PEN STATE DETECTION CIRCUIT AND METHOD INHIBITING UNEXPECTED RESULTS FROM PERIPHERY OF TOUCH SENSOR

Abstract

A pen state detection circuit that is connected to a touch sensor of a capacitance type and adapted to detect a state of an electronic pen in accordance with an output signal from the touch sensor. The touch sensor includes sensor electrodes disposed in a planar manner, and the electronic pen includes a first electrode and a second electrode. The pen state detection circuit includes a processor configured to sequentially and repeatedly: acquire first and second coordinate values in a sensor coordinate system, the coordinate system being defined on a detection surface of the touch sensor, the first coordinate values indicating a projected position of the first electrode, the second coordinate values indicating a projected position of the second electrode; calculate an inclination value indicative of an inclination of the electronic pen from the acquired first and second coordinate values in accordance with calculation rules; and output the inclination value.

Background/Summary

BACKGROUND
Technical Field
[0001] The present disclosure relates to a pen state detection circuit and a pen state detection method.
Background Art
[0002] An electronic device disclosed in Japanese Patent Laid-open No. 2015-087785 detects a first position, which is a position on a detection surface of a touch sensor that is touched by a hand of a user, detects a second position, which is a position indicated by an electronic pen, estimates a direction of inclination of the electronic pen by using coordinate values of the first and second positions, and corrects the position indicated by the electronic pen in accordance with the estimated direction of inclination.
[0003] Incidentally, even in a case where the hand of the user is not in contact with the detection surface, a position and a posture of the electronic pen can be estimated by using an electronic pen having two electrodes. However, the two electrodes are disposed at a physical distance from each other. Therefore, there are some cases where, for example, at a periphery or a bend of the touch sensor, only a projected position of one electrode is not detected or a detected projected position is deviated from an actual projected position. Consequently, unexpected calculation results regarding the state of the electronic pen are outputted.
BRIEF SUMMARY
[0004] The present disclosure has been made in view of the above circumstances, and provides a pen state detection circuit and a pen state detection method that make it possible to inhibit unexpected results from being obtained from a periphery or a bend of a touch sensor when the inclination of an electronic pen having two electrodes is calculated.
[0005] According to a first aspect of the present disclosure, there is provided a pen state detection circuit that is connected to a touch sensor of a capacitance type and adapted to detect a state of an electronic pen in accordance with an output signal from the touch sensor, the touch sensor including a plurality of sensor electrodes disposed in a planar manner, the electronic pen including a first electrode and a second electrode, the pen state detection circuit including: a processor; and a memory storing instructions that, when executed by the processor, cause the pen state detection circuit to sequentially and repeatedly: acquire first coordinate values and second coordinate values in a sensor coordinate system, the coordinate system being defined on a detection surface of the touch sensor, the first coordinate values indicating a projected position of the first electrode, the second coordinate values indicating a projected position of the second electrode; calculate an inclination value indicative of an inclination of the electronic pen from the first coordinate values

and second coordinate values in accordance with calculation rules; and output the inclination value, in which, while the inclination value is sequentially and repeatedly calculated and outputted, an inclination value outputted when decision conditions are satisfied is different from an inclination value calculated in accordance with ordinary calculation rules when the decision conditions are not satisfied, the decision conditions representing a situation where at least one of the first and second electrodes is potentially in a position interfering with a periphery or a bend of the touch sensor as viewed from above the detection surface.

[0006] According to a second aspect of the present disclosure, there is provided a pen state detection method performed by a pen state detection circuit, the pen state detection circuit being connected to a touch sensor of a capacitance type and adapted to detect a state of an electronic pen in accordance with an output signal from the touch sensor, the touch sensor including a plurality of sensor electrodes disposed in a planar manner, the electronic pen including a first electrode and a second electrode, the method including sequentially and repeatedly: acquiring first coordinate values and second coordinate values in a sensor coordinate system, the coordinate system being defined on a detection surface of the touch sensor, the first coordinate values indicating a projected position of the first electrode, the second coordinate values indicating a projected position of the second electrode; calculating an inclination value indicative of an inclination of the electronic pen from the first coordinate values and second coordinate values in accordance with calculation rules; and outputting the inclination value, in the calculating and outputting, an inclination value outputted when decision conditions are satisfied being different from an inclination value that is calculated in accordance with ordinary calculation rules when the decision conditions are not satisfied, the decision conditions representing a situation where at least one of the first and second electrodes is potentially in a position interfering with a periphery or a bend of the touch sensor as viewed from above the detection surface.

[0007] According to a third aspect of the present disclosure, there is provided a pen state detection circuit that is connected to a touch sensor of a capacitance type and adapted to detect a state of an electronic pen in accordance with an output signal from the touch sensor, the touch sensor including a plurality of sensor electrodes disposed in a planar manner, the electronic pen including a first electrode and a second electrode, the pen state detection circuit including: a processor; and a memory storing instructions that, when executed by the processor, cause the pen state detection circuit to sequentially and repeatedly: acquire first coordinate values and second coordinate values in a sensor coordinate system, the coordinate system being defined on a detection surface of the touch sensor, the first coordinate values indicating a projected position of the first electrode, the second coordinate values indicating a projected position of the second electrode; calculate an inclination value indicative of an inclination of the electronic pen from the first coordinate values and second coordinate values in accordance with calculation rules, and output the inclination value, wherein time-series inclination values sequentially outputted when the electronic pen is positioned at a periphery of the touch sensor during the movement of the electronic pen are smoothed to a greater extent than time-series inclination values sequentially outputted when the electronic pen is positioned at a central portion of the touch sensor.

[0008] According to a fourth aspect of the present disclosure, there is provided a pen state detection circuit that is connected to a touch sensor of a capacitance type and adapted to detect a state of an electronic pen in accordance with an output signal from the touch sensor, the touch sensor including a plurality of sensor electrodes disposed in a planar manner, the electronic pen including a first electrode and a second electrode, the pen state detection circuit including: a processor; and a memory storing instructions that, when executed by the processor, cause the pen state detection circuit to sequentially and repeatedly: acquire first coordinate values and second coordinate values in a sensor coordinate system, the coordinate system being defined on a detection surface of the touch sensor, the first coordinate values indicating a projected position of the first electrode, the second coordinate values indicating a projected position of the second electrode; calculate an

inclination value indicative of an inclination of the electronic pen from the first coordinate values and second coordinate values in accordance with calculation rules; and output the inclination value, wherein time-series inclination values sequentially outputted when the electronic pen is positioned at a bend of the touch sensor during the movement of the electronic pen are more smoothed than time-series inclination values sequentially outputted when the electronic pen is positioned at a flat portion of the touch sensor. One or more aspects of the present disclosure make it possible to inhibit unexpected results from being obtained from a periphery or a bend of a touch sensor when the inclination of an electronic pen having two electrodes is calculated.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

[0009] FIG. **1** is a diagram illustrating an example of an input system incorporating a pen state detection circuit according to a first embodiment of the present disclosure;

[0019] FIG. **11** is a diagram illustrating an example of an input system for performing a pen pressure value output method according to a second embodiment of the present disclosure;

[0020] FIG. **12** is a block diagram illustrating a pen detection function of the touch IC depicted in FIG. **11**;

[0021] FIG. **13** is a flowchart illustrating execution of the pen detection function depicted in FIG. **12**;

[0022] FIG. **14** is a schematic diagram illustrating a part of the electronic pen depicted in FIG. **11**;

