voicemail server **19** need not be included in the node and can be provided by an outside service provider.
- (66) Subscribers such as a subscriber in Vancouver and a subscriber in Calgary communicate with the Vancouver supernode using their own internet service providers which route internet traffic from these subscribers over the internet shown generally at **13** in FIG. **1**. To these subscribers the Vancouver supernode is accessible at a pre-determined internet protocol (IP) address or a fully qualified domain name that can be accessed in the usual way through a subscriber's internet service provider. The subscriber in Vancouver uses a telephone **12** that is capable of communicating with the Vancouver supernode **11** using Session Initiation Protocol (SIP) messages and the Calgary subscriber uses a similar telephone **15**, in Calgary AB.
- (67) It should be noted that throughout the description of the embodiments of this invention, the IP/UDP addresses of all elements such as the caller and callee telephones, call controller, media relay, and any others, will be assumed to be valid IP/UDP addresses directly accessible via the Internet or a private IP network, for example, depending on the specific implementation of the system. As such, it will be assumed, for example, that the caller and callee telephones will have IP/UDP addresses directly accessible by the call controllers and the media relays on their respective supernodes, and those addresses will not be obscured by Network Address Translation (NAT) or similar mechanisms. In other words, the IP/UDP information contained in SIP messages (for example the SIP Invite message or the RC Request message which will be described below) will match the IP/UDP addresses of the IP packets carrying these SIP messages.
- (68) It will be appreciated that in many situations, the IP addresses assigned to various elements of the system may be in a private IP address space, and thus not directly accessible from other elements. Furthermore, it will also be appreciated that NAT is commonly used to share a "public" IP address between multiple devices, for example between home PCs and IP telephones sharing a single Internet connection. For example, a home PC may be assigned an IP address such as 192.168.0.101 and a Voice over IP telephone may be assigned an IP address of 192.168.0.103. These addresses are located in so called "non-routable" (IP) address space and cannot be accessed directly from the Internet. In order for these devices to communicate with other computers located on the Internet, these IP addresses have to be converted into a "public" IP address, for example 24.10.10.123 assigned by the Internet Service Provider to the subscriber, by a device performing NAT, typically a home router. In addition to translating the IP addresses, NAT typically also translates UDP port numbers, for example an audio path originating at a VoIP telephone and using a UDP port 12378 at its private IP address, may have be translated to a UDP port 23465 associated with the public IP address of the NAT device. In other words, when a packet originating from the

above VoIP telephone arrives at an Internet-based supernode, the source IP/UDP address contained in the IP packet header will be 24.10.10.1:23465, whereas the source IP/UDP address information contained in the SIP message inside this IP packet will be 192.168.0.103:12378. The mismatch in the IP/UDP addresses may cause a problem for SIP-based VoW systems because, for example, a supernode will attempt to send messages to a private address of a telephone but the messages will never get there.

- (69) Referring to FIG. **1**, in an attempt to make a call by the Vancouver telephone/videophone **12** to the Calgary telephone/videophone **15**, the Vancouver telephone/videophone sends a SIP invite message to the Vancouver supernode **11** and in response, the call controller **14** sends an RC request message to the RC **16** which makes various enquiries of the database **18** to produce a routing message which is sent back to the call controller **14**. The call controller **14** then communicates with the media relay **9** to cause a communications link including an audio path and a videophone (if a videopath call) to be established through the media relay to the same node, a different node or to a communications supplier gateway as shown generally at **20** to carry audio, and where applicable, video traffic to the call recipient or callee.
- (70) Generally, the RC **16** executes a process to facilitate communication between callers and callees. The process involves, in response to initiation of a call by a calling subscriber, receiving a callee identifier from the calling subscriber, using call classification criteria associated with the calling subscriber to classify the call as a public network call or a private network call and producing a routing message identifying an address on the private network, associated with the callee when the call is classified as a private network call and producing a routing message identifying a gateway to the public network when the call is classified as a public network call. (71) Subscriber Telephone
- (72) In greater detail, referring to FIG. 2, in this embodiment, the telephone/videophone 12 includes a processor circuit shown generally at **30** comprising a microprocessor **32**, program memory **34**, an input/output (I/O) port **36**, parameter memory **38** and temporary memory **40**. The program memory **34**, I/O port **36**, parameter memory **38** and temporary memory **40** are all in communication with the microprocessor **32**. The I/O port **36** has a dial input **42** for receiving a dialled telephone/videophone number from a keypad, for example, or from a voice recognition unit or from pre-stored telephone/videophone numbers stored in the parameter memory 38, for example. For simplicity, in FIG. 2 a box labelled dialing functions 44 represents any device capable of informing the microprocessor **32** of a callee identifier, e.g., a callee telephone/videophone number. (73) The processor **32** stores the callee identifier in a dialled number buffer **45**. In this case, assume the dialled number is 2001 1050 2222 and that it is a number associated with the Calgary subscriber. The I/O port **36** also has a handset interface **46** for receiving and producing signals from and to a handset that the user may place to his ear. This interface 46 may include a BLUETOOTH™ wireless interface, a wired interface or speaker phone, for example. The handset acts as a termination point for an audio path (not shown) which will be appreciated later. The I/O port **36** also has an internet connection **48** which is preferably a high speed internet connection and is operable to connect the telephone/videophone to an internet service provider. The internet connection **48** also acts as a part of the voice path, as will be appreciated later. It will be appreciated that where the subscriber device is a videophone, a separate video path is established in the same way an audio path is established. For simplicity, the following description refers to a telephone call, but it is to be understood that a videophone call is handled similarly, with the call controller causing the media relay to facilitate both an audio path and a video path instead of only an audio path.
- (74) The parameter memory **38** has a username field **50**, a password field **52** an IP address field **53** and a SIP proxy address field **54**, for example. The user name field **50** is operable to hold a user name, which in this case is 2001 1050 8667. The user name is assigned upon subscription or registration into the system and, in this embodiment, includes a twelve digit number having a

continent code **61**, a country code **63**, a dealer code **70** and a unique number code **74**. The continent code **61** is comprised of the first or left-most digit of the user name in this embodiment. The country code **63** is comprised of the next three digits. The dealer code **70** is comprised of the next four digits and the unique number code **74** is comprised of the last four digits. The password field **52** holds a password of up to 512 characters, in this example. The IP address field **53** stores an IP address of the telephone, which for this explanation is 192.168.0.20. The SIP proxy address field **54** holds an IP protocol compatible proxy address which may be provided to the telephone through the internet connection **48** as part of a registration procedure.

- (75) The program memory **34** stores blocks of codes for directing the processor **32** to carry out the functions of the telephone, one of which includes a firewall block **56** which provides firewall functions to the telephone, to prevent access by unauthorized persons to the microprocessor **32** and memories **34**, **38** and **40** through the internet connection **48**. The program memory **34** also stores codes **57** for establishing a call ID. The call ID codes **57** direct the processor **32** to produce a call identifier having a format comprising a hexadecimal string at an IP address, the IP address being the IP address of the telephone. Thus, an exemplary call identifier might be FF10@192.168.0.20. (76) Generally, in response to picking up the handset interface **46** and activating a dialing function **44**, the microprocessor **32** produces and sends a SIP invite message as shown in FIG. **3**, to the routing controller **16** shown in FIG. **1**. This SIP invite message is essentially to initiate a call by a calling subscriber.
- (77) Referring to FIG. **3**, the SIP invite message includes a caller ID field **60**, a callee identifier field **62**, a digest parameters field **64**, a call ID field **65** an IP address field **67** and a caller UDP port field **69**. In this embodiment, the caller ID field **60** includes the user name 2001 1050 8667 that is the Vancouver user name stored in the user name field **50** of the parameter memory **38** in the telephone **12** shown in FIG. **2**. In addition, referring back to FIG. **3**, the callee identifier field **62** includes a callee identifier which in this embodiment is the user name 2001 1050 2222 that is the dialled number of the Calgary subscriber stored in the dialled number buffer **45** shown in FIG. **2**. The digest parameters field **64** includes digest parameters and the call ID field **65** includes a code comprising a generated prefix code (FF10) and a suffix which is the Internet Protocol (IP) address of the telephone **12** stored in the IP address field **53** of the telephone. The IP address field **67** holds the IP address assigned to the telephone, in this embodiment 192.168.0.20, and the caller UDP port field **69** includes a UDP port identifier identifying a UDP port at which the audio path will be terminated at the caller's telephone.
- (78) Call Controller
- (79) Referring to FIG. **4**, a call controller circuit of the call controller **14** (FIG. **1**) is shown in greater detail at **100**. The call controller circuit **100** includes a microprocessor **102**, program memory **104** and an I/O port **106**. The circuit **100** may include a plurality of microprocessors, a plurality of program memories and a plurality of I/O ports to be able to handle a large volume of calls. However, for simplicity, the call controller circuit **100** will be described as having only one microprocessor **102**, program memory **104** and I/O port **106**, it being understood that there may be more.
- (80) Generally, the I/O port **106** includes an input **108** for receiving messages such as the SIP invite message shown in FIG. **3**, from the telephone shown in FIG. **2**. The I/O port **106** also has an RC request message output **110** for transmitting an RC request message to the RC **16** of FIG. **1**, an RC message input **112** for receiving routing messages from the RC **16**, a gateway output **114** for transmitting messages to one of the gateways **20** shown in FIG. **1** to advise the gateway to establish an audio path, for example, and a gateway input **116** for receiving messages from the gateway. The I/O port **106** further includes a SIP output **118** for transmitting messages to the telephone **12** to advise the telephone of the IP addresses of the gateways which will establish the audio path. The I/O port **106** further includes a voicemail server input and output **117**, **119** respectively for communicating with the voicemail server **19** shown in FIG. **1**.

