Kind Code	B2
Date of Patent	August 19, 2025
Inventor(s)	Liu; Chi-Lin et al.

Multi-bit flip flop

Abstract

A circuit includes a multi-bit flip flop, an integrated clock gating circuit connected to the multi-bit flip flop, and a control circuit connected to the integrated clock gating circuit and the multi-bit flip flop. The control circuit compares output data of the multi-bit flip flop corresponding to input data with the input data. The control circuit generates an enable signal based on comparing the output data of the multi-bit flip flop corresponding to the input data with the input data of the multi-bit flip flop. The control circuit provides the enable signal to the integrated clock gating circuit, wherein the integrated clock gating circuit provides, based on the enable signal, a clock signal to the multi-bit flip flop causing the multi-bit flip flop to toggle.

Background/Summary

CROSS REFERENCE TO RELATED APPLICATION (1) This application is a continuation of Ser. No. 17/082,368 filed Oct. 28, 2020, and titled "Multi-Bit Flip Flop", which claims the benefit of U.S. Provisional Application No. 62/954,987, filed Dec. 30, 2019, and titled "Multi-Bit Flip Flop," the entire disclosures of which are hereby incorporated herein by reference.

BACKGROUND
(1) A flip-flop is a circuit that has two stable states and thereby is capable of serving as one bit of memory. A flip-flop is usually controlled by one or two control signals and a clock signal. The output often includes the complement as well as the normal output. Flip-flops can be either simple (transparent) or clocked (or non-transparent). Clocked flip-flops are specially designed for synchronous (time-discrete) systems and typically implemented as master-slave devices. Flip-flops can be further divided into types: the RS ("set-reset"), D ("data" or "delay"), T ("toggle"), and JK types are common ones. The D flip-flop is known as a delay flip-flop (as its output Q looks like a delay of input D) or data latch. The behavior of a particular type flip-flop can be described by what is termed the characteristic equation, which derives the "present state" output in terms of the input signal(s) and/or the "previous state" signal of the flip-flops.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

(1) Aspects of the present disclosure are best understood from the following detailed description when read with the accompanying figures. It is noted that, in accordance with the standard practice in the industry, various features are not drawn to scale. In fact, the dimensions of the various features may be arbitrarily increased or reduced for clarity of discussion.

(2) FIG. **1** is a block diagram illustrating an example of a processing system in accordance with some embodiments.

(3) FIG. **2** depicts an example of a D-type flip-flop with a shared clock terminal and one output in accordance with some embodiments.

(4) FIG. **3** depicts an example block diagram of a multi-bit flip-flop circuit in accordance with some embodiments.

(5) FIG. **4**A depicts partial block diagram and partial circuit diagram of a multi-bit flip-flop circuit in accordance with some embodiments.

(6) FIG. **4**B depicts a truth table of an exclusive OR logic circuit of a multi-bit flip-flop circuit in accordance with some embodiments.

(7) FIG. **4**C depicts a truth table of a disjunction circuit of a multi-bit flip-flop circuit in accordance with some embodiments.

(8) FIG. **5** is a block diagram showing an example of a multi-bit flip-flop constructed from two single bit flip-flop cells in accordance with some embodiments.

(9) FIG. **6** is a flow diagram illustrating an example method for operating a multi-bit flip-flop in accordance with some embodiments.

DETAILED DESCRIPTION

(10) The following disclosure provides many different embodiments, or examples, for implementing different features of the provided subject matter. Specific examples of components and arrangements are described below to simplify the present disclosure. These are, of course, merely examples and are not intended to be limiting. For example, the formation of a first feature over or on a second feature in the description that follows may include embodiments in which the first and second features are formed in direct contact, and may also include embodiments in which additional features may be formed between the first and second features, such that the first and second features may not be in direct contact. In addition, the present disclosure may repeat reference numerals and/or letters in the various examples. This repetition is for the purpose of simplicity and clarity and does not in itself dictate a relationship between the various embodiments and/or configurations discussed.

(11) Further, spatially relative terms, such as "beneath," "below," "lower," "above," "upper" and the like, may be used herein for ease of description to de scribe one element or feature's relationship to another element(s) or feature(s) as illustrated in the figures. The spatially relative terms are intended to encompass different orientations of the device in use or operation in addition to the orientation depicted in the figures. The apparatus may be otherwise oriented (rotated 90 degrees or at other orientations) and the spatially relative descriptors used herein may likewise be interpreted accordingly.

(12) Electronic Design Automation (EDA) tools and methods facilitate the design, partition, and placement of microelectronic integrated circuits on a semiconductor substrate. This process typically includes turning a behavioral description of the circuit into a functional description, which is then decomposed into logic functions and mapped into cells using a standard cell library. Once mapped, a synthesis is performed to turn the structural design into a physical layout, a clock tree is built to synchronize the structural elements, and the design is optimized post layout.

(13) FIG. **1** is a block diagram illustrating an example of a processing system **100** in accordance with some embodiments disclosed herein. Processing system **100** may be used to perform a method for operating a multi-bit flip-flop in accordance with various processes discussed herein.