[0023] FIG. **15** is a diagram illustrating an example of a pen pressure correction property used for correcting a pen pressure value;

[0024] FIG. **16** is another flowchart illustrating a case where the electronic pen corrects the pen pressure value;

[0025] FIG. **17** is a diagram illustrating an example of an input system incorporating the pen state detection circuit according to a third embodiment of the present disclosure;

[0026] FIG. **18** is a block diagram illustrating a pen detection function of the touch IC depicted in FIG. **17**;

[0027] FIG. **19** is a flowchart illustrating execution of the pen detection function depicted in FIG. **18**;

[0028] FIG. **20** is a schematic side cross-sectional view illustrating an electronic device depicted in FIG. **17**;

[0029] FIGS. **21**A and **21**B are diagrams illustrating exemplary methods of dividing the sensor

region;

[0030] FIGS. **22**A and **22**B are diagrams illustrating a first exemplary result of a scan region determination;

[0031] FIGS. **23**A and **23**B are diagrams illustrating a second exemplary result of a scan region determination;

[0032] FIGS. **24**A and **24**B are diagrams illustrating a third exemplary result of a scan region determination; and

[0033] FIGS. **25**A and **25**B are diagrams illustrating an example of an alternative scanning operation performed by a scan control circuit.

DETAILED DESCRIPTION

[0034] A pen state detection circuit and a pen state detection method, which are provided by the present disclosure, will now be described with reference to the accompanying drawings. The present disclosure is not limited to embodiments and modifications described below. It is obvious that the embodiments and modifications described below may be freely changed without departing from the spirit and scope of the present disclosure. Alternatively, various configurations may be combined as appropriate without causing technical inconsistencies.

First Embodiment

[0035] A pen state detection circuit and a pen state detection method according to a first embodiment of the present disclosure are described below with reference to FIGS. **1** to **10**B.

<Overall Configuration of Input System **10**>

[0036] FIG. **1** is a diagram illustrating an example of an input system **10** incorporating the pen state detection circuit according to the first embodiment of the present disclosure. The input system **10** includes an electronic device **12** and an electronic pen **14** (referred to also as a "stylus"). The electronic device **12** has a touch panel display. The electronic pen **14** is a pen-shaped pointing device.

[0037] The electronic device **12** is formed, for example, of a tablet terminal, a smartphone, or a personal computer. A user holding the electronic pen **14** with one hand is able to write pictures and characters on the electronic device **12** by pressing a tip of the electronic pen **14** on a detection surface **16** of the electronic device **12** and moving the tip of the electronic pen **14** as desired. Further, the user is able to perform a desired operation through a displayed user control by placing a finger F of the user into contact with the detection surface **16**.

[0038] The electronic device **12** includes a touch sensor **18**, a touch integrated circuit (IC) **20**, and a host processor **22**. The touch IC **20** functions as the pen state detection circuit. The touch sensor **18** is formed by combining a plurality of electrodes disposed on a display panel (not depicted). The touch sensor **18** includes a plurality of sensor electrodes **18**x for detecting a position on an X-axis and a plurality of sensor electrodes **18**y for detecting a position on a Y-axis. The x-direction and the y-direction depicted in FIG. **1** respectively correspond to the X-axis and the Y-axis of an orthogonal coordinate system defined on the detection surface **16** formed by the touch sensor **18**.

[0039] The sensor electrodes **18**x, which are each shaped like a belt and extended in the y-direction, are disposed at equal intervals in the x-direction. The sensor electrodes **18**y, which are each shaped like a belt and extended in the x-direction, are disposed at equal intervals in the y-direction. The intervals at which the sensor electrodes **18**x (or the sensor electrodes **18**y) are disposed may be hereinafter expressed by using the word "pitch." As a substitute for a mutual-capacitive sensor described above, a self-capacitive sensor formed of block-shaped electrodes disposed in a two-dimensional grid pattern may be used as the touch sensor **18**.

[0040] The touch IC **20** is an integrated circuit that includes a microcontroller **24** having a processor **26** and a memory **28**, wherein the processor **24** capable of executing firmware (e.g., instructions) stored in the memory **24**, and is connected to the sensor electrodes **18**x and **18**y included in the touch sensor **18**. The microcontroller **24** is capable of implementing a touch detection function and a pen detection function. The microcontroller **24** performing the touch

detection function detects a touch, for example, by the finger F of the user. The microcontroller **24** performing the pen detection function detects the state of the electronic pen **14**.

[0041] The touch detection function includes, for example, a function for scanning the touch sensor **18**, a function for creating a heat map (two-dimensional distribution of detection levels) on the touch sensor **18**, and a function for classifying regions on the heat map (e.g., classification of fingers F and palms of hands). The pen detection function includes, for example, a function for scanning the touch sensor **18** (global scan or sector scan), a function for receiving and analyzing a downlink signal, a function for estimating a state of the electronic pen **14** (e.g., position, inclination, and pen pressure), and a function for generating and transmitting an uplink signal including a command for the electronic pen **14**.

[0042] The host processor **22** includes a central processing unit (CPU) or a graphics processing unit (GPU). The host processor **22** reads a program from a memory (not depicted) and executes the read program to thereby perform a process of generating digital ink by using data from the touch IC **20** and a rendering process for displaying a drawing indicated by the digital ink, for example.

<Pen State Estimation Method>

[0043] FIG. **2** is a schematic diagram illustrating a part of the electronic pen **14** depicted in FIG. **1**. The electronic pen **14** includes a tip electrode **30** and an upper electrode **32**. The tip electrode **30**, which is conical in shape, is symmetrically shaped with respect to a central axis of the electronic pen **14** and disposed on the tip of the electronic pen **14**. The upper electrode **32**, which is tapered and annular (e.g., frustoconical) in shape, is symmetrically shaped with respect to the axis of the electronic pen **14** and disposed closer to a base end than the tip electrode **30**.

[0044] The tip electrode **30** and the upper electrode **32** output signals (so-called downlink signals) generated by an oscillator circuit **34**. As the oscillator circuit **34** changes an oscillation frequency or changes a destination in a time-division manner, the electronic pen **14** is able to output two different downlink signals through the tip electrode **30** and the upper electrode **32**, respectively.

[0045] The touch IC **20** (FIG. **1**) in the electronic device **12** acquires, from the touch sensor **18**, a signal distribution (hereinafter referred to as a "first signal distribution") indicative of a change in capacitance (more specifically, mutual-capacitance or self-capacitance) that occurs when the tip electrode **30** is in proximity to the touch sensor **18**. The first signal distribution is typically shaped to have one peak at a position Q**1**. The position Q**1** corresponds to a position where an apex (position P**1**) of the tip electrode **30** is projected onto the detection surface **16**.

[0046] Similarly, the touch IC **20** (FIG. **1**) in the electronic device **12** acquires, from the touch sensor **18**, a signal distribution (hereinafter referred to as a "second signal distribution") indicative of a change in capacitance that occurs when the upper electrode **32** is in proximity to the touch sensor **18**. The second signal distribution is typically shaped to have one or two peaks at a position Q**2**. The position Q**2** corresponds to a position where a shoulder (position P**2**) of the upper electrode **32** is projected onto the detection surface **16**. A position P**3**, which will be described later, corresponds to a center of an upper base of the upper electrode **32**.