- (81) While certain inputs and outputs have been shown as separate, it will be appreciated that some may be a single IP address and IP port. For example, the messages sent to the RC **16** and received from the RC **16** may be transmitted and received on the same single IP port.
- (82) The program memory **104** includes blocks of code for directing the microprocessor **102** to carry out various functions of the call controller **14**. For example, these blocks of code include a first block **120** for causing the call controller circuit **100** to execute a SIP invite to RC request process to produce an RC request message in response to a received SIP invite message. In addition, there is a routing message to gateway message block **122** which causes the call controller circuit **100** to produce a gateway query message in response to a received routing message from the RC **16**.
- (83) Referring to FIG. 5, the SIP invite to RC request process is shown in more detail at **120**. On receipt of a SIP invite message of the type shown in FIG. 3, block 122 of FIG. 5 directs the call controller circuit **100** of FIG. **4** to authenticate the user. This may be done, for example, by prompting the user for a password, by sending a message back to the telephone 12 which is interpreted at the telephone as a request for a password entry or the password may automatically be sent to the call controller **14** from the telephone, in response to the message. The call controller **14** may then make enquiries of databases to which it has access, to determine whether or not the user's password matches a password stored in the database. Various functions may be used to pass encryption keys or hash codes back and forth to ensure that the transmittal of passwords is secure. (84) Should the authentication process fail, the call controller circuit **100** is directed to an error handling routine **124** which causes messages to be displayed at the telephone **12** to indicate there was an authentication problem. If the authentication procedure is passed, block **121** directs the call controller circuit **100** to determine whether or not the contents of the caller ID field **60** of the SIP invite message received from the telephone is an IP address. If it is an IP address, then block **123** directs the call controller circuit **100** to set the contents of a type field variable maintained by the microprocessor **102** to a code representing that the call type is a third party invite. If at block **121** the caller ID field contents do not identify an IP address, then block **125** directs the microprocessor to set the contents of the type field to a code indicating that the call is being made by a system subscriber. Then, block **126** directs the call controller circuit to read the call identifier **65** provided in the SIP invite message from the telephone 12, and at block 128 the processor is directed to produce an RC request message that includes that call ID. Block 129 then directs the call controller circuit **100** to send the RC request to the RC **16**.
- (85) Referring to FIG. **6**, an RC request message is shown generally at **150** and includes a caller field **152**, a callee field **154**, a digest field **156**, a call ID field **158** and a type field **160**. The caller, callee, digest call ID fields **152**, **154**, **156** and **158** contain copies of the caller, callee, digest parameters and call ID fields **60**, **62**, **64** and **65** of the SIP invite message shown in FIG. **3**. The type field **160** contains the type code established at blocks **123** or **125** of FIG. **5** to indicate whether the call is from a third party or system subscriber, respectively. The caller identifier field may include a PSTN number or a system subscriber username as shown, for example.
- (86) Routing Controller (RC)
- (87) Referring to FIG. **7**, the RC **16** is shown in greater detail and includes an RC processor circuit shown generally at **200**. The RC processor circuit **200** includes a processor **202**, program memory **204**, a table memory **206**, buffer memory **207**, and an I/O port **208**, all in communication with the processor **202**. (As earlier indicated, there may be a plurality of processor circuits **(202)**, memories **(204)**, etc.) The buffer memory **207** includes a caller id buffer **209** and a callee id buffer **211**. (88) The I/O port **208** includes a database request port **210** through which a request to the database **(18** shown in FIG. **1)** can be made and includes a database response port **212** for receiving a reply from the database **18**. The I/O port **208** further includes an RC request message input **214** for receiving the RC request message from the call controller **(14** shown in FIG. **1)** and includes a routing message output **216** for sending a routing message back to the call controller **14**. The I/O

- port **208** thus acts to receive caller identifier and a callee identifier contained in the RC request message from the call controller, the RC request message being received in response to initiation of a call by a calling subscriber.
- (89) The program memory **204** includes blocks of codes for directing the processor **202** to carry out various functions of the RC (**16**). One of these blocks includes an RC request message handler **250** which directs the RC to produce a routing message in response to a received RC request message. The RC request message handler process is shown in greater detail at **250** in FIGS. **8**A through **8**D. (90) RC Request Message Handler
- (91) Referring to FIG. 8A, the RC request message handler begins with a first block 252 that directs the RC processor circuit (200) to store the contents of the RC request message (150) in buffers in the buffer memory **207** of FIG. **7**, one of which includes the caller ID buffer **209** of FIG. 7 for separately storing the contents of the callee field **154** of the RC request message. Block **254** then directs the RC processor circuit to use the contents of the caller field **152** in the RC request message shown in FIG. **6**, to locate and retrieve from the database **18** a record associating calling attributes with the calling subscriber. The located record may be referred to as a dialing profile for the caller. The retrieved dialing profile may then be stored in the buffer memory **207**, for example. (92) Referring to FIG. 9, an exemplary data structure for a dialing profile is shown generally at 253 and includes a user name field **258**, a domain field **260**, and calling attributes comprising a national dialing digits (NDD) field **262**, an international dialing digits (IDD) field **264**, a country code field **266**, a local area codes field **267**, a caller minimum local length field **268**, a caller maximum local length field **270**, a reseller field **273**, a maximum number of concurrent calls field **275** and a current number of concurrent calls field **277**. Effectively the dialing profile is a record identifying calling attributes of the caller identified by the caller identifier. More generally, dialing profiles represent calling attributes of respective subscribers.
- (93) An exemplary caller profile for the Vancouver subscriber is shown generally at **276** in FIG. **10** and indicates that the user name field **258** includes the user name (2001 1050 8667) that has been assigned to the subscriber and is stored in the user name field **50** in the telephone as shown in FIG. **2**.
- (94) Referring back to FIG. **10**, the domain field **260** includes a domain name as shown at **282**, including a node type identifier **284**, a location code identifier **286**, a system provider identifier **288** and a domain portion **290**. The domain field **260** effectively identifies a domain or node associated with the user identified by the contents of the user name field **258**. In this embodiment, the node type identifier **284** includes the code "sp" identifying a supernode and the location identifier **286** identifies the supernode as being in Vancouver (YVR). The system provider identifier **288** identifies the company supplying the service and the domain portion **290** identifies the "com" domain.
- (95) The national dialled digit field **262** in this embodiment includes the digit "1" and, in general, includes a number specified by the International Telecommunications Union (ITU) Telecommunications Standardization Sector (ITU-T) E.164 Recommendation which assigns national dialing digits to countries.
- (96) The international dialing digit field **264** includes a code also assigned according to the ITU-T according to the country or location of the user.
- (97) The country code field **266** also includes the digit "1" and, in general, includes a number assigned according to the ITU-T to represent the country in which the user is located.
- (98) The local area codes field **267** includes a list of area codes that have been assigned by the ITU-T to the geographical area in which the subscriber is located. The caller minimum and maximum local number length fields **268** and **270** hold numbers representing minimum and maximum local number lengths permitted in the area code(s) specified by the contents of the local area codes field **267**. The reseller field **273** is optional and holds a code identifying a retailer of the services, in this embodiment "Klondike". The maximum number of concurrent calls field **275** holds a code

- identifying the maximum number of concurrent calls that the user is entitled to cause to concurrently exist. This permits more than one call to occur concurrently while all calls for the user are billed to the same account. The current number of concurrent calls field **277** is initially 0 and is incremented each time a concurrent call associated with the user is initiated and is decremented when a concurrent call is terminated.
- (99) The area codes associated with the user are the area codes associated with the location code identifier **286** of the contents of the domain field **260**.
- (100) A dialing profile of the type shown in FIG. **9** is produced whenever a user registers with the system or agrees to become a subscriber to the system. Thus, for example, a user wishing to subscribe to the system may contact an office maintained by a system operator and personnel in the office may ask the user certain questions about his location and service preferences, whereupon tables can be used to provide office personnel with appropriate information to be entered into the user name **258**, domain **260**, NDD **262**, IDD **264**, country code **266**, local area codes **267**, caller minimum and maximum local length fields **268** and **270** reseller field **273** and concurrent call fields **275** and **277** to establish a dialing profile for the user.
- (101) Referring to FIGS. **11** and **12**, callee dialing profiles for users in Calgary and London, respectively for example, are shown.
- (102) In addition to creating dialing profiles when a user registers with the system, a direct-in-dial (DID) record of the type shown at **278** in FIG. **13** is added to a direct-in-dial bank table in the database (**18** in FIG. **1**) to associate the username and a host name of the supernode with which the user is associated, with an E.164 number associated with the user on the PSTN network.
- (103) An exemplary DID table record entry for the Calgary callee is shown generally at **300** in FIG. **14**. The user name field **281** and user domain field **272** are analogous to the user name and user domain fields **258** and **260** of the caller dialing profile shown in FIG. **10**. The contents of the DID field **274** include a E.164 public telephone number including a country code **283**, an area code **285**, an exchange code **287** and a number **289**. If the user has multiple telephone numbers, then multiple records of the type shown at **300** would be included in the DID bank table, each having the same user name and user domain, but different DID field **274** contents reflecting the different telephone numbers associated with that user.
- (104) In addition to creating dialing profiles as shown in FIG. **9** and DID records as shown in FIG. **13** when a user registers with the system, call blocking records of the type shown in FIG. **26**, call forwarding records of the type shown in FIG. **28** and voicemail records of the type shown in FIG. **30** may be added to the database **18** when a new subscriber is added to the system.
- (105) Referring back to FIG. **8**A, after retrieving a dialing profile for the caller, such as shown at **276** in FIG. **10**, the RC processor circuit **200** is directed to block **256** which directs the processor circuit (**200**) to determine whether the contents of the concurrent call field **277** are less then the contents of the maximum concurrent call field **275** of the dialing profile for the caller and, if so, block **271** directs the processor circuit to increment the contents of the concurrent call field **277**. If the contents of concurrent call field **277** are equal to or greater than the contents of the maximum concurrent call field **275**, block **259** directs the processor circuit **200** to send an error message back to the call controller (**14**) to cause the call controller to notify the caller that the maximum number of concurrent calls has been reached and no further calls can exist concurrently, including the presently requested call.
- (106) Assuming block **256** allows the call to proceed, the RC processor circuit **200** is directed to perform certain checks on the callee identifier provided by the contents of the callee field **154** in FIG. **6**, of the RC request message **150**. These checks are shown in greater detail in FIG. **8**B. (107) Referring to FIG. **8**B, the processor (**202** in FIG. **7**) is directed to a first block **257** that causes it to determine whether a digit pattern of the callee identifier (**154**) provided in the RC request message (**150**) includes a pattern that matches the contents of the international dialing digits (IDD) field **264** in the caller profile shown in FIG. **10**. If so, then block **259** directs the processor (**202**) to

set a call type code identifier variable maintained by the processor to indicate that the call is an international call and block **261** directs the processor to produce a reformatted callee identifier by reformatting the callee identifier into a predefined digit format. In this embodiment, this is done by removing the pattern of digits matching the IDD field contents **264** of the caller dialing profile to effectively shorten the callee identifier. Then, block **263** directs the processor **202** to determine whether or not the callee identifier has a length which meets criteria establishing it as a number compliant with the E.164 Standard set by the ITU. If the length does not meet this criteria, block **265** directs the processor **202** to send back to the call controller **(14)** a message indicating the length is not correct. The process is then ended. At the call controller **14**, routines (not shown) stored in the program memory **104** may direct the processor **(102** of FIG. **4)** to respond to the incorrect length message by transmitting a message back to the telephone **(12** shown in FIG. **1)** to indicate that an invalid number has been dialled.

(108) Still referring to FIG. **8**B, if the length of the amended callee identifier meets the criteria set forth at block **263**, block **269** directs the processor (**202** of FIG. **7**) to make a database request to determine whether or not the amended callee identifier is found in a record in the direct-in-dial bank (DID) table. Referring back to FIG. **8**B, at block **269**, if the processor **202** receives a response from the database indicating that the reformatted callee identifier produced at block **261** is found in a record in the DID bank table, then the callee is a subscriber to the system and the call is classified as a private network call by directing the processor to block **279** which directs the processor to copy the contents of the corresponding user name field (**281** in FIG. **14**) from the callee DID bank table record (**300** in FIG. **14**) into the callee ID buffer (**211** in FIG. **7**). Thus, the processor **202** locates a subscriber user name associated with the reformatted callee identifier. The processor **202** is then directed to point B in FIG. **8**A.