Processing system **100** includes a processing unit **110**, such as a desktop computer, a workstation, a laptop computer, a dedicated unit customized for a particular application, a smart phone or tablet, etc. Processing system **100** may be equipped with a display **114** and one or more input/output devices **112**, such as a mouse, a keyboard, touchscreen, printer, etc. Processing unit **110** also includes a central processing unit (CPU) **120**, memory **122**, a mass storage device **124**, a video adapter **126**, and an I/O interface **128** connected to a bus **130**.

(14) Bus **130** may be one or more of any type of several bus architectures including a memory bus or memory controller, a peripheral bus, or video bus. CPU **120** may comprise any type of electronic data processor, and memory **122** may comprise any type of system memory, such as static random access memory (SRAM), dynamic random access memory (DRAM), or read-only memory (ROM).

(15) Mass storage device **124** may comprise any type of storage device configured to store data, programs, and other information and to make the data, programs, and other information accessible via bus **130**. Mass storage device **124** may comprise, for example, one or more of a hard disk drive, a magnetic disk drive, an optical disk drive, flash memory, or the like.

(16) The term computer readable media as used herein may include computer storage media such as the system memory and storage devices mentioned above. Computer storage media may include volatile and nonvolatile, removable and non-removable media implemented in any method or technology for storage of information, such as computer readable instructions, data structures, or program modules. Memory **122** and mass storage device **124** are computer storage media examples (e.g., memory storage). Mass storage device **124** may further store a library of standard cells, as will be discussed further herein below.

(17) Computer storage media may include RAM, ROM, electrically erasable read-only memory (EEPROM), flash memory or other memory technology, CD-ROM, digital versatile disks (DVD) or other optical storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other article of manufacture which can be used to store information and which can be accessed by processing system **100**. Any such computer storage media may be part of processing system **100**. Computer storage media does not include a carrier wave or other propagated or modulated data signal.

(18) Communication media may be embodied by computer readable instructions, data structures, program modules, or other data in a modulated data signal, such as a carrier wave or other transport mechanism, and includes any information delivery media. The term "modulated data signal" may describe a signal that has one or more characteristics set or changed in such a manner as to encode information in the signal. By way of example, and not limitation, communication media may include wired media such as a wired network or direct-wired connection, and wireless media such as acoustic, radio frequency (RF), infrared, and other wireless media.

(19) Video adapter **126** and I/O interface **128** may provide interfaces to couple external input and output devices to processing unit **110**. As illustrated in FIG. **1**, examples of input and output devices include display **114** coupled to video adapter **126** and I/O device **112**, such as a mouse, keyboard, printer, and the like, coupled to I/O interface **128**. Other devices may be coupled to processing unit **110**, and additional or fewer interface cards may be utilized. For example, a serial interface card (not shown) may be used to provide a serial interface for a printer. Processing unit **110** also may include a network interface **140** that may be a wired link to a local area network (LAN) or a wide area network (WAN) **116** and/or a wireless link.

(20) Embodiments of processing system **100** may include other components. For example, processing system **100** may include power supplies, cables, a motherboard, removable storage media, cases, and the like. These other components, although not shown, are considered part of processing system **100**.

(21) In some examples, software code is executed by CPU **120** to operate a multi-bit flip-flop. The software code may be accessed by CPU **120** via bus **130** from memory **122**, mass storage device **124**, or the like, or remotely through network interface **140**. Further, in some examples, a physical

integrated circuit layout may be created based on a functional integrated circuit design, which may be received though I/O interface **128** and/or stored in memory **122** or mass storage device **124** in accordance with various methods and processes implemented by the software code.

(22) A standard cell can include an entire device, such as a transistor, diode, capacitor, resistor, or inductor, or can include a group of several devices arranged to achieve some particular function, such as an inverter, a flip-flop, a memory cell, or an amplifier, among others. In addition to making functional design easier to conceptualize, the use of standard cells can reduce verification time for design rule checking (DRC) of the layout features within the IC, because a standard cell that is repeated throughout the layout can be checked a single time in DRC rather than each instantiation being checked individually. Based on the received functional circuit description, processing system **100** is configured to select standard cells from the cell library.

(23) As noted above, flip-flop circuits may be included in a standard cell library. A flip-flop is a circuit that has two stable states and thereby is capable of serving as one bit of memory. A flip-flop is usually controlled by one or two control signals and a clock signal. The output often includes the complement as well as the normal output. Flip-flops can be either simple (transparent) or clocked (or non-transparent). Clocked flip-flops are specially designed for synchronous (time-discrete) systems and typically implemented as master-slave devices. Flip-flops can be further divided into types: the RS ("set-reset"), D ("data" or "delay"), T ("toggle"), and JK types are common ones. The D flip-flop is known as a delay flip-flop (as its output Q looks like a delay of input D) or data latch. The behavior of a particular type flip-flop can be described by what is termed the characteristic equation, which derives the "present state" output in terms of the input signal(s) and/or the "previous state" signal of the flip-flops.