[0047] FIGS. **3**A and **3**B are diagrams illustrating examples of signal distributions that are obtained when the electronic pen **14** is in a contact state. More specifically, FIG. **3**A illustrates the first signal distribution, and FIG. **3**B illustrates the second signal distribution. In FIGS. **3**A and **3**B, the horizontal axis of each graph represents a relative position (unit: millimeters) with respect to an indicated position indicated by the electronic pen **14**, and the vertical axis of each graph represents a signal value (unit: none) normalized to [**0**,**1**]. For the signal value, positive and negative signs are defined in such a manner that the signal value is "positive" when the electronic pen **14** is in proximity to the touch sensor **18**. The first signal distribution and the second signal distribution both vary in shape depending on the inclination of the electronic pen **14** (hereinafter referred to also as "pen inclination"). In FIGS. **3**A and **3**B, three curves obtained by varying the pen inclination are depicted in an overlapping manner.

[0048] As depicted in FIG. **3**A, the shapes of the first signal distribution are substantially similar to

each other irrespective of the pen inclination. The reason is that, while the electronic pen **14** is used, the apex of the tip electrode **30** is usually closest to the detection surface **16** to make the position Q**1** substantially coincide with the position P**1**. Meanwhile, as depicted in FIG. **3**B, the second signal distribution is such that the position of a peak or the number of peaks significantly varies with changes in the pen inclination. The reason is that, while the electronic pen **14** is used, either one of the shoulders of the upper electrode **32** is usually closest to the detection surface **16** to make the distance between the positions Q**1** and Q**2** vary with the pen inclination.

[0049] The position and the posture of the electronic pen **14** can be estimated by using the coordinates of the positions Q**1** and Q**2**. For example, the indicated position corresponds to the position Q**1** depicted in FIG. **2**. The pen inclination corresponds to an angle (hereinafter referred to as an "inclination angle θ") between a direction that is perpendicular to the detection surface **16** and the axis of the electronic pen **14**. More specifically, θ=0° in a state where the pen inclination is perpendicular to the detection surface **16**, and θ=90° in a state where the pen inclination is parallel to the detection surface **16**. As a physical quantity indicative of the inclination of the electronic pen **14**, an orientation indicative of the "direction" of inclination may be used instead of an angle indicative of the "magnitude" of inclination.

[0050] FIG. **4** is a schematic side cross-sectional view illustrating the electronic device **12** depicted in FIG. **1**. Linearly disposed rectangles schematically represent the sensor electrodes **18**x and **18**y (FIG. **1**), which are arrayed in a planar manner. In the example of FIG. **4**, the electronic device **12**, which is flat, is folded into halves in such a manner that the detection surface **16** faces outwardly while a non-detection surface **40** faces inwardly. This enables the user to perform input operations by using the electronic pen **14** and the finger F even in a state where the electronic device **12** is folded.

[0051] As the tip electrode **30** and upper electrode **32** of the electronic pen **14** are disposed at a physical distance from each other, there may arise a situation where the positions Q**1** and Q**2** are not correctly detected depending on the relative positional relationship between the electronic pen **14** and the touch sensor **18**. The situation may arise, for example, [**1**] when only the position Q**2** is left undetected at a periphery **42**, [**2**] when the accuracy of detection of the positions Q**1** and Q**2** is lowered due to electromagnetic wave interference caused at a periphery **44** by electronic parts **45** including a camera unit, and [**3**] when the position Q**2** is occasionally left undetected at a bend **46**.

[0052] Stated differently, a problem occurs so that unexpected calculation results regarding the state of the electronic pen **14** are outputted when the positions Q**1** and Q**2** are left undetected or when the detected positions Q**1** and Q**2** are deviated from actual projected positions. Therefore, a pen state detection method is proposed to address the above problem. The proposed pen state detection method inhibits unexpected calculation results from being obtained from the peripheries **42** and **44** or the bend **46** of the touch sensor **18** when the inclination of the electronic pen **14** including the tip electrode **30** and the upper electrode **32** is calculated.

<Operation of Touch IC **20**>

[0053] FIG. **5** is a diagram illustrating an exemplary diagram of a sensor region **50** of the touch sensor **18**. An adopted sensor coordinate system is a two-dimensional orthogonal coordinate system that has an origin O, an X-axis, and a Y-axis. The origin O is a feature point (e.g., upper left vertex) on the detection surface **16**. An X-Y plane coincides with the planar direction of the detection surface **16**. The sensor region **50** includes at least one of a peripheral region **52** corresponding to the periphery **42** (FIG. **4**), a peripheral region **54** corresponding to the periphery **44** (FIG. **4**), and a bend region **56** corresponding to the bend **46** (FIG. **4**). The remaining portion of the sensor region **50** is a general region **58** that corresponds to a flat general section **48** depicted in FIG. **4**. The shape of each region (e.g., width, position, and size) can be variously set depending on the electronic device **12** or the electronic pen **14**.

[0054] FIG. **6** is a block diagram illustrating the pen detection function of the touch IC **20** depicted in FIG. **1**. The pen detection function is implemented by a signal acquisition circuit **60**, a peak

estimation circuit **62**, an inclination value calculation circuit **64**, and a coordinate value calculation circuit **66**. The functions of the signal acquisition circuit **60**, peak estimation circuit **62**, inclination value calculation circuit **64**, coordinate value calculation circuit **66** may be performed by the processor **26** while processor **26** executes instructions stored in the memory **28**. An operation performed by the touch IC **20** while the processor **26** executes instructions stored in the memory **28** to perform the pen detection function will now be described with reference to the flowchart of FIG. **7**.

[0055] At S**1** of FIG. **7**, the signal acquisition circuit **60** acquires the first signal distribution and the second signal distribution from the touch sensor **18** through a scanning operation performed on each of the sensor electrodes **18***x* and **18***y*. Each of the signal distributions may be a one-dimensional signal distribution along the X- or Y-axis or a two-dimensional signal distribution on the X-Y axis plane.

[0056] At S**2**, the peak estimation circuit **62** estimates a peak of the first signal distribution acquired at S**1**. More specifically, the peak estimation circuit **62** creates a curve by performing interpolation or approximation of the first signal distribution, which is discrete, and calculates first coordinate values corresponding to a peak of the created curve. Similarly, the peak estimation circuit **62** creates a curve by performing interpolation or approximation of the second signal distribution, which is discrete, and calculates second coordinate values corresponding to a peak of the created curve. The "first coordinate values" indicate a projected position of the tip electrode **30** (hereinafter referred to as a "first position"), and the "second coordinate values" indicate a projected position of the upper electrode **32** (hereinafter referred to as a "second position").

[0057] At S**3**, the inclination value calculation circuit **64** acquires decision parameters necessary for later-described decision. The decision parameters may be, for example, parameters for identifying the position and the shape of the peripheral regions **52** and **54** or the bend region **56** (FIG. **5**) or parameters for identifying the state of the electronic pen **14**.

[0058] At S**4**, the inclination value calculation circuit **64** uses the first or second coordinate values acquired at S**2** and the decision parameters acquired at S**3** to determine whether or not predetermined decision conditions are satisfied. The "decision conditions" represent a situation where at least one of the tip electrode **30** and the upper electrode **32** is potentially in a position interfering with the peripheries **42** and **44** or the bend **46** as viewed from above the detection surface **16**.

[0059] FIG. **8** is a diagram illustrating exemplary combinations of decision conditions and calculation methods. "First conditions A" represent a situation where (1) the first position is at the general section **48** and (2) the second position is at the periphery **42**. In other words, it is determined that the first conditions A are satisfied when (1) the first coordinate values indicate a position in the general region **58** and (2) the second coordinate values indicate a position in the peripheral region **52**.