(109) Subscriber to Subscriber Calls Between Different Nodes

- (110) Referring to FIG. **8**A, block **280** directs the processor (**202** of FIG. **7**) to execute a process to determine whether or not the node associated with the reformatted callee identifier is the same node that is associated with the caller identifier. To do this, the processor **202** determines whether or not a prefix (e.g., continent code **61**) of the callee name held in the callee ID buffer (**211** in FIG. **7**), is the same as the corresponding prefix of the caller name held in the username field **258** of the caller dialing profile shown in FIG. **10**. If the corresponding prefixes are not the same, block **302** in FIG. **8**A directs the processor (**202** in FIG. **7**) to set a call type flag in the buffer memory (**207** in FIG. **7**) to indicate the call is a cross-domain call. Then, block **350** of FIG. **8**A directs the processor (**202** of FIG. **7**) to produce a routing message identifying an address on the private network with which the callee identified by the contents of the callee ID buffer is associated and to set a time to live for the call at a maximum value of 99999, for example.
- (111) Thus the routing message includes a caller identifier, a call identifier set according to a username associated with the located DID bank table record and includes an identifier of a node on the private network with which the callee is associated.
- (112) The node in the system with which the callee is associated is determined by using the callee identifier to address a supernode table having records of the type as shown at **370** in FIG. **17**. Each record **370** has a prefix field **372** and a supernode address field **374**. The prefix field **372** includes the first n digits of the callee identifier. In this embodiment n=2. The supernode address field **374** holds a code representing the IP address or a fully qualified domain name of the node associated with the code stored in the callee identifier prefix field **372**. Referring to FIG. **18**, for example, if the prefix is 20, the supernode address associated with that prefix is sp.yvr.digifonica.com. (113) Referring to FIG. **15**, a generic routing message is shown generally at **352** and includes an optional supplier prefix field **354**, and optional delimiter field **356**, a callee user name field **358**, at least one route field **360**, a time to live field **362** and other fields **364**. The optional supplier prefix field **354** holds a code for identifying supplier traffic. The optional delimiter field **356** holds a symbol that delimits the supplier prefix code from the callee user name field **358**. In this

- embodiment, the symbol is a number sign (#). The route field **360** holds a domain name or IP address of a gateway or node that is to carry the call, and the time to live field **362** holds a value representing the number of seconds the call is permitted to be active, based on subscriber available minutes and other billing parameters.
- (114) Referring to FIG. **8**A and FIG. **16**, an example of a routing message produced by the processor at block **350** for a caller associated with a different node than the caller is shown generally at **366** and includes only a callee field **359**, a route field **361** and a time to live field **362**. (115) Referring to FIG. **8**A, having produced a routing message as shown in FIG. **16**, block **381** directs the processor (**202** of FIG. **7**) to send the routing message shown in FIG. **16** to the call controller **14** shown in FIG. **1**.
- (116) Referring back to FIG. **8**B, if at block **257**, the callee identifier stored in the callee id buffer (**211** in FIG. **7**) does not begin with an international dialing digit, block **380** directs the processor (**202**) to determine whether or not the callee identifier begins with the same national dial digit code as assigned to the caller. To do this, the processor (**202**) is directed to refer to the retrieved caller dialing profile as shown in FIG. **10**. In FIG. **10**, the national dialing digit code **262** is the number **1**. Thus, if the callee identifier begins with the number **1**, then the processor (**202**) is directed to block **382** in FIG. **8**B.
- (117) Block **382** directs the processor (**202** of FIG. **7**) to examine the callee identifier to determine whether or not the digits following the NDD digit identify an area code that is the same as any of the area codes identified in the local area codes field **267** of the caller dialing profile **276** shown in FIG. **10**. If not, block **384** of FIG. **8**B directs the processor **202** to set the call type flag to indicate that the call is a national call. If the digits following the NDD digit identify an area code that is the same as a local area code associated with the caller as indicated by the caller dialing profile, block **386** directs the processor **202** to set the call type flag to indicate a local call, national style. After executing blocks **384** or **386**, block **388** directs the processor **202** to format the callee identifier into a pre-defined digit format to produce a re-formatted callee identifier by removing the national dialled digit and prepending a caller country code identified by the country code field **266** of the caller dialing profile shown in FIG. **10**. The processor (**202**) is then directed to block **263** of FIG. **8**B to perform other processing as already described above.
- (118) If at block **380**, the callee identifier does not begin with a national dialled digit, block **390** directs the processor (**202**) to determine whether the callee identifier begins with digits that identify the same area code as the caller. Again, the reference for this is the retrieved caller dialing profile shown in FIG. **10**. The processor (**202**) determines whether or not the first few digits of the callee identifier identify an area code corresponding to the local area code field **267** of the retrieved caller dialing profile. If so, then block **392** directs the processor **202** to set the call type flag to indicate that the call is a local call and block **394** directs the processor (**202**) to format the callee identifier into a pre-defined digit format to produce a reformatted callee identifier by prepending the caller country code to the callee identifier, the caller country code being determined from the country code field **266** of the retrieved caller dialing profile shown in FIG. **10**. The processor (**202**) is then directed to block **263** for further processing as described above.
- (119) Referring back to FIG. **8**B, at block **390**, the callee identifier does not start with the same area code as the caller, block **396** directs the processor (**202** of FIG. **7**) to determine whether the number of digits in the callee identifier, i.e. the length of the callee identifier, is within the range of digits indicated by the caller minimum local number length field **268** and the caller maximum local number length field **270** of the retrieved caller dialing profile shown in FIG. **10**. If so, then block **398** directs the processor (**202**) to set the call type flag to indicate a local call and block **400** directs the processor (**202**) to format the callee identifier into a pre-defined digit format to produce a reformatted callee identifier by prepending to the callee identifier the caller country code (as indicated by the country code field **266** of the retrieved caller dialing profile shown in FIG. **10**) followed by the caller area code (as indicated by the local area code field **267** of the caller profile

shown in FIG. **10**). The processor (**202**) is then directed to block **263** of FIG. **8**B for further processing as described above.

(120) Referring back to FIG. **8**B, if at block **396**, the callee identifier has a length that does not fall within the range specified by the caller minimum local number length field (**268** in FIG. **10**) and the caller maximum local number length field (**270** in FIG. **10**), block **402** directs the processor **202** of FIG. **7** to determine whether or not the callee identifier identifies a valid user name. To do this, the processor **202** searches through the database (**18** of FIG. **10** of dialing profiles to find a dialing profile having user name field contents (**258** in FIG. **10**) that match the callee identifier. If no match is found, block **404** directs the processor (**202**) to send an error message back to the call controller (**14**). If at block **402**, a dialing profile having a user name field **258** that matches the callee identifier is found, block **406** directs the processor **202** to set the call type flag to indicate that the call is a private network call and then the processor is directed to block **280** of FIG. **8**A. Thus, the call is classified as a private network call when the callee identifier identifies a subscriber to the private network.

(121) From FIG. **8**B, it will be appreciated that there are certain groups of blocks of codes that direct the processor **202** in FIG. **7** to determine whether the callee identifier has certain features such as an international dialing digit, a national dialing digit, an area code and a length that meet certain criteria, and cause the processor **202** to reformat the callee identifier stored in the callee id buffer **211**, as necessary into a predetermined target format including only a country code, area code, and a normal telephone number, for example, to cause the callee identifier to be compatible with the E.164 number plan standard in this embodiment. This enables block **269** in FIG. **8**B to have a consistent format of callee identifiers for use in searching through the DID bank table records of the type shown in FIG. 13 to determine how to route calls for subscriber to subscriber calls on the same system. Effectively, therefore blocks **257**, **380**, **390**, **396** and **402** establish call classification criteria for classifying the call as a public network call or a private network call. Block **269** classifies the call, depending on whether or not the formatted callee identifier has a DID bank table record and this depends on how the call classification criteria are met and block 402 directs the processor **202** of FIG. **7** to classify the call as a private network call when the callee identifier complies with a pre-defined format, i.e. is a valid user name and identifies a subscriber to the private network, after the callee identifier has been subjected to the classification criteria of blocks **257**, **380**, **390** and **396**.

(122) Subscriber to Non-Subscriber Calls

(123) Not all calls will be subscriber to subscriber calls and this will be detected by the processor **202** of FIG. **7** when it executes block **269** in FIG. **8**B, and does not find a DID bank table record that is associated with the callee, in the DID bank table. When this occurs, the call is classified as a public network call by directing the processor **202** to block **408** of FIG. **8**B which causes it to set the contents of the callee id buffer **211** of FIG. **7** equal to the newly formatted callee identifier, i.e., a number compatible with the E.164 standard. Then, block **410** of FIG. **8**B directs the processor (**202**) to search a database of route or master list records associating route identifiers with dialing codes shown in FIG. **19** to locate a router having a dialing code having a number pattern matching at least a portion of the reformatted callee identifier.

(124) Referring to FIG. **19**, a data structure for a master list or route list record is shown. Each master list record includes a master list ID field **500**, a dialing code field **502**, a country code field **504**, a national sign number field **506**, a minimum length field **508**, a maximum length field **510**, a national dialed digit field **512**, an international dialed digit field **514** and a buffer rate field **516**. (125) The master list ID field **500** holds a unique code such as 1019, for example, identifying the record. The dialing code field **502** holds a predetermined number pattern that the processor **202** of FIG. **7** uses at block **410** in FIG. **8**B to find the master list record having a dialing code matching the first few digits of the amended callee identifier stored in the callee id buffer **211**. The country code field **504** holds a number representing the country code associated with the record and the

national sign number field **506** holds a number representing the area code associated with the record. (It will be observed that the dialing code is a combination of the contents of the country code field **504** and the national sign number field **506**.) The minimum length field **508** holds a number representing the minimum length of digits associated with the record and the maximum length field **51** holds a number representing the maximum number of digits in a number with which the record may be compared. The national dialed digit (NDD) field **512** holds a number representing an access code used to make a call within the country specified by the country code, and the international dialed digit (IDD) field **514** holds a number representing the international prefix needed to dial a call from the country indicated by the country code.