[0060] "First conditions B" represent a situation where (1) the first position has moved outwardly from the inside of the touch sensor **18** and (2) the second position is at the periphery **42**. In other words, it is decided that the first conditions B are satisfied when (1) the first coordinate values indicate an outward movement from the inside of the sensor region **50** and (2) the second coordinate values indicate a position in the peripheral region **52**.

[0061] "Second conditions" represent a situation where (1) the first position is detected and (2) the second position is not detected. In other words, it is decided that the second conditions are satisfied when (1) the first coordinate values can be acquired and (2) the second coordinate values cannot be acquired.

[0062] A "third condition" represents a situation where the first position or the second position is at a specific periphery **44**. In other words, it is decided that the third condition is satisfied when at least one of a pair of the first coordinate values and a pair of the second coordinate values indicates a position in the peripheral region **54**.

[0063] "Fourth conditions A" represent a situation where (1) the first or second position is at the bend **46** and (2) the bend **46** forms a protruded detection surface **16**. In other words, it is decided that the fourth conditions A are satisfied when (1) at least one of a pair of the first coordinate values and a pair of the second coordinate values indicates a position in the bend region **56** and (2) a flag value regarding the bend direction of the bend region **56** indicates an "upward protrusion."

[0064] "Fourth conditions B" represent a situation where (1) the first or second position is at the bend **46** and (2) the bend **46** forms a recessed detection surface **16**. In other words, it is decided that the fourth conditions B are satisfied when (1) at least one of a pair of the first coordinate values and a pair of the second coordinate values indicates a position in the bend region **56** and (2) the flag value regarding the bend direction of the bend region **56** indicates a "downward protrusion."

[0065] For decision purposes, the inclination value calculation circuit **64** may define and use additional conditions representing "a situation where the electronic pen **14** is in a contact state" in addition to the plurality of sets of above-mentioned decision conditions. The "contact state" is a state where the tip electrode **30** of the electronic pen **14** is in contact with the detection surface **16** of the electronic device **12**. Conversely, a "hover state" is a state where the tip electrode **30** of the electronic pen **14** is not in contact with the detection surface **16** of the electronic device **12**. In a case where, for example, the electronic pen **14** includes a pen pressure sensor **38** (FIG. **14**), the touch IC **20** is able to identify the above-mentioned two states by analyzing a downlink signal transmitted from the electronic pen **14**.

[0066] If none of the plurality of sets of predetermined decision conditions is satisfied ("NO" at S**4**), processing proceeds to S**5**. Meanwhile, if one of the plurality of sets of predetermined decision conditions is satisfied ("YES" at S**4**), processing proceeds to S**6**.

[0067] At S**5**, the inclination value calculation circuit **64** calculates an inclination value (hereinafter referred to as "ordinary calculated value") indicative of current pen inclination in accordance with ordinary calculation rules, which use the first and second coordinate values currently acquired at S**2**. The "ordinary calculation rules" are rules for calculating the inclination value based on a geometric model that is established on an assumption that the detection surface **16** is flat. More specifically, in a case where the distance between the positions P**1** and P**3** is H and the distance between the positions Q**1** and Q**2** is D, the inclination value calculation circuit **64** calculates an inclination angle θ in accordance with Equation (1) below, where D**0** is the distance between the positions Q**1** and Q**2** when θ=0 [degree].

[00001] $$\theta = \sin^{-1}(D/H) - \sin^{-1}(D0/H) \quad (1)$$

[0068] Meanwhile, at S**6**, the inclination value calculation circuit **64** calculates the inclination value in accordance with calculation rules (hereinafter referred to as "special calculation rules") different from the ordinary calculation rules used at S**5**. In other words, the inclination value calculation circuit **64** calculates a value different from the "ordinary calculated value," which is calculated from the currently acquired first and second coordinate values in accordance with the ordinary calculation rules.

[0069] If the first conditions A, the first conditions B, the third condition, or the fourth conditions B in FIG. **8** are satisfied, the inclination value calculation circuit **64** obtains the ordinary calculated value in a similar manner as at S**5**, and then corrects the obtained ordinary calculated value. More specifically, the inclination value calculation circuit **64** outputs a weighted sum of a currently calculated inclination value and one or more previously calculated inclination values (e.g., calculated at the nth last time point; n is a natural number).

[0070] If, for example, the inclination angle indicated by the last outputted inclination value (hereinafter referred to as a "last inclination value") is θprv, and the indication angle indicated by the ordinary calculated value is θcal, the inclination value calculation circuit **64** calculates the inclination angle θ in accordance with Equation (2) below.

[00002] $$\theta = (1 - \alpha) \times \theta cal + \alpha \times \theta prv \quad (2)$$

[0071] A coefficient α in the above equation is a positive value satisfying 0<α<1, and corresponds to a parameter representing the level of smoothing. In other words, the greater the value of the coefficient α is, the higher the level of smoothing is, whereas the smaller the value of the coefficient α is, the lower the level of smoothing is.

[0072] If the second conditions are satisfied, the inclination value calculation circuit **64** outputs an inclination value that is obtained earlier than the current inclination value. More specifically, if θprv is the latest valid value, the inclination value calculation circuit **64** calculates the inclination angle θ in such a manner that θ=θprv. This equation coincides with Equation (2) if α=1.

[0073] If the fourth conditions B are satisfied, the inclination value calculation circuit **64** outputs an inclination value indicating that the electronic pen **14** is perpendicular to the detection surface **16**. More specifically, the inclination value calculation circuit **64** calculates the inclination angle θ in such a manner that θ=0. When the position of the bend **46** is identifiable in a case where the touch sensor **18** can be bent or curved at two or more points, the inclination value calculation circuit **64** may decide whether fourth conditions A or B are satisfied only with regard to the bend region **56** including the position of the bend **46**.

[0074] At S**7**, the coordinate value calculation circuit **66** corrects the indicated position indicated by the electronic pen **14** (i.e., first coordinate values) by using the inclination value calculated at S**5** or S**6**. This reduces the displacement of the indicated position that is based on the inclination angle θ. The pen detection function may use this inclination value to correct a state value (e.g., pen pressure value) other than the indicated position.

[0075] At S**8**, the microcontroller **24** performing the pen detection function supplies data including state values (more specifically, coordinate values, inclination value, pen pressure value, etc.) indicative of the state of the electronic pen **14** to the host processor **22**. In this manner, the flowchart of FIG. **7** ends. The touch IC **20** is able to detect temporal changes in the state of the electronic pen **14** by performing the process shown in this flowchart successively at predetermined time intervals. Exemplary results of calculation of the inclination angle θ are described below with reference to FIGS. **9**A and **9**B and FIGS. **10**A and **10**B.

[0076] FIG. **9**A is a diagram illustrating a first behavior of the electronic pen **14**. Let us assume a case where, for example, the user swings the electronic pen **14** in the left-right direction around a fixation point on the detection surface **16** at which the tip of the electronic pen **14** is fixed. The width and the cycle of the swing are assumed to be constant irrespective of the position of the fixation point.

[0077] FIG. **9**B is a diagram illustrating temporal changes in the inclination angle θ that is successively calculated based on the first behavior. The horizontal axis of a graph in FIG. **9**B represents time (unit: seconds), whereas the vertical axis of the graph represents the inclination angle θ (unit: degrees). A solid-line curve G**1** corresponds to the inclination angle θ calculated when the fixation point is at the general section **48**, that is, the inclination angle θ calculated in accordance with the ordinary calculation rules. Meanwhile, a broken-line curve G**2** corresponds to the inclination angle θ calculated when the fixation point is at the periphery **42**, that is, the inclination angle θ calculated in accordance with the special calculation rules ("first conditions A" in FIG. **8**). A curve G**3** corresponds to an actual value of the inclination angle θ.

[0078] As is understandable from FIG. **9**B, the behaviors indicated by the curves G**1** to G**3** vary in substantially the same cycle around θ=0 [degree]. The curve G**1** has substantially the same shape as the curve G**3**. However, the curve G**2** is shaped in such a manner as to indicate a narrower range of the inclination angle θ than the curve G**1**. In other words, the time-series of the inclination angle θ is smoothed by using the special calculation rules.

[0079] FIG. **10**A is a diagram illustrating a second behavior of the electronic pen **14**. Let us assume a case where, for example, the user moves the electronic pen **14** in such a manner as to pass the bend **46** having an L-shaped curve. The detection surface **16** of the electronic device **12** is assumed to have a downwardly protrusion, L-shaped curve at the bend **46**.

[0080] FIG. **10**B is a diagram illustrating temporal changes in the inclination angle θ that is successively calculated based on the second behavior. The horizontal axis of a graph in FIG. **10**B represents time (unit: seconds), whereas the vertical axis of the graph represents the inclination angle θ (unit: degrees). A solid-line curve G**1** indicates a comparative example, a broken-line curve G**2** indicates an exemplary embodiment, and a thick solid-line curve G**3** indicates an actual value. The "comparative example" corresponds to a case where only the ordinary calculation rules are applied. The "exemplary embodiment" corresponds to a case where the ordinary calculation rules and the special calculation rules ("fourth conditions B" in FIG. **8**) are applied.

[0081] As indicated by the curve G**3**, the user tends to perform a writing operation with the electronic pen **14** brought into perpendicular contact with the detection surface **16** in order to prevent the tip of the electronic pen **14** from slipping at the bend **46** having a curved recessed surface. In such an instance, the position Q**2** is occasionally left undetected at the bend **46** as indicated by the curve G**1** (comparative example) so that a quasi-state where the electronic pen **14** is suddenly inclined may be detected. In view of such circumstances, the calculation rules suitable for the bend **46** are applied as indicated by the curve G**2** (exemplary embodiment). This partially smooths the time-series of the inclination angle θ. Consequently, obtained calculation results indicate a behavior close to the actual behavior of the electronic pen **14**.

Summary of First Embodiment

[0082] As described above, the touch IC **20** is a pen state detection circuit that is connected to the touch sensor **18** of a capacitance type and adapted to detect the state of the electronic pen **14** in accordance with an output signal from the touch sensor **18**. The touch sensor is configured such that the plurality of sensor electrodes **18***x* and **18***y* are disposed in a planar manner. The electronic pen **14** includes the tip electrode **30** (first electrode) and the upper electrode **32** (second electrode). The touch IC **20** sequentially and repeatedly performs an acquisition act (S**2**) and an inclination output act (including S**5**, S**6**, and S**8**). The acquisition act acquires the first coordinate values indicating the projected position of the tip electrode **30** and the second coordinate values indicating the projected position of the upper electrode **32**, which are in a sensor coordinate system defined on the detection surface **16** of the touch sensor **18**. The inclination output act calculates the inclination value indicative of the inclination of the electronic pen **14** from the acquired first coordinate values and second coordinate values in accordance with calculation rules, and outputs the calculated inclination value.

[0083] In the inclination output act (S**6** and S**8**), the touch IC **20** then outputs an inclination value when decision conditions are satisfied. The outputted inclination value is different from an inclination value that is calculated in accordance with ordinary calculation rules when the decision conditions are not satisfied. The decision conditions represent a situation where at least one of the tip electrode **30** and the upper electrode **32** is potentially in a position interfering with the peripheries **42** and **44** or the bend **46** of the touch sensor **18** as viewed from above the detection surface **16**. This inhibits unexpected calculation results from being obtained from the peripheries **42** and **44** or the bend **46** of the touch sensor **18** when the inclination of the electronic pen **14** having two electrodes is calculated.

[0084] Further, the touch IC **20** may operate in such a manner that time-series inclination values sequentially outputted from the peripheries **42** and **44** of the touch sensor **18** during the movement of the electronic pen **14** are more smoothed than time-series inclination values sequentially outputted from the general section **48** (central portion) of the touch sensor **18**. Alternatively, the touch IC **20** may operate in such a manner that time-series inclination values sequentially outputted from the bend **46** of the touch sensor **18** during the movement of the electronic pen **14** are more smoothed than time-series inclination values sequentially outputted from the general section **48** (flat portion) of the touch sensor **18**.

Second Embodiment

[0085] A pen pressure value output method according to a second embodiment of the present

disclosure will now be described with reference to FIGS. **11** to **16**. Elements or functions identical with those described in conjunction with the first embodiment are designated by the same reference numerals as the counterparts and may not be redundantly described.

<Overall Configuration of Input System **80**>

[0086] FIG. **11** is a diagram illustrating an example of an input system **80** for performing the pen pressure value output method according to the second embodiment of the present disclosure. The input system **80** includes the electronic pen **14** and an electronic device **82**. As is the case with the first embodiment, the electronic device **82** includes the touch sensor **18**, the touch IC **20**, and the host processor **22**. However, the firmware of the touch IC **20** is capable of implementing a pen detection function that is different from the pen detection function in the first embodiment.

<Operation of Touch IC **20**>

[0087] FIG. **12** is a block diagram illustrating the pen detection function of the touch IC **20** depicted in FIG. **11**. The pen detection function is implemented by an inclination value calculation circuit **86** and a pen pressure correction circuit **88** in addition to the signal acquisition circuit **60** and the peak estimation circuit **62**. The functions of the inclination value calculation section circuit **86** and the pen pressure correction section circuit **88** may be performed by the processor **26** while processor **26** executes instructions stored in the memory **28**. An operation performed by the touch IC **20** while the processor **26** executes instructions stored in the memory **28** to perform the pen detection function will now be described with reference to the flowchart of FIG. **13**.

[0088] At S**11** of FIG. **13**, the signal acquisition circuit **60** acquires the first signal distribution and the second signal distribution from the touch sensor **18** through a scanning operation performed on each of the sensor electrodes **18**x and **18**y. This acquisition is performed in a similar manner as indicated at S**1** of FIG. **7** and will not be described in detail.

[0089] At S**12**, the signal acquisition circuit **60** analyzes a downlink signal from the electronic pen **14**, and acquires a pen pressure value indicating the pen pressure applied to the electronic pen **14**. The pen pressure value correlates with the pen pressure axially applied to the electronic pen **14**. For example, the pen pressure value is defined so that it increases with an increase in the pen pressure.

[0090] FIG. **14** is a schematic diagram illustrating a part of the electronic pen **14** depicted in FIG. **11**. The electronic pen **14** includes a core body **36** and a pen pressure sensor **38** in addition to the tip electrode **30**, the upper electrode **32**, and the oscillator circuit **34**. The core body **36** is connected at one end to the tip electrode **30** and at the other end to the pen pressure sensor **38**. The pen pressure sensor **38** is a pressure sensor capable of measuring the pressure that is axially applied to the electronic pen **14**. Specifically, the pen pressure sensor **38** may achieve detection by a capacitance method, a diffusion resistance method, a resistance line method, a film formation method, a deposition method, or a mechanical method.