- (126) Thus, for example, a master list record may have a format as shown in FIG. **20** with exemplary field contents as shown.
- (127) Referring back to FIG. **8**B, using the country code and area code portions of the reformatted callee identifier stored in the callee id buffer **211**, block **410** directs the processor **202** of FIG. **7** to find a master list record such as the one shown in FIG. **20** having a dialing code that matches the country code (1) and area code (604) of the callee identifier. Thus, in this example, the processor (**202**) would find a master list record having an ID field containing the number 1019. This number may be referred to as a route ID. Thus, a route ID number is found in the master list record associated with a predetermined number pattern in the reformatted callee identifier.
- (128) After executing block **410** in FIG. **8**B, the process continues as shown in FIG. **8**D. Referring to FIG. **8**D, block **412** directs the processor **202** of FIG. **7** to use the route ID number to search a database of supplier records associating supplier identifiers with route identifiers to locate at least one supplier record associated with the route identifier to identify at least one supplier operable to supply a communications link for the route.
- (129) Referring to FIG. 21, a data structure for a supplier list record is shown. Supplier list records include a supplier ID field 540, a master list ID field 542, an optional prefix field 544, a specific route identifier field 546, a NDD/IDD rewrite field 548, a rate field 550, and a timeout field 551. The supplier ID field 540 holds a code identifying the name of the supplier and the master list ID field 542 holds a code for associating the supplier record with a master list record. The prefix field 544 holds a string used to identify the supplier traffic and the specific route identifier field 546 holds an IP address of a gateway operated by the supplier indicated by the supplier ID field 540. The NDD/IDD rewrite field 548 holds a code representing a rewritten value of the NDD/IDD associated with this route for this supplier, and the rate field 550 holds a code indicating the cost per second to the system operator to use the route provided by the gateway specified by the contents of the route identifier field 546. The timeout field 551 holds a code indicating a time that the call controller should wait for a response from the associated gateway before giving up and trying the next gateway. This time value may be in seconds, for example. Exemplary supplier records are shown in FIGS. 22, 23 and 24 for the exemplary suppliers shown at 20 in FIG. 1, namely Telus, Shaw and Sprint.
- (130) Referring back to FIG. **8**D, at block **412** the processor **202** finds all supplier records that identify the master list ID found at block **410** of FIG. **8**B.
- (131) Referring back to FIG. **8**D, block **560** directs the processor **202** of FIG. **7** to begin to produce a routing message of the type shown in FIG. **15**. To do this, the processor **202** loads a routing message buffer as shown in FIG. **25** with a supplier prefix of the least costly supplier where the least costly supplier is determined from the rate fields **550** of FIG. **21** of the records associated with respective suppliers.
- (132) Referring to FIGS. **22-24**, in the embodiment shown, the supplier "Telus" has the lowest number in the rate field **550** and therefore the prefix **4973** associated with that supplier is loaded into the routing message buffer shown in FIG. **25** first. Block **562** in FIG. **8**D directs the processor to delimit the prefix **4973** by the number sign (#) and to next load the reformatted callee identifier into the routing message buffer shown in FIG. **25**. At block **563** of FIG. **8**D, the contents of the

- route identifier field **546** of FIG. **21** of the record associated with the supplier "Telus" are added by the processor **202** of FIG. **7** to the routing message buffer shown in FIG. **25** after an @ sign delimiter, and then block **564** in FIG. **8**D directs the processor to get a time to live value, which in one embodiment may be 3600 seconds, for example. Block **566** then directs the processor **202** to load this time to live value and the timeout value (**551**) in FIG. **21** in the routing message buffer of FIG. **25**. Accordingly, a first part of the routing message for the Telus gateway is shown generally at **570** in FIG. **25**.
- (133) Referring back to FIG. **8**D, block **571** directs the processor **202** back to block **560** and causes it to repeat blocks **560**, **562**, **563**, **564** and **566** for each successive supplier until the routing message buffer is loaded with information pertaining to each supplier identified by the processor at block **412**. Thus, a second portion of the routing message as shown at **572** in FIG. **25** relates to the second supplier identified by the record shown in FIG. **23**. Referring back to FIG. **25**, a third portion of the routing message as shown at **574** and is associated with a third supplier as indicated by the supplier record shown in FIG. **24**.
- (134) Consequently, referring to FIG. **25**, the routing message buffer holds a routing message identifying a plurality of different suppliers able to provide gateways to the public telephone network (i.e. specific routes) to establish at least part of a communication link through which the caller may contact the callee. In this embodiment, each of the suppliers is identified, in succession, according to rate. Other criteria for determining the order in which suppliers are listed in the routing message may include preferred supplier priorities which may be established based on service agreements, for example.
- (135) Referring back to FIG. **8**D, block **568** directs the processor **202** of FIG. **7** to send the routing message shown in FIG. **25** to the call controller **14** in FIG. **1**.
- (136) Subscriber to Subscriber Calls within the Same Node
- (137) Referring back to FIG. **8**A, if at block **280**, the callee identifier received in the RC request message has a prefix that identifies the same node as that associated with the caller, block **600** directs the processor **202** to use the callee identifier in the callee id buffer **211** to locate and retrieve a dialing profile for the callee. The dialing profile may be of the type shown in FIG. **11** or **12**, for example. Block **602** of FIG. **8**A then directs the processor **202** of FIG. **7** to get call block, call forward and voicemail records from the database **18** of FIG. **1** based on the user name identified in the callee dialing profile retrieved by the processor at block **600**. Call block, call forward and voicemail records may be as shown in FIGS. **26**, **27**, **28** and **30** for example.
- (138) Referring to FIG. **26**, the call block records include a user name field **604** and a block pattern field **606**. The user name field holds a user name corresponding to the user name in the user name field **(258** in FIG. **10)** of the callee profile and the block pattern field **606** holds one or more E.164-compatible numbers or user names identifying PSTN numbers or system subscribers from whom the subscriber identified in the user name field **604** does not wish to receive calls.
- (139) Referring to FIG. **8**A and FIG. **27**, block **608** directs the processor **202** of FIG. **7** to determine whether or not the caller identifier received in the RC request message matches a block pattern stored in the block pattern field **606** of the call block record associated with the callee identified by the contents of the user name field **604** in FIG. **26**. If the caller identifier matches a block pattern, block **610** directs the processor to send a drop call or non-completion message to the call controller (**14**) and the process is ended. If the caller identifier does not match a block pattern associated with the callee, block **609** directs the processor to store the username and domain of the callee, as determined from the callee dialing profile, and a time to live value in the routing message buffer as shown at **650** in FIG. **32**. Referring back to FIG. **8**A, block **612** then directs the processor **202** to determine whether or not call forwarding is required.
- (140) Referring to FIG. **28**, the call forwarding records include a user name field **614**, a destination number field **616**, and a sequence number field **618**. The user name field **614** stores a code representing a user with which the record is associated. The destination number field **616** holds a

user name representing a number to which the current call should be forwarded, and the sequence number field **618** holds an integer number indicating the order in which the user name associated with the corresponding destination number field **616** should be attempted for call forwarding. The call forwarding table may have a plurality of records for a given user. The processor **202** of FIG. **7** uses the contents of the sequence number field **618** to place the records for a given user in order. As will be appreciated below, this enables the call forwarding numbers to be tried in an ordered sequence.

- (141) Referring to FIG. **8**A and FIG. **29**, if at block **612**, the call forwarding record for the callee identified by the callee identifier contains no contents in the destination number field **616** and accordingly no contents in the sequence number field **618**, there are no call forwarding entries for this callee, and the processor **202** is directed to block **620** in FIG. **8**C. If there are entries in the call forwarding table **27**, block **622** in FIG. **8**A directs the processor **202** to search the dialing profile table to find a dialing profile record as shown in FIG. **9**, for the user identified by the destination number field **616** of the call forward record shown in FIG. **28**. The processor **202** of FIG. **7** is further directed to store the username and domain for that user and a time to live value in the routing message buffer as shown at **652** in FIG. **32**, to produce a routing message as illustrated. This process is repeated for each call forwarding record associated with the callee identified by the callee id buffer **211** in FIG. **7** to add to the routing message buffer all call forwarding usernames and domains associated with the callee.
- (142) Referring back to FIG. **8**A, if at block **612** there are no call forwarding records, then at block **620** in FIG. **8**C the processor **202** is directed to determine whether or not the user identified by the callee identifier has paid for voicemail service. This is done by checking to see whether or not a flag is set in a voicemail record of the type shown in FIG. **30** in a voicemail table stored in the database **18** shown in FIG. **1**.
- (143) Referring to FIG. 30, voicemail records in this embodiment may include a user name field 624, a voicemail server field 626, a seconds to voicemail field 628 and an enable field 630. The user name field 624 stores the user name of the callee. The voicemail server field 626 holds a code identifying a domain name of a voicemail server associated with the user identified by the user name field 624. The seconds to voicemail field 628 holds a code identifying the time to wait before engaging voicemail, and the enable field 630 holds a code representing whether or not voicemail is enabled for the user. Referring back to FIG. 8C, at block 620 if the processor 202 of FIG. 7 finds a voicemail record as shown in FIG. 30 having user name field 624 contents matching the callee identifier, the processor is directed to examine the contents of the enabled field 630 to determine whether or not voicemail is enabled. If voicemail is enabled, then block 640 in FIG. 8C directs the processor 202 to FIG. 7 to store the contents of the voicemail server field 626 and the contents of the seconds to voicemail field 628 in the routing message buffer, as shown at 654 in FIG. 32. Block 642 then directs the processor 202 to get time to live values for each path specified by the routing message according to the cost of routing and the user's balance. These time to live values are then appended to corresponding paths already stored in the routing message buffer.
- (144) Referring back to FIG. **8**C, block **644** then directs the processor **202** of FIG. **7** to store the IP address of the current node in the routing message buffer as shown at **656** in FIG. **32**. Block **646** then directs the processor **202** to send the routing message shown in FIG. **32** to the call controller **14** in FIG. **1**. Thus in the embodiment described the routing controller will produce a routing message that will cause at least one of the following: forward the call to another party, block the call and direct the caller to a voicemail server.
- (145) Referring back to FIG. **1**, the routing message whether of the type shown in FIG. **16**, **25** or **32**, is received at the call controller **14** and the call controller interprets the receipt of the routing message as a request to establish a call.
- (146) Referring to FIG. **4**, the program memory **104** of the call controller **14** includes a routing to gateway routine depicted generally at **122**.