[0091] When the electronic pen **14** is perpendicular to the detection surface **16** (θ=0), the pressure applied by the user via the electronic pen **14** is entirely transmitted to the pen pressure sensor **38** as normal force from the detection surface **16**. However, when the electronic pen **14** is inclined from the normal line of the detection surface **16** (θ+0), the pressure applied by the user is multiplied by approximately cos θ so that the resulting decreased pressure is transmitted to the pen pressure sensor **38**. It should be noted that the pen pressure axially applied to the electronic pen **14** varies with the pen inclination as described above.

[0092] At S**13**, the peak estimation circuit **62** acquires the first and second coordinate values by estimating the peak of each of the first and second signal distributions acquired at S**11**. This estimation is performed in a similar manner as indicated at S**2** of FIG. **7** and will not be described in detail.

[0093] At S**14**, the inclination value calculation circuit **86** calculates an inclination value indicative of the pen inclination by using the first and second coordinate values acquired at S**12**. The inclination value calculation circuit **86** may calculate the inclination value in accordance with Equation (1) above or Equation (2) above.

[0094] At S**15**, the pen pressure correction circuit **88** uses the inclination value calculated at S**14** to correct the pen pressure value acquired at S**12**. More specifically, the pen pressure correction circuit **88** corrects the pen pressure value by multiplying a previous pen pressure value by a correction multiplier M.

[0095] FIG. **15** is a diagram illustrating an example of a pen pressure correction property **90** used for correcting the pen pressure value. The horizontal axis of a graph in FIG. **15** represents the inclination angle θ (unit: degrees), whereas the vertical axis of the graph represents the correction multiplier M (unit: none). The pen pressure correction property **90** is a function such that the correction multiplier M monotonically increases with an increase in the absolute value |θ| of the inclination angle θ. When, for example, $M(\theta)=\sec\theta=1/\cos\theta$ is satisfied, $M(0)=1$, $M(45)=\sqrt{2}$, and $M(60)=\sqrt{3}$ is established.

[0096] The pen pressure correction property **90** is not limited to a function shape exemplified in FIG. **15**, but may be a function shape based on the mechanical structure of the electronic pen **14** or the detection performance of the pen pressure sensor **38**. Further, pen pressure value correction may be achieved by the addition of a correction amount AC instead of the above-mentioned multiplication by the correction multiplier M.

[0097] At S**16**, the pen detection function supplies data including state values (e.g., coordinate values, inclination value, and corrected pen pressure value) indicative of the state of the electronic pen **14** to the host processor **22**. In this manner, the flowchart of FIG. **13** ends. The touch IC **20** is able to detect temporal changes in the state of the electronic pen **14** by performing the process of this flowchart successively at predetermined time intervals.

Summary of Second Embodiment

[0098] As described above, the pen pressure value output method uses the input system **80** that includes the electronic pen **14**, which has the pen pressure sensor **38** capable of measuring an axially applied pen pressure, and the electronic device **82**, which has the detection surface **16** for detecting the state of the electronic pen **14**. The electronic device **82** acquires an inclination value indicative of the inclination of the electronic pen **14** from the normal line of the detection surface **16** (S**14**), corrects a pen pressure value indicative of a pen pressure measured by the pen pressure sensor **38** by using the pen pressure correction property **90**, which monotonically increases a correction amount for the inclination value (S**15**), and outputs the corrected pen pressure value (S**16**). This makes it possible to reduce the tendency where the value detected by the pen pressure sensor **38** relatively decreases with an increase in the inclination of the electronic pen **14** from the normal line of the detection surface **16**. Consequently, the resulting pen pressure output matches the user's operation feeling of the electronic pen **14**.

<Alternative Flowchart>

[0099] In the above example, the touch IC **20** in the electronic device **82** calculates the pen pressure value (S**14**), corrects the pen pressure value (S**15**), and outputs the pen pressure value (**16**). However, such acts may alternatively be performed by the electronic pen **14**. When such an alternative scheme is adopted, the input system **80** operates in accordance with the flowchart depicted in FIG. **16**.

[0100] The electronic device **82** acquires the first and second signal distributions (S**21**), then calculates the first and second coordinate values (S**22**), and calculates the inclination value (S**23**). Next, the electronic device **82** transmits an uplink signal including the inclination value calculated at S**23** to the electronic pen **14**. The electronic pen **14** acquires the inclination value included in the uplink signal received from the electronic device **82** (S**24**), then acquires the pen pressure value from the pen pressure sensor **38** (S**25**), and corrects the pen pressure value by using the inclination value (S**26**). Subsequently, the electronic pen **14** outputs the inclination value corrected at S**26** as a downlink signal to the electronic device **82**. Even when the above-described configuration is adopted, it is possible to provide advantages similar to those provided by the second embodiment, that is, obtain a pen pressure output matching the operation feeling.

Third Embodiment

[0101] A pen state detection circuit and a pen state detection method according to a third embodiment of the present disclosure will now be described with reference to FIGS. **17** to **25B**. Elements or functions identical with those described in conjunction with the first embodiment are designated by the same reference numerals as the counterparts and may not be redundantly described.

<Overall Configuration of Input System **100**>

[0102] FIG. **17** is a diagram illustrating an example of an input system **100** incorporating the pen state detection circuit according to the third embodiment of the present disclosure. The input system **100** basically includes the electronic pen **14** and an electronic device **102**. The electronic device **102** is a foldable terminal that includes, for example, the touch sensor **18**, one or more strain sensors **104**, a touch IC **106** functioning as the pen state detection circuit, and a host processor **108**.

[0103] The strain sensors **104** detect changes in the shape of the touch sensor **18** that occur due to the deformation function of the electronic device **102**. In a case where, for example, the electronic device **102** is inflexible, the strain sensors **104** are disposed around a position where the touch sensor **18** bends. Meanwhile, in a case where the electronic device **102** is flexible, the strain sensors **104** are disposed so as to cover the entire surface of the touch sensor **18**.

[0104] The touch IC **106** is an integrated circuit that includes a microcontroller **110** having a processor **112** and a memory **114**, wherein the processor **112** is capable of executing firmware (e.g., instructions) stored in the memory **114**, and is connected to the plurality of sensor electrodes **18**x and **18**y. The microcontroller **110** is capable of implementing a touch detection function and a later-described pen detection function. The touch detection function is the same as or different from the touch detection function described in connection with FIG. **1**.

[0105] The host processor **108** includes a CPU or a GPU, and performs similar processing to the processing by the host processor **22**. The above-mentioned one or more strain sensors **104** are connected to the host processor **108**.

<Operation of Touch IC **106**>

[0106] FIG. **18** is a block diagram illustrating the pen detection function of the touch IC **106** depicted in FIG. **17**. The pen detection function is implemented by a bend information acquisition circuit **120**, a region division circuit **122**, a region determination circuit **124**, a scan control circuit **126**, and an indicated-position detection circuit **128**. The functions of the bend information acquisition circuit **120**, region division circuit **122**, region determination circuit **124**, scan control circuit **126**, and indicated-position detection circuit **128** may be performed by the processor **112** while processor **112** executes instructions stored in the memory **114**. An operation performed by the touch IC **106** while the processor **112** executes instructions stored in the memory **114** to perform the pen detection function **114** will now be described with reference to the flowchart of FIG. **19**.

[0107] At S**31** of FIG. **19**, the bend information acquisition circuit **120** acquires information (hereinafter referred to as "bend information") indicative of a bent shape of the touch sensor **18** on a periodic or non-periodic basis from the host processor **108**. Before this acquisition, the host processor **108** generates the bend information regarding the touch sensor **18** by using sensor signals outputted from the one or more strain sensors **104**.

[0108] FIG. **20** is a schematic side cross-sectional view illustrating the electronic device **102** depicted in FIG. **17**. Linearly disposed rectangles schematically represent the sensor electrodes **18**x and **18**y (FIG. **1**), which are arrayed in a planar manner. In the example of FIG. **20**, the electronic device **102**, which is flat, is folded into a substantially Z-shape in such a manner that a part of the detection surface **16** faces outward.

[0109] In the example of FIG. **20**, the above-mentioned bend information includes information for identifying two bends **136** and **138**. More specifically, the bend information includes "2," which indicates the number of bends **136** and **138**, "coordinate values of folding lines L**1** and L**2**," which indicates the positions of the bends **136** and **138**, "mountain fold/valley fold," which indicates the

orientation of the bends **136** and **138**, and "bending amount," which indicates the bending level of the bends **136** and **138**.

[0110] At S**32**, the bend information acquisition circuit **120** analyzes the bend information acquired at S**31** to thereby determine whether or not the touch sensor **18** is deformed. If the touch sensor **18** is not deformed ("NO" at S**32**), processing returns to S**31**, and sequentially repeats S**31** and S**32** until the touch sensor **18** is determined to be deformed. Meanwhile, if the touch sensor **18** is determined to be deformed ("YES" at S**32**), processing proceeds to the next act, that is, S**33**.

[0111] At S**33**, the region division circuit **122** divides a sensor region **140** of the touch sensor **18** by using the bend information acquired at S**31**. More specifically, the region division circuit **122** sets a plurality of sub-regions **141** to **144** that are partitioned by one or more bending lines identified by the bend information.

[0112] FIGS. **21**A and **21**B are diagrams illustrating exemplary methods of dividing the sensor region **140**. In a case where the touch sensor **18** is folded along two folding lines L**1** and L**2** as depicted in FIG. **21**A, the region division circuit **122** divides the rectangular sensor region **140** into three sub-regions **141**, **142**, and **143** that are partitioned by the two folding lines L**1** and L**2**. Meanwhile, in a case where the touch sensor **18** is folded along one folding line L**1** as depicted in FIG. **21**B, the region division circuit **122** divides the rectangular sensor region **140** into two sub-regions **141** and **144** that are partitioned by one folding line L**1**.

[0113] At S**34**, the region determination circuit **124** determines one or more scan regions **146** from a plurality of sub-regions **141** to **143** divided at S**33**. More specifically, the region determination circuit **124** determines the one or more scan regions **146** that are adjacent to the position of the bend **136** identified by the bend information (i.e., adjacent to the folding lines L**1** and L**2**). Alternatively, the region determination circuit **124** may estimate the three-dimensional shape of the touch sensor **18** from the acquired bend information, and determine a region accessible by the electronic pen **14** (a part or whole of the sensor region **140**) as the scan region **146**.

[0114] At S**35**, the region determination circuit **124** instructs the scan control circuit **126** to change the scan region **146**. The scan control circuit **126** then exercises drive control over the touch sensor **18** in such a manner as to scan for the electronic pen **14** in a newly determined scan region **146**.

[0115] Subsequently, processing returns to S**31** and the process of the flowchart of FIG. **19** is repeatedly performed. In other words, the touch IC **106** detects temporal changes in the state of the electronic pen **14** while dynamically changing the scan region **146** each time the deformation of the touch sensor **18** is detected. Results of determination of the scan region **146**, which are dependent on various deformations of the electronic device **102**, will now be described with reference to FIGS. **22**A to **24**B.

[0116] FIGS. **22**A and **22**B are diagrams illustrating a first exemplary result of determination of the scan region **146**. As depicted in FIG. **22**A, when mountain-folded along the folding line L**1** and valley-folded along the folding line L**2**, the electronic device **102** is deformed into a substantially Z-shape as viewed laterally. Stated differently, in a first deformation state, only a part (exposed portion **131**) of the detection surface **16** is exposed. In this case, as depicted in FIG. **22**B, one sub-region **141** corresponding to the exposed portion **131** is determined as the scan region **146**.

[0117] FIGS. **23**A and **23**B are diagrams illustrating a second exemplary result of determination of the scan region **146**. As depicted in FIG. **23**A, when valley-folded along the folding line L**1** and mountain-folded along the folding line L**2**, the electronic device **102** is deformed into a substantially S-shape as viewed laterally. Stated differently, in a second deformation state, only a part (exposed portion **133**) of the detection surface **16** is exposed. In this case, as depicted in FIG. **23**B, one sub-region **143** corresponding to the exposed portion **133** is determined as the scan region **146**.

[0118] FIGS. **24**A and **24**B are diagrams illustrating a third exemplary result of determination of the scan region **146**. As depicted in FIG. **24**A, the electronic device **102** is bent into an L-shape when mountain-folded along the folding line L**1**, and bent into an L-shape when mountain-folded

along the folding line L**2**. As a result, the electronic device **102** is deformed into a substantially C-shape as viewed laterally. Stated differently, in a third deformation state, the whole of the detection surface **16** (exposed portions **131**, **132**, and **133**) is exposed. In this case, as depicted in FIG. **24**B, three sub-regions **141** to **143** corresponding to the exposed portions **131** to **133** are determined as the scan region **146**.

Summary of Third Embodiment

[0119] As described above, the touch IC **106** is a pen state detection circuit that is connected to the touch sensor **18** of a capacitance type and adapted to detect the state of the electronic pen **14** in accordance with an output signal from the touch sensor **18**. The touch sensor **18** can be bent or curved at two or more points and configured such that the plurality of sensor electrodes **18**x and **18**y are disposed in a planar manner. The touch IC **106** acquires bend information including the information regarding the bends **136** and **138** of the touch sensor **18** (S**31**), determines the one or more scan regions **146** adjacent to the positions of the bends **136** and **138** identified by the bend information (adjacent to the folding lines L**1** and L**2**), which are in the sensor region **140** of the touch sensor **18** (S**34**), and exercises drive control over the touch sensor **18** in such a manner as to scan for the electronic pen **14** in only the determined scan region **146**.

[0120] The above-described configuration makes it possible to determine the scan region **146** suitable for the bent shape of the touch sensor **18**. As a result, scanning is executed more frequently than when the entire sensor region **140** is constantly scanned. This provides improved response in the detection of the electronic pen **14**.

[0121] Further, information regarding bend directions associated with the positions of the bends **136** and **138** may be included as position information, and the touch IC **106** may use the positions and the bend directions of the bends **136** and **138** identified by the bend information to thereby estimate the exposed portions **131** to **133** of the touch sensor **18** that are accessible by the electronic pen **14**, and determine the sub-regions **141** to **143** corresponding to the exposed portions **131** to **133** as the scan region **146**. This ensures that unexposed regions, which are unlikely to be used due to the current shape of the touch sensor **18**, are excluded from the scan region **146**.