- (147) Where a routing message of the type shown in FIG. **32** is received by the call controller **14**, the routing to gateway routine **122** shown in FIG. **4** may direct the processor **102** cause a message to be sent back through the internet **13** shown in FIG. **1** to the callee telephone **15**, knowing the IP address of the callee telephone **15** from the user name.
- (148) Alternatively, if the routing message is of the type shown in FIG. **16**, which identifies a domain associated with another node in the system, the call controller may send a SIP invite message along the high speed backbone **17** connected to the other node. The other node functions as explained above, in response to receipt of a SIP invite message.
- (149) If the routing message is of the type shown in FIG. **25** where there are a plurality of gateway suppliers available, the call controller sends a SIP invite message to the first supplier, in this case Telus, using a dedicated line or an internet connection to determine whether or not Telus is able to handle the call. If the Telus gateway returns a message indicating it is not able to handle the call, the call controller **14** then proceeds to send a SIP invite message to the next supplier, in this case Shaw. The process is repeated until one of the suppliers responds indicating that it is available to carry the call. Once a supplier responds indicating that it is able to carry the call, the supplier sends back to the call controller **14** an IP address for a gateway provided by the supplier through which the call or audio path of the call will be carried. This IP address is sent in a message from the call controller **14** to the media relay **9** which responds with a message indicating an IP address to which the caller telephone should send its audio/video, traffic and an IP address to which the gateway should send its audio/video for the call. The call controller conveys the IP address at which the media relay expects to receive audio/video from the caller telephone, to the caller telephone 12 in a message. The caller telephone replies to the call controller with an IP address at which it would like to receive audio/video and the call controller conveys that IP address to the media relay. The call may then be conducted between the caller and callee through the media relay and gateway. (150) Referring back to FIG. 1, if the call controller 14 receives a routing message of the type shown in FIG. 32, and which has at least one call forwarding number and/or a voicemail number, the call controller attempts to establish a call to the callee telephone **15** by seeking from the callee telephone a message indicating an IP address to which the media relay should send audio/video. If no such message is received from the callee telephone, no call is established. If no call is established within a pre-determined time, the call controller **14** attempts to establish a call with the next user identified in the call routing message in the same manner. This process is repeated until all call forwarding possibilities have been exhausted, in which case the call controller communicates with the voicemail server **19** identified in the routing message to obtain an IP address to which the media relay should send audio/video and the remainder of the process mentioned above for establishing IP addresses at the media relay **9** and the caller telephone is carried out to establish audio/video paths to allowing the caller to leave a voicemail message with the voicemail server.
- (151) When an audio/video path through the media relay is established, a call timer maintained by the call controller **14** logs the start date and time of the call and logs the call ID and an identification of the route (i.e., audio/video path IP address) for later use in billing. (152) Time to Live
- (153) Referring to FIGS. **33**A and **33**B, a process for determining a time to live value for any of blocks **642** in FIG. **8**C, **350** in FIG. **8**A or **564** in FIG. **8**D above is described. The process is executed by the processor **202** shown in FIG. **7**. Generally, the process involves calculating a cost per unit time, calculating a first time value as a sum of a free time attributed to a participant in the communication session and the quotient of a funds balance held by the participant to the cost per unit time value and producing a second time value in response to the first time value and a billing pattern associated with the participant, the billing pattern including first and second billing intervals and the second time value being the time to permit a communication session to be conducted. (154) Referring to FIG. **33**A, in this embodiment, the process begins with a first block **700** that

directs the RC processor to determine whether or not the call type set at block **302** in FIG. **8**A indicates the call is a network or cross-domain call. If the call is a network or cross-domain call, block **702** of FIG. **33**A directs the RC processor to set the time to live equal to 99999 and the process is ended. Thus, the network or cross-domain call type has a long time to live. If at block **700** the call type is determined not to be a network or cross-domain type, block **704** directs the RC processor to get a subscriber bundle table record from the database **18** in FIG. **1** and store it locally in the subscriber bundle record buffer at the RC **14**.

- (155) Referring to FIG. **34**, a subscriber bundle table record is shown generally at **706**. The record includes a user name field **708** and a services field **710**. The user name field **708** holds a code identifying the subscriber user name and the services field **710** holds codes identifying service features assigned to the subscriber, such as free local calling, call blocking and voicemail, for example.
- (156) FIG. **35** shows an exemplary subscriber bundle record for the Vancouver caller. In this record the user name field **708** is loaded with the user name 2001 1050 8667 and the services field **710** is loaded with codes **10**, **14** and **16** corresponding to free local calling, call blocking and voicemail, respectively. Thus, user 2001 1050 8667 has free local calling, call blocking and voicemail features.
- (157) Referring back to FIG. **33**A, after having loaded a subscriber bundle record into the subscriber bundle record buffer, block **712** directs the RC processor to search the database (**18**) determine whether or not there is a bundle override table record for the master list ID value that was determined at block **410** in FIG. **8**B. An exemplary bundle override table record is shown at **714** in FIG. **36**. The bundle table record includes a master list ID field **716**, an override type field **718**, an override value field **720** a first interval field **722** and a second interval field **724**. The master list ID field **716** holds a master list ID code. The override type field **718** holds an override type code indicating a fixed, percent or cent amount to indicate the amount by which a fee will be increased. The override value field **720** holds a real number representing the value of the override type. The first interval field **722** holds a value indicating the minimum number of seconds for a first level of charging and the second interval field **724** holds a number representing a second level of charging.
- (158) Referring to FIG. 37, a bundle override record for the located master list ID code is shown generally at 726 and includes a master list ID field 716 holding the code 1019 which was the code located in block 410 of FIG. 8B. The override type field 718 includes a code indicating the override type is a percentage value and the override value field 720 holds the value 10.0 indicating that the override will be 10.0% of the charged value. The first interval field 722 holds a value representing 30 seconds and the second interval field 724 holds a value representing 6 seconds. The 30 second value in the first interval field 722 indicates that charges for the route will be made at a first rate for 30 seconds and thereafter the charges will be made at a different rate in increments of 6 seconds, as indicated by the contents of the second interval field 724.
- (159) Referring back to FIG. **33**A, if at block **712** the processor finds a bundle override record of the type shown in FIG. **37**, block **728** directs the processor to store the bundle override record in local memory. In the embodiment shown, the bundle override record shown in FIG. **37** is stored in the bundle override record buffer at the RC as shown in FIG. **7**. Still referring to FIG. **33**A, block **730** then directs the RC processor to determine whether or not the subscriber bundle table record **706** in FIG. **35** has a services field including a code identifying that the user is entitled to free local calling and also directs the processor to determine whether or not the call type is not a cross domain cell, i.e. it is a local or local/national style. If both of these conditions are satisfied, block **732** directs the processor to set the time to live equal to 99999, giving the user a long period of time for the call. The process is then ended. If the conditions associated with block **730** are not satisfied, block **734** of FIG. **33**B directs the RC processor to retrieve a subscriber account record associated with a participant in the call. This is done by copying and storing in the subscriber account record

buffer a subscriber account record for the caller.

(160) Referring to FIG. **38**, an exemplary subscriber account table record is shown generally at **736**. The record includes a user name field **738**, a funds balance field **740** and a free time field **742**. The user name field **738** holds a subscriber user name, the funds balance field **740** holds a real number representing the dollar value of credit available to the subscriber and the free time field **742** holds an integer representing the number of free seconds that the user is entitled to.

- (161) An exemplary subscriber account record for the Vancouver caller is shown generally at **744** in FIG. **39**, wherein the user name field **738** holds the user name 2001 1050 8667, the funds balance field **740** holds the value \$10.00, and the free time field **742** holds the value 100. The funds balance field holding the value of \$10.00 indicates the user has \$10.00 worth of credit and the free time field having the value of 100 indicates that the user has a balance of 100 free seconds of call time.
- (162) Referring back to FIG. 33B, after copying and storing the subscriber account record shown in FIG. 39 from the database to the subscriber account record buffer RC, block 746 directs the processor to determine whether or not the subscriber account record funds balance field 740 or free time field 742 are greater than zero. If they are not greater than zero, block 748 directs the processor to set the time to live equal to zero and the process is ended. The RC then sends a message back to the call controller to cause the call controller to deny the call to the caller. If the conditions associated with block 746 are satisfied, block 750 directs the processor to calculate the call cost per unit time. A procedure for calculating the call cost per unit time is described below in connection with FIG. 41.
- (163) Assuming the procedure for calculating the cost per second returns a number representing the call cost per second, block **752** directs the processor **202** in FIG. **7** to determine whether or not the cost per second is equal to zero. If so, block **754** directs the processor to set the time to live to 99999 to give the caller a very long length of call and the process is ended.
- (164) If at block **752** the call cost per second is not equal to zero, block **756** directs the processor **202** in FIG. 7 to calculate a first time to live value as a sum of a free time attributed to the participant in the communication session and the quotient of the funds balance held by the participant to the cost per unit time value. To do this, the processor **202** of FIG. **7** is directed to set a first time value or temporary time to live value equal to the sum of the free time provided in the free time field **742** of the subscriber account record shown in FIG. **39** and the quotient of the contents of the funds balance field **740** in the subscriber account record for the call shown in FIG. **39** and the cost per second determined at block **750** of FIG. **33**B. Thus, for example, if at block **750** the cost per second is determined to be three cents per second and the funds balance field holds the value \$10.00, the quotient of the funds balance and cost per second is 333 seconds and this is added to the contents of the free time field **742**, which is 100, resulting in a time to live of 433 seconds. (165) Block **758** then directs the RC processor to produce a second time value in response to the first time value and the billing pattern associated with the participant as established by the bundle override record shown in FIG. 37. This process is shown in greater detail at 760 in FIG. 40 and generally involves producing a remainder value representing a portion of the second billing interval remaining after dividing the second billing interval into a difference between the first time value and the first billing interval.
- (166) Referring to FIG. **40**, the process for producing the second time value begins with a first block **762** that directs the processor **202** in FIG. **7** to set a remainder value equal to the difference between the time to live value calculated at block **756** in FIG. **33**B and the contents of the first interval field **722** of the record shown in FIG. **37**, multiplied by the modulus of the contents of the second interval field **724** of FIG. **37**. Thus, in the example given, the difference between the time to live field and the first interval field is 433 minus 30, which is 403 and therefore the remainder produced by the mod of 403 divided by 6 is 0.17. Block **764** then directs the processor to determine whether or not this remainder value is greater than zero and, if so, block **766** directs the processor

to subtract the remainder from the first time value and set the difference as the second time value. To do this the processor is directed to set the time to live value equal to the current time to live of 403 minus the remainder of 1, i.e., 402 seconds. The processor is then returned back to block **758** of FIG. **33**B.

- (167) Referring back to FIG. **40**, if at block **764** the remainder is not greater than zero, block **768** directs the processor **202** of FIG. **7** to determine whether or not the time to live is less than the contents of the first interval field **722** in the record shown in FIG. **37**. If so, then block **770** of FIG. **40** directs the processor to set the time to live equal to zero. Thus, the second time value is set to zero when the remainder is greater than zero and the first time value is less than the free time associated with the participant in the call. If at block **768** the conditions of that block are not satisfied, the processor returns the first time to live value as the second time to live value. (168) Thus, referring to FIG. **33**B, after having produced a second time to live value, block **772** directs the processor to set the time to live value for use in blocks **342**, **350** or **564**. (169) Cost Per Second
- (170) Referring back to FIG. 33B, at block 750 it was explained that a call cost per unit time is calculated. The following explains how that call cost per unit time value is calculated. (171) Referring to FIG. 41, a process for calculating a cost per unit time is shown generally at 780. The process is executed by the processor 202 in FIG. 7 and generally involves locating a record in a database, the record comprising a markup type indicator, a markup value and a billing pattern and setting a reseller rate equal to the sum of the markup value and the buffer rate, locating at least one of an override record specifying a route cost per unit time amount associated with a route associated with the communication session, a reseller record associated with a reseller of the communications session, the reseller record specifying a reseller cost per unit time associated with the reseller for the communication session and a default operator markup record specifying a default cost per unit time and setting as the cost per unit time the sum of the reseller rate and at least one of the route cost per unit time, the reseller cost per unit time and the default cost per unit time.
- (172) The process begins with a first set of blocks **782**, **802** and **820** which direct the processor **202** in FIG. **7** to locate at least one of a record associated with a reseller and a route associated with the reseller, a record associated with the reseller, and a default reseller mark-up record. Block **782**, in particular, directs the processor to address the database **18** to look for a record associated with a reseller and a route with the reseller by looking for a special rate record based on the master list ID established at block **410** in FIG. **8**C.
- (173) Referring to FIG. **42**, a system operator special rate table record is shown generally at **784**. The record includes a reseller field **786**, a master list ID field **788**, a mark-up type field **790**, a mark-up value field **792**, a first interval field **794** and a second interval field **796**. The reseller field **786** holds a reseller ID code and the master list ID field **788** holds a master list ID code. The mark-up type field **790** holds a mark-up type such as fixed percent or cents and the mark-up value field **792** holds a real number representing the value corresponding to the mark-up type. The first interval field **794** holds a number representing a first level of charging and the second interval field **796** holds a number representing a second level of charging.
- (174) An exemplary system operator special rate table for a reseller known as "Klondike" is shown at **798** in FIG. **43**. In this record, the reseller field **786** holds a code indicating the retailer ID is Klondike, the master list ID field **788** holds the code 1019 to associate the record with the master list ID code 1019. The mark-up type field **790** holds a code indicating the mark-up type is cents and the mark-up value field **792** holds a mark-up value indicating 1/10 of one cent. The first interval field **794** holds the value 30 and the second interval field **796** holds the value 6, these two fields indicating that the operator allows 30 seconds for free and then billing is done in increments of 6 seconds after that.
- (175) Referring back to FIG. 41, if at block 782 a record such as the one shown in FIG. 43 is

located in the system operator special rates table, the processor is directed to block **800** in FIG. **41**. If such a record is not found in the system operator special rates table, block **802** directs the processor to address the database **18** to look in a system operator mark-up table for a mark-up record associated with the reseller.

- (176) Referring to FIG. **44**, an exemplary system operator mark-up table record is shown generally at **804**. The record includes a reseller field **806**, a mark-up type field **808**, a mark-up value field **810**, a first interval field **812** and a second interval field **814**. The reseller mark-up type, mark-up value, first interval and second interval fields are as described in connection with the fields by the same names in the system operator special rates table shown in FIG. **42**.
- (177) FIG. **45** provides an exemplary system operator mark-up table record for the reseller known as Klondike and therefore the reseller field **806** holds the value "Klondike", the mark-up type field **808** holds the value cents, the mark-up value field holds the value 0.01, the first interval field **812** holds the value 30 and the second interval field 814 holds the value 6. This indicates that the reseller "Klondike" charges by the cent at a rate of one cent per minute. The first 30 seconds of the call are free and billing is charged at the rate of one cent per minute in increments of 6 seconds. (178) FIG. **46** provides an exemplary system operator mark-up table record for cases where no specific system operator mark-up table record exists for a particular reseller, i.e., a default reseller mark-up record. This record is similar to the record shown in FIG. 45 and the reseller field 806 holds the value "all", the mark-up type field **808** is loaded with a code indicating mark-up is based on a percentage, the mark-up value field **810** holds the percentage by which the cost is marked up, and the first and second interval fields **812** and **814** identify first and second billing levels. (179) Referring back to FIG. **41**, if at block **802** a specific mark-up record for the reseller identified at block **782** is not located, block **820** directs the processor to get the mark-up record shown in FIG. **46**, having the "all" code in the reseller field **806**. The processor is then directed to block **800**. (180) Referring back to FIG. **41**, at block **800**, the processor **202** of FIG. **7** is directed to set a reseller rate equal to the sum of the mark-up value of the record located by blocks 782, 802 or 820 and the buffer rate specified by the contents of the buffer rate field 516 of the master list record shown in FIG. **20**. To do this, the RC processor sets a variable entitled "reseller cost per second" to a value equal to the sum of the contents of the mark-up value field (792, 810) of the associated record, plus the contents of the buffer rate field (516) from the master list record associated with the master list ID. Then, block **822** directs the processor to set a system operator cost per second variable equal to the contents of the buffer rate field (516) from the master list record. Block 824 then directs the processor to determine whether the call type flag indicates the call is local or national/local style and whether the caller has free local calling. If both these conditions are met, then block **826** sets the user cost per second variable equal to zero and sets two increment variables equal to one, for use in later processing. The cost per second has thus be calculated and the process shown in FIG. 41 is ended.
- (181) If at block **824** the conditions of that block are not met, the processor **202** of FIG. **7** is directed to locate at least one of a bundle override table record specifying a route cost per unit time associated with a route associated with the communication session, a reseller special destinations table record associated with a reseller of the communications session, the reseller record specifying a reseller cost per unit time associated with the reseller for the communication session and a default reseller global markup record specifying a default cost per unit time.
- (182) To do this block **828** directs the processor **202** of FIG. **7** to determine whether or not the bundle override record **726** in FIG. **37** located at block **712** in FIG. **33**A has a master list ID equal to the stored master list ID that was determined at block **410** in FIG. **8**B. If not, block **830** directs the processor to find a reseller special destinations table record in a reseller special destinations table in the database (**18**), having a master list ID code equal to the master list ID code of the master list ID that was determined at block **410** in FIG. **8**B. An exemplary reseller special destinations table record is shown in FIG. **47** at **832**. The reseller special destinations table record

includes a reseller field **834**, a master list ID field **836**, a mark-up type field **838**, a mark-up value field **840**, a first interval field **842** and a second interval field **844**. This record has the same format as the system operator special rates table record shown in FIG. **42**, but is stored in a different table to allow for different mark-up types and values and time intervals to be set according to resellers' preferences. Thus, for example, an exemplary reseller special destinations table record for the reseller "Klondike" is shown at **846** in FIG. **48**. The reseller field **834** holds a value indicating the reseller as the reseller "Klondike" and the master list ID field holds the code 1019. The mark-up type field **838** holds a code indicating the mark-up type is percent and the mark-up value field **840** holds a number representing the mark-up value as 5%. The first and second interval fields identify different billing levels used as described earlier.

- (183) Referring back to FIG. **41**, the record shown in FIG. **48** may be located at block **830**, for example. If at block **830** such a record is not found, then block **832** directs the processor to get a default operator global mark-up record based on the reseller ID.
- (184) Referring to FIG. **49**, an exemplary default reseller global mark-up table record is shown generally at **848**. This record includes a reseller field **850**, a mark-up type field **852**, a mark-up value field **854**, a first interval field **856** and a second interval field **858**. The reseller field **850** holds a code identifying the reseller. The mark-up type field **852**, the mark-up value field **854** and the first and second interval fields **856** and **858** are of the same type as described in connection with fields of the same name in FIG. **47**, for example. The contents of the fields of this record **860** may be set according to system operator preferences, for example.
- (185) Referring to FIG. **50**, an exemplary reseller global mark-up table record is shown generally at **860**. In this record, the reseller field **850** holds a code indicating the reseller is "Klondike", the mark-up type field **852** holds a code indicating the mark-up type is percent, the mark-up value field **854** holds a value representing 10% as the mark-up value, the first interval field **856** holds the value 30 and the second interval field **858** holds the values 30 and 6 respectively to indicate the first 30 seconds are free and billing is to be done in 6 second increments after that.

 (186) Referring back to FIG. **41**, should the processor get to block **832**, the reseller global mark-up
- table record as shown in FIG. **50** is retrieved from the database and stored locally at the RC. As seen in FIG. **41**, it will be appreciated that if the conditions are met in blocks **828** or **830**, or if the processor executes block **832**, the processor is then directed to block **862** which causes it to set an override value equal to the contents of the mark-up value field of the located record, to set the first increment variable equal to the contents of the first interval field of the located record and to set the second increment variable equal to the contents of the second interval field of the located record. (The increment variables were alternatively set to specific values at block **826** in FIG. **41**.)
- (187) It will be appreciated that the located record could be a bundle override record of the type shown in FIG. **37** or the located record could be a reseller special destination record of the type shown in FIG. **48** or the record could be a reseller global mark-up table record of the type shown in FIG. **50**. After the override and first and second increment variables have been set at block **862**, the processor **202** if FIG. **7** is directed to set as the cost per unit time the sum of the reseller rate and at least one of the route cost per unit time, the reseller cost per unit time and the default cost per unit time, depending on which record was located. To do this, block **864** directs the processor to set the cost per unit time equal to the sum of the reseller cost set at block **800** in FIG. **41**, plus the contents of the override variable calculated in block **862** in FIG. **41**. The cost per unit time has thus been calculated and it is this cost per unit time that is used in block **752** of FIG. **33**B, for example. (188) Terminating the Call
- (189) In the event that either the caller or the callee terminates a call, the telephone of the terminating party sends a SIP bye message to the controller **14**. An exemplary SIP bye message is shown at **900** in FIG. **51** and includes a caller field **902**, a callee field **904** and a call ID field **906**. The caller field **902** holds a twelve digit user name, the callee field **904** holds a PSTN compatible number or user name, and the call ID field **906** holds a unique call identifier field of the type shown

in the call ID field **65** of the SIP invite message shown in FIG. **3**.

(190) Thus, for example, referring to FIG. **52**, a SIP bye message for the Calgary callee is shown generally at **908** and the caller field **902** holds a user name identifying the caller, in this case 2001 1050 8667, the callee field **904** holds a user name identifying the Calgary callee, in this case 2001 1050 2222, and the call ID field **906** holds the code FA10 @ 192.168.0.20, which is the call ID for the call.