Modifications of Scanning Operation

[0122] [1] The above-described scan control is applicable not only to the electronic pen **14**, but also to various types of dielectrics including the finger F of the user. For example, the touch IC **106** may acquire the bend information including the information regarding the positions of the bends **136** and **138** of the touch sensor **18**, determine the one or more scan regions **146** adjacent to the positions of the bends **136** and **138** identified by the bend information, which are in the sensor region **140** of the touch sensor **18**, and exercise drive control over the touch sensor **18** in such a manner as to scan only the determined scan region **146** to determine whether the detection surface **16** is touched by the user. [0123] [2] Further, the scan control circuit **126** may scan the whole of the determined scan region **146** or temporarily stop the scanning of a part of the determined scan region **146**. As an example of the latter case, the scan control circuit **126** may change the scan control in accordance with the results of detection of the electronic pen **14** by the indicated-position detection circuit **128**.

[0124] FIGS. **25**A and **25**B are diagrams illustrating an example of an alternative scanning operation performed by the scan control circuit **126**. In this example, the electronic device **102** is deformed into a substantially C-shape as viewed laterally, as is the case with FIG. **24**A. Stated differently, the touch sensor **18** is bent in such a manner that a pair of exposed portions **131** and **133** face in opposite directions.

[0125] As depicted in FIG. **25**A, while the electronic pen **14** is detected by neither of the exposed portions **131** and **132**, the scan control circuit **126** continuously scans all the sub-regions **141** to **143** included in the scan region **146**. By contrast, as depicted in FIG. **25**B, while the electronic pen **14** is detected by only one exposed portion **131**, the scan control circuit **126** temporarily stops the scanning of the sub-region **143** corresponding to the other exposed portion **133**.

[0126] As described above, while the electronic pen **14** is detected only in one sub-region **141** among a pair of sub-regions **141** and **143** corresponding to the pair of exposed portions **131** and **133** in a case where the touch sensor **18** is bent or curved in such a manner that the pair of exposed portions **131** and **133** face in opposite directions, the scan control circuit **126** of the touch IC **106** may exercise drive control over the touch sensor **18** in such a manner as to temporarily stop the scanning for the electronic pen **14** in the other sub-region **143**. [0127] [3] Moreover, in order to exercise scan control suitable for the state of the electronic device **102**, the bend information acquisition circuit **120** may not only detect a state where deformation caused by bending is completed, but also detect an intermediate state where the deformation is in progress or detect temporal changes in the shape. For example, the touch IC **106** may disable the detection of a user's touch on the detection surface **16** while the electronic device **102** is being deformed. This inhibits the electronic device **102** from performing an operation not intended by the user even in a case where the finger F touches the detection surface **16** during a user's bending operation. Specifically, the above-mentioned "disabling of detection" is accomplished by (1) stopping detection by temporarily stopping the scanning in the scan region **146**, (2) refraining from supplying relevant position information to the host processor **108** even when a touch is detected in the scan region **146**, or (3) supplying the position information regarding a touch as well as a disable flag indicative of disabled detection to the host processor **108**.
[0128] It is to be noted that the embodiments of the present disclosure are not limited to the foregoing embodiments, and that various changes can be made without departing from the spirit of the present disclosure.

Claims

1. A method for outputting a pen pressure value performed in a system including an electronic device and an electronic pen, wherein the electronic pen includes a pen pressure sensor that measures a pen pressure in an axial direction of the electronic pen and generates the pen pressure value, a first electrode, and a second electrode disposed at a position different from the first electrode, wherein the electronic device includes a capacitive touch sensor including a plurality of sensor electrodes arranged in a planar configuration, and a pen state detection circuit that detects a state of the electronic pen based on output signals from the capacitive touch sensor, the method comprising: acquiring, by the electronic device, a first coordinate value indicating a projected position of the first electrode and a second coordinate value indicating a projected position of the second electrode in a sensor coordinate system defined on a detection surface of the capacitive touch sensor; calculating, by the electronic device, an inclination value indicating an inclination of the electronic pen relative to a direction normal to the detection surface using the first coordinate value and the second coordinate value; correcting, by the electronic pen or the electronic device, the pen pressure value generated by the pen pressure sensor using a pen pressure correction characteristic in which a correction amount monotonically increases with respect to the inclination value; and outputting, by the electronic pen or the electronic device, a corrected pen pressure value.
2. The method according to claim 1, further comprising: calculating, by the electronic device, an alternative value different from the inclination value when predetermined judgment conditions are satisfied, wherein the outputting includes outputting, by the electronic pen or the electronic device, the corrected pen pressure value using the alternative value.
3. The method according to claim 2, wherein the predetermined judgment conditions indicate a situation in which, when viewed from above the detection surface, at least one of the first electrode and the second electrode is in a position that at least partially interferes with a peripheral portion or a bending portion of the capacitive touch sensor.
4. The method according to claim 2, wherein the alternative value is one of: the pen pressure value smoothed using a time series of pen pressure values, the pen pressure value most recently

calculated as a valid value, or a zero value indicating that the electronic pen is not inclined.

5. The method according to claim 1, further comprising: acquiring, by the electronic device, the inclination value via communication with the electronic pen, wherein the outputting includes outputting, by the electronic pen, the corrected pen pressure value using the inclination value acquired by the electronic device via communication with the electronic pen.

6. The method according to claim 1, wherein the pen pressure correction characteristic is described by a secant function that is an inverse of a cosine function of an inclination angle.

7. A pen state detection circuit connected to a capacitive touch sensor including multiple sensor electrodes arranged in a planar configuration, wherein the pen state detection circuit detects a state of an electronic pen based on output signals from the capacitive touch sensor, and wherein the electronic pen includes a first electrode, a second electrode disposed at a position different from the first electrode, and a pen pressure sensor that measures a pen pressure in an axial direction of the electronic pen and generates a pen pressure value, the pen state detection circuit comprising: a processor; and a memory storing instructions that, when executed by the processor, cause the pen state detection circuit to: acquire a first coordinate value indicating a projected position of the first electrode and a second coordinate value indicating a projected position of the second electrode in a sensor coordinate system defined on a detection surface of the capacitive touch sensor; calculate an inclination value indicating an inclination of the electronic pen relative to a direction normal to the detection surface using the first coordinate value and the second coordinate value; correct the pen pressure value generated by the pen pressure sensor using a pen pressure correction characteristic in which a correction amount monotonically increases with respect to the inclination value; and output a corrected pen pressure value.

8. The pen state detection circuit according to claim 7, wherein the instructions, when executed by the processor, cause the pen state detection circuit to: calculate an alternative value different from the inclination value when predetermined judgment conditions are satisfied, wherein the corrected pen pressure value is output using the alternative value.

9. The pen state detection circuit according to claim 8, wherein the predetermined judgment conditions indicate a situation in which, when viewed from above the detection surface, at least one of the first electrode and the second electrode is in a position that at least partially interferes with a peripheral portion or a bending portion of the capacitive touch sensor.

10. The pen state detection circuit according to claim 8, wherein the alternative value is one of: the pen pressure value smoothed using a time series of pen pressure values, the pen pressure value most recently calculated as a valid value, or a zero value indicating that the electronic pen is not inclined.

11. The pen state detection circuit according to claim 7, wherein the instructions, when executed by the processor, cause the pen state detection circuit to: acquire the inclination value via communication with the electronic pen, wherein the corrected pen pressure value is output using the inclination value acquired via communication with the electronic pen.

12. The pen state detection circuit according to claim 7, wherein the pen pressure correction characteristic is described by a secant function that is an inverse of a cosine function of an inclination angle.