(191) The SIP bye message shown in FIG. **52** is received at the call controller **14** and the call

- controller executes a process as shown generally at 910 in FIG. 53. The process includes a first block **912** that directs the call controller processor **202** of FIG. 7 to copy the caller, callee and call ID field contents from the SIP by emessage received from the terminating party to corresponding fields of an RC stop message buffer (not shown). Block **914** then directs the processor to copy the call start time from the call timer and to obtain a call stop time from the call timer. Block **916** then directs the call controller to calculate a communication session time by determining the difference in time between the call start time and the call stop time. This session time is then stored in a corresponding field of the RC call stop message buffer. Block 917 then directs the processor to decrement the contents of the current concurrent call field 277 of the dialing profile for the caller as shown in FIG. 10, to indicate that there is one less concurrent call in progress. A copy of the amended dialing profile for the caller is then stored in the database **18** of FIG. **1**. Block **918** then directs the processor to copy the route from the call log. An RC call stop message produced as described above is shown generally at **1000** in FIG. **54**. An RC call stop message specifically associated with the call made to the Calgary callee is shown generally at **1020** in FIG. **55**. (192) Referring to FIG. **54**, the RC stop call message includes a caller field **1002**, callee field **1004**, a call ID field 1006, an account start time field 1008, an account stop time field 1010, a communication session time **1012** and a route field **1014**. The caller field **1002** holds a username, the callee field **1004** holds a PSTN-compatible number or system number, the call ID field **1006** hold the unique call identifier received from the SIP invite message shown in FIG. **3**, the account start time field **1008** holds the date and start time of the call, the account stop time field **1010** holds the date and time the call ended, the communication session time field 1012 holds a value representing the difference between the start time and the stop time, in seconds, and the route field **1014** holds the IP address for the communications link that was established. (193) Referring to FIG. 55, an exemplary RC stop call message for the Calgary callee is shown generally at **1020**. In this example the caller field **1002** holds the user name 2001 1050 8667 identifying the Vancouver-based caller and the callee field **1004** holds the user name 2001 1050
- 2222 identifying the Calgary callee. The contents of the call ID field **1006** are FA10@ 192.168.0.20. The contents of the account start time field **1008** are 2006-12-30 12:12:12 and the contents of the account stop time field are 2006-12-30 12:12:14. The contents of the communication session time field **1012** are 2 to indicate 2 seconds call duration and the contents of the route field are 72.64.39.58.
- (194) Referring back to FIG. **53**, after having produced an RC call stop message, block **920** directs the processor **202** in FIG. **7** to send the RC stop message compiled in the RC call stop message buffer to the RC **16** of FIG. **1**. Block **922** directs the call controller **14** to send a "bye" message back to the party that did not terminate the call.
- (195) The RC **16** of FIG. **1** receives the call stop message and an RC call stop message process is invoked at the RC, the process being shown at **950** in FIGS. **56**A, **56**B and **56**C. Referring to FIG. **56**A, the RC stop message process **950** begins with a first block **952** that directs the processor **202** in FIG. **7** to determine whether or not the communication session time is less than or equal to the first increment value set by the cost calculation routine shown in FIG. **41**, specifically blocks **826** or **862** thereof. If this condition is met, then block **954** of FIG. **56**A directs the RC processor to set a chargeable time variable equal to the first increment value set at block **826** or **862** of FIG. **41**. If at block **952** of FIG. **56**A the condition is not met, block **956** directs the RC processor to set a

remainder variable equal to the difference between the communication session time and the first increment value mod the second increment value produced at block **826** or **862** of FIG. **41**. Then, the processor is directed to block **958** of FIG. **56**A which directs it to determine whether or not the remainder is greater than zero. If so, block **960** directs the RC processor to set the chargeable time variable equal to the difference between the communication session time and the remainder value. If at block **958** the remainder is not greater than zero, block **962** directs the RC processor to set the chargeable time variable equal to the contents of the communication session time from the RC stop message. The processor is then directed to block **964**. In addition, after executing block **954** or block **960**, the processor is directed to block **964**.

- (196) Block **964** directs the processor **202** of FIG. **7** to determine whether or not the chargeable time variable is greater than or equal to the free time balance as determined from the free time field **742** of the subscriber account record shown in FIG. **39**. If this condition is satisfied, block **966** of FIG. **56**A directs the processor to set the free time field **742** in the record shown in FIG. **39**, to zero. If the chargeable time variable is not greater than or equal to the free time balance, block **968** directs the RC processor to set a user cost variable to zero and Block **970** then decrements the free time field **742** of the subscriber account record for the caller by the chargeable time amount determined by block **954**, **960** or **962**.
- (197) If at Block **964** the processor **202** of FIG. **7** was directed to Block **966** which causes the free time field (**742** of FIG. **39**) to be set to zero, referring to FIG. **56**B, Block **972** directs the processor to set a remaining chargeable time variable equal to the difference between the chargeable time and the contents of the free time field (**742** of FIG. **39**). Block **974** then directs the processor to set the user cost variable equal to the product of the remaining chargeable time and the cost per second calculated at Block **750** in FIG. **33**B. Block **976** then directs the processor to decrement the funds balance field (**740**) of the subscriber account record shown in FIG. **39** by the contents of the user cost variable calculated at Block **974**.
- (198) After completing Block **976** or after completing Block **970** in FIG. **56**A, block **978** of FIG. **56**B directs the processor **202** of FIG. **7** to calculate a reseller cost variable as the product of the reseller rate as indicated in the mark-up value field **810** of the system operator mark-up table record shown in FIG. **45** and the communication session time determined at Block **916** in FIG. **53**. Then, Block **980** of FIG. **56**B directs the processor to add the reseller cost to the reseller balance field **986** of a reseller account record of the type shown in FIG. **57** at **982**.
- (199) The reseller account record includes a reseller ID field **984** and the aforementioned reseller balance field **986**. The reseller ID field **984** holds a reseller ID code, and the reseller balance field **986** holds an accumulated balance of charges.
- (200) Referring to FIG. **58**, a specific reseller accounts record for the reseller "Klondike" is shown generally at **988**. In this record the reseller ID field **984** holds a code representing the reseller "Klondike" and the reseller balance field **986** holds a balance of \$100.02. Thus, the contents of the reseller balance field **986** in FIG. **58** are incremented by the reseller cost calculated at block **978** of FIG. **56**B.
- (201) Still referring to FIG. **56**B, after adding the reseller cost to the reseller balance field as indicated by Block **980**, Block **990** directs the processor to **202** of FIG. **7** calculate a system operator cost as the product of the system operator cost per second, as set at block **822** in FIG. **41**, and the communication session time as determined at Block **916** in FIG. **53**. Block **992** then directs the processor to add the system operator cost value calculated at Block **990** to a system operator accounts table record of the type shown at **994** in FIG. **59**. This record includes a system operator balance field **996** holding an accumulated charges balance. Referring to FIG. **60** in the embodiment described, the system operator balance field **996** may hold the value \$1,000.02 for example, and to this value the system operator cost calculated at Block **990** is added when the processor executes Block **992** of FIG. **56**B.
- (202) Ultimately, the final reseller balance 986 in FIG. 58 holds a number representing an amount

owed to the reseller by the system operator and the system operator balance **996** of FIG. **59** holds a number representing an amount of profit for the system operator.

(203) While specific embodiments of the invention have been described and illustrated, such embodiments should be considered illustrative of the invention only and not as limiting the invention as construed in accordance with the accompanying claims.

Claims

- 1. A method for routing a communication in a communication system between a first participant device, on an Internet Protocol (IP) network, associated with a first participant, and a second participant device associated with a second participant, the method comprising: in response to initiation of the communication by the first participant device, receiving, by at least one processor, a second participant identifier associated with the second participant device; causing the at least one processor to access a user profile that is specific to the first participant and stored in at least one memory, the user profile being associated with a plurality of first participant attributes; comparing at least a portion of the second participant identifier with at least one of the plurality of first participant attributes associated with the user profile of the first participant, using the at least one processor and identifying whether at least one route exists whereby the communication may be routed to the second participant device; when the at least one route is associated with a first communication network, producing a message comprising route information identifying an Internet Protocol (IP) address, on the first communication network, associated with the second participant device, using the at least one processor, and causing the communication to be established to the second participant device using the first communication network; and when the at least one route is associated with a second communication network, producing message comprising route information identifying an Internet Protocol (IP) address associated with a gateway to the second communication network, using the at least one processor, and causing the communication to the second participant device to be established using the gateway to the second communication network.
- 2. The method of claim 1, wherein: the first communication network is an Internet protocol (IP) network; and the second communication network is a switched circuit network, and wherein the method further comprises: producing a device identifier representing a communication device on one of the first communication network or the second communication network; and causing a database of subscribers to be searched to identify whether the device identifier is associated with a subscriber of the first network, wherein: if the device identifier is found in the database of subscribers, causing the Internet Protocol (IP) address to identify a network element on the first communication network; and if the device identifier is not found in the database of subscribers, causing the Internet Protocol (IP) address to identify the gateway to the second communication network.
- 3. The method of claim 2, wherein the Internet address, on the first communication network, associated with the second participant device comprises an address of a communication system node associated with the second participant device, the communication system node being one of a plurality of communication system nodes each operably configured to provide communications services to a plurality of communication system subscribers.
- 4. The method of claim 3 further comprising determining whether the first participant device and the second participant device are associated with the same communication system node, and if so, selecting the at least one route to carry the communication to the second participant device using the first communication network.
- 5. The method of claim 2, further comprising: accessing at least one database to locate communication blocking information associated with the second participant, using the at least one processor; and blocking the communication when the communication blocking information

associated with the second participant identifies the first participant identifier.

- 6. The method of claim 2, further comprising: accessing at least one database to locate communication forwarding information associated with the second participant, using the at least one processor; and forwarding the communication to at least one destination communication device based on the communication forwarding information.
- 7. The method of claim 6, wherein the communication forwarding information for the second participant comprises identifiers for a plurality of destination communication devices.
- 8. The method of claim 2, further comprising: processing a plurality of communications from the first participant device to a plurality of destination communication devices to identify respective available routes associated with establishing each of the plurality of communications as a first network communication or a second network communication; and producing a respective plurality of messages, each respective message comprising route information identifying an IP address, on the first communication network, associated with a respective communication device or identifying an IP address associated with a gateway to the second communication network; wherein each message causes the respective communication to be established to the respective destination communication device based on the identified respective available route.
- 9. The method of claim 1, further comprising: (a) processing a plurality of communication device identifiers produced by comparing a plurality of participant identifiers with the user profile for the first participant, to determine whether each respective communication device identifier is associated with a subscriber to the communication system, wherein: (i) when the respective communication device identifier is associated with a subscriber to the communication system, producing a respective message comprising route information identifying an address, on the first communication network, associated with the second participant device; and (ii) when the respective communication device identifier is not associated with a subscriber to the communication system, producing a respective message comprising route information identifying an address of a gateway to the second communication network; and (b) establishing communications to communication devices respectively associated with the plurality of communication device identifiers in response to each of the respective messages.
- 10. The method of claim 9 further comprising identifying the at least one route by determining whether the second participant identifier corresponds to a pre-defined username format, and if so, causing the route information in the message to identify a network element in the first communication network operable to carry the communication to the second participant device using the first communication network.
- 11. The method of claim 9 further comprising querying a plurality of gateways regarding whether each of the gateways is able to handle the communication until at least one gateway from the plurality of gateways indicates that it is available to carry the communication, and establishing the communication to the second participant device using at least one IP address associated with the gateway that indicates that it is available to carry the communication.
- 12. The method of claim 9 further comprising, if the second participant device does not receive the communication in response to initiation of the communication, storing the communication on a server in association with the second participant identifier to facilitate the second participant device retrieving the communication from the server.
- 13. The method of claim 1, further comprising identifying the at least one route by causing a database of records to be searched to locate a Direct-Inward-Dial (DID) record associating a public telephone number with said second participant device; and if said DID record is found, selecting the at least one route to carry the communication to the second participant device using the first communication network and if said DID record is not found, selecting the at least one route to carry the communication to the second participant device using the second communication network.

 14. The method of claim 1 further comprising: (a) identifying route information representing a
- 14. The method of claim 1 further comprising: (a) identifying route information representing a plurality of possible paths for routing the communication from the first participant device to the

second participant device; (b) processing a routing cost associated with each of the plurality of possible paths for routing the communication; and (c) producing a routing message comprising at least some of the route information and a time to live for the communication, based on the step of processing the routing cost.

- 15. The method of claim 1, further comprising: processing at least one user-specific first participant attribute, using the at least one processor, to determine whether a further communication that was initiated by the first participant to a third participant device is allowed to proceed; if the at least one processor determines that the further communication is not allowed to proceed based on the at least one user-specific first participant attribute, preventing the further communication from being established; if the further communication is allowed to proceed, causing a database of subscribers to be searched to identify a device identifier associated with the second participant device, wherein if a registration of the device identifier in the database of subscribers is found, causing the Internet Protocol (IP) address to identify a network element on the first communication network, and if the registration in the database of subscribers is not found, causing the Internet Protocol (IP) address to identify the gateway to the second communication network.
- 16. The method of claim 15, wherein: if the further communication is allowed to proceed based on the userspecific first participant attribute, causing the at least one processor to search a database for communication blocking information associated with the third participant device, and if the communication blocking information is found, preventing the further communication from being established; and if the further communication is allowed to proceed based on the at least one userspecific first participant attribute and no communication blocking information associated with the third participant device is found in the database, causing the at least one processor to produce a corresponding message comprising route information to cause the further communication to be established to the third participant device; wherein the device identifier in the database of subscribers comprises at least one of a username and a Direct-Inward-Dial (DID) number.
- 17. A non-transitory computer readable medium encoded with instructions for directing at least one processor to execute the method of claim 15.
- 18. The method of claim 1, further comprising causing the at least one processor to: determine whether the user profile for the second participant exists in at least one database; and if the user profile for the second participant does not exist in the at least one database, cause the communication to be established to the second communication device via the second communication network.
- 19. The method of claim 18, further comprising causing the at least one processor to: if the user profile for the second participant exists in the at least one database, cause the communication to be established to the second communication device via the first communication network.
- 20. The method of claim 19 further comprising using information associated with the user profile for the second participant to identify at least one IP address of a network element capable of carrying the communication to the second participant device.
- 21. The method of claim 1 wherein the message comprising route information identifying an Internet Protocol (IP) address is produced in parts, and wherein at least one part of the message comprising route information causes the communication to be established.
- 22. The method of claim 21 further comprising collecting data comprising the route information in a buffer prior to causing the communication to be established.
- 23. The method of claim 1 wherein producing the message comprising route information identifying an Internet Protocol (IP) address comprises identifying a plurality of network element addresses representing a plurality of routes for routing the communication, and using at least one of the plurality of routes to cause the communication to be established.
- 24. The method of claim 1 wherein identifying whether at least one route exists comprises locating at least one Direct-Inward-Dial (DID) record associating a public telephone number of the second participant device with an identifier of a network element with which the second participant device

is currently associated, and causing the communication to be routed to the second participant device based on the identifier of the network element with which the second participant device is currently associated.

- 25. The method of claim 1 wherein identifying whether at least one route exists comprises causing at least one database to be searched to locate information associating a public telephone number of the second participant device with a user profile of the second participant that identifies a network elements with which the second participant device is currently associated, and causing the communication to be routed to the second participant device based on the identifier of the network element with which the second participant device is currently associated.
- 26. The method of claim 1 further comprising causing at least one database to be searched to locate information associating a public telephone number of the second participant device with an address of a network element with which the second participant device is currently associated, and sending the message comprising route information to the network element to facilitate the communication being routed to the second participant device.
- 27. A method for routing communications in a packet switched communication system between a first participant device associated with a first participant, and a second participant device associated with a second participant, the method comprising: in response a communication being initiated from the first participant device to the second participant device, receiving, by at least one processor, a second participant identifier associated with the second participant device; causing the at least one processor to load a plurality of first participant attributes obtained from a user profile for the first participant into at least one memory; comparing at least a portion of the second participant identifier with at least one of the plurality of first participant attributes obtained from the user profile for the first participant, using the at least one processor, to produce a device identifier for use in identifying availability of a route whereby the communication may be routed to the second participant device; identifying at least a portion of the route whereby the communication may be routed to the second participant device by causing a database of records to be searched to locate a Direct-Inward-Dial (DID) record associating a public telephone number with said second participant device, wherein if said DID record is found, identifying the at least one portion of the route to carry the communication to the second participant device using the first communication network, and wherein if said DID record is not found, identifying the at least portion of the route to carry the communication to the second participant device using the second communication network; causing a message to be produced comprising route information identifying an Internet Protocol (IP) address associated with the at least a portion of the route to cause the communication to be established to the second participant device, wherein the route information is associated with either the first communication network or the second communication network; wherein, when the at least a portion of the route is associated with the first communication network, the Internet Protocol (IP) address is used by a communication controller to cause the communication to be established to the second participant device using the first communication network; and wherein, when the at least a portion of the route is associated with a second communication network, the Internet Protocol (IP) address is used by the communication controller to cause the communication to be established to the second participant device through a gateway to the second communication network.
- 28. A system for routing a communication between a first participant device associated with a first participant, and a second participant device associated with a second participant, the system comprising: means for receiving a second participant identifier associated with the second participant device, in response to initiation of the communication by the first participant device; means for causing a user profile to be accessed in at least one memory, the user profile being specific to the first participant and associated with a plurality of first participant attributes; at least one processor for comparing at least a portion of the second participant identifier with at least one of the plurality of first participant attributes associated with the user profile of the first participant,

to produce a second participant device identifier or identify a username associated with the second participant; means for identifying at least one route to the second participant device, based on the second participant device identifier or username, whereby the communication may be routed to the second participant device on a first communication network or a second communication network, the means for identifying at least one route to the second participant device comprising at least one system subscriber database for identifying subscribers and at least one route database for providing route information comprising at least one of an Internet protocol (IP) address or domain name associated with the at least one route to the second participant device; and at least one server causing a message comprising the route information to be produced, the route information identifying the at least one route on the first communication network, associated with the second participant device, when the at least one route is associated with a subscriber of the system, the message comprising the route information causing the communication to be carried to the second participant device using the first communication network; and the at least one server causing a message comprising the route information to be produced identifying the at least one route to a gateway to the second communication network, when the at least one route is associated with a non-subscriber of the system, the message comprising the route information causing the communication to be carried to the second participant device using the gateway to the second communication network.

- 29. An apparatus for routing communications in a packet switched communication system between a first participant device associated with a first participant and a second participant device associated with a second participant, the apparatus comprising: at least one controller comprising at least one processor in communication with at least one memory storing processor readable instructions, the at least one processor being operably configured by the processor readable instructions to: in response to initiation of a communication to the second participant device, receive a second participant identifier; access at least one first participant profile in the at least one memory to locate at least one first participant attribute associated with the first participant; compare at least a portion of the second participant identifier with the at least one first participant attribute to identify a second participant device identifier associated with at least one route whereby the communication may be routed to the second participant device; and cause a message to be produced comprising route information, based on the second participant device identifier, said route information identifying an Internet Protocol (IP) address associated with the at least a portion of the route to cause the communication to be established to the second participant device; when the at least a portion of the route is associated with a first communication network, causing the Internet Protocol (IP) address to identify a network element on the first communication network to establish the communication to the second participant device; and when the at least a portion of the route is associated with a second communication network, causing the Internet Protocol (IP) address to identify a gateway to the second communication network to establish the communication to the second participant device.
- 30. The apparatus of claim 29 wherein: the first communication network is an Internet protocol (IP) network; and the second communication network is a Public Switched Telephone Network (PSTN), and the at least one processor executes instructions to cause a database of records to be searched to locate a Direct-Inward-Dial (DID) record associating a public telephone number with said second participant device, wherein: if said DID record is found, causing the Internet Protocol (IP) address to identify the network element on the first communication network to carry the communication to the second participant device using the first communication network; and if said DID record is not found, causing the Internet Protocol (IP) address to identify the gateway to the second communication network to carry the communication to the second participant device using the second communication network.
- 31. The apparatus of claim 30, wherein the at least one processor is configured to: access at least one database to locate communication blocking information associated with the second participant;

- and block the communication when the communication blocking information associated with the second participant identifies the first participant.
- 32. The apparatus of claim 30, wherein the at least one processor is configured to identify forwarding information associated with the communication, the forwarding information identifying a plurality of destination communication devices.
- 33. The apparatus of claim 30 wherein the at least one processor is configured to: (a) identify a plurality of Internet Protocol (IP) addresses for routing the communication to the second participant device; and (b) causing the communication to be received at one of the plurality of Internet Protocol (IP) addresses for routing the communication.
- 34. The apparatus of claim 29, wherein the at least one processor is further operably configured to: (a) in response to initiation of a further communication to a third participant device, receive a third participant identifier associated with the third participant device; (b) process an attribute associated with the first participant profile to determine whether the further communication is allowed to proceed; (c) if the further communication is not allowed to proceed, cause the further communication not to be established to the third participant device; (d) if the further communication is allowed to proceed, causing a database of subscribers to be searched to identify a subscriber device identifier, wherein if an entry associated with the subscriber device identifier is found in the database of subscribers, causing the Internet Protocol (IP) address to identify a network element on the first communication network, and if an entry associated with the subscriber device identifier is not found, causing the Internet Protocol (IP) address to identify the gateway to the second communication network.
- 35. The apparatus of claim 34 wherein the at least one processor is further operably configured to: cause a query to be sent to a plurality of gateways to determine whether at least one gateway from the plurality of gateways is available to carry the further communication to the third participant device.
- 36. The apparatus of claim 34 wherein the at least one processor is further operably configured to: cause the further communication to be routed to a server operable to store the further communication to facilitate delivery of the communication to the third participant device at a later time.
- 37. The apparatus of claim 29 wherein the at least one processor is operably configured by the processor readable instructions to: cause at least one database to be searched to locate information associating a public telephone number of the second participant device with an identifier of a network element with which the second participant device is currently associated, and causing the communication to be routed to the second participant device based on the identifier of the network element with which the second participant device is currently associated.
- 38. The apparatus of claim 37 wherein the at least one database comprises a Direct-Inward-Dial (DID) database associating the public telephone number of the second participant device with an identifier of the network element, wherein the network element facilitates routing of the communication to the second participant device.
- 39. The apparatus of claim 29 wherein the at least one processor is operably configured by the processor readable instructions to: cause at least one database to be searched to locate information associating a public telephone number of the second participant device with a user profile of the second participant that identifies a network element with which the second participant device is currently associated, and causing the communication to be routed to the second participant device based on the identifier of the network element with which the second participant device is currently associated.
- 40. The apparatus of claim 39 wherein the at least one database comprises a Direct-Inward-Dial (DID) database associating the public telephone number of the second participant device with an identifier of the network element, wherein the network element facilitates routing of the communication to the second participant device.