(24) The D flip-flop captures the value of the D-input at a definite portion of the clock cycle (such as the rising edge of the clock). That captured value becomes the Q output. At other times, the output Q does not change. The D flip-flop can be viewed as a memory cell, a zero-order hold, or a delay line.

(25) FIG. **2** depicts an example D-type flip flop **200** in accordance with aspects of the present disclosure. As shown in FIG. **2**, flip flop **200** includes a data input terminal **202** and a data output terminal **204**. In addition, flip flop **200** of FIG. **2** includes a clock input terminal, CK in, **206**. Flip flop **200** captures a value, that is, input data, D, provided at data input terminal **202** at a definite portion of the clock cycle (such as the rising edge of the clock). That captured input data, D, becomes output data, Q, at data output terminal **204**. At other times, the output data, Q does not change. In some examples, flip flop **200** can be viewed as a memory cell, a zero-order hold, or a delay line.

(26) Multiple single bit flip flops, for example flip flop **200** of FIG. **2**, are arranged to form multi-bit flip flops. Multi-bit flip flops have multiple input terminals and output terminals (D and Q pins). For instance, some two bit multi-bit flip-flops may have two input terminals and two output terminals (D**0**, D**1**, Q**0**, Q**1** pins) along with a common clock, scan_in and scan_enable pins. In a two bit flip flop, the scan_in pin of a second bit flop is connected to a first flop Q pin (Q**0**), so that they are in scanning order. The layout of the multi-bit flip flop may be designed in a compact manner so that the effective area of the multi-bit flip flop is less than the added area of single-bit flip flops.

(27) Known multi-bit flip flops may be employed to save power by sharing a local clock buffer among flip flops, optimizing power by reducing clock-toggling devices. Disclosed embodiments further save power by using a plurality of low clock pulse toggling single-bit flip flops and self-timed integrated clock gating (ICG) cells. In some examples, power is reduced by over 30%.

(28) FIG. **3** illustrates a block diagram of a multi-bit flip flop circuit **300** in accordance with some embodiments. As shown in FIG. **3**, multi-bit flip flop circuit **300** includes multi-bit flip flop **302**, an integrated clock gating circuit **304**, and a control circuit **306**. Multi-bit flip flop **302** is connected to both integrated clock gating circuit **304** and a control circuit **306**. Control circuit **306** includes a

disambiguation circuit **308** and a disjunction circuit **310**. It will be apparent to a person with ordinary skill in the art after reading this disclosure that multi-bit flip flop circuit **300** can include more components than those depicted in FIG. **3**.

(29) As shown in FIG. **3**, multi-bit flip flop **302** includes data input terminals **312**, data output terminals **314**, and clock input terminals **316**. Multi-bit flip flop **302** captures input data, D<provided at data input terminals **312** and provides the captured input data, D, as output data, Q, at output terminals **314**. Multi-bit flip flop **302** receives a clock signal, CLK, at clock input terminals **316** and toggles in response to receiving the clock signal, CLK. In some examples, multi-bit flip flops **302** includes a plurality of single bit flip flops arranged to form multi-bit flip flop **302** operative to temporarily store a pre-determined number of bits of data input. Multi-bit flip flops **302** is connected to control circuit **306**.

(30) Control circuit **306** includes first input terminals **318** and second input terminals **320**. In some examples, disambiguation circuit **308** of control circuit **306** includes first input terminals **318** and second input terminals **320**. First input terminals **318** are connected to input terminals **312** of multi-bit flip flop **302**. Second input terminals **320** are connected to output terminals **314** of multi-bit flip flop **302**. In some example, control circuit **306** compares the input data with the output data of multi-bit flip flop **302** corresponding to the input data, and provides an enable signal, EN, based on the comparison. Control circuit **306** provides the enable signal, EN at control circuit output terminal **326**.

(31) For example, disambiguation circuit **308** of control circuit **306** determines a logical disambiguation of the input data, D, and the output data, Q, of multi-bit flip flop **302** corresponding to the input data, D. Disambiguation circuit **308** provides results of the logical disambiguation determination at disambiguation circuit output terminals **322** of disambiguation circuit **308**. Disambiguation circuit output terminals **322** are connected to disjunction circuit input terminals **324** of disjunction circuit **310**. Hence, the results of the logical disambiguation determination of the input data, D, and the output data, Q, of multi-bit flip flop **302** corresponding to the input data, D, is provided as an input data to disjunction circuit **310**.

(32) Disjunction circuit **310** determines a logical disjunction of the results of logical disambiguation of the input data, D, and the output data, Q, of multi-bit flip flop **302** corresponding to the input data, D. Disjunction circuit **310** generates the enable signal, EN, based on the logical disjunction determination of the results of the logical disambiguation of the input data, D, and the output data, Q, of multi-bit flip flop **302** corresponding to the input data, D. Disjunction circuit **310** provides the enable signal, EN, as an output at disjunction circuit output terminal **326** which is also referred to as control circuit output terminal **326**.

(33) Disjunction circuit output terminal **326** or control circuit output terminal **326** is connected to a second input terminal **330** of integrated clock gating circuit **304**. A first input terminal **328** of integrated clock gating circuit **304** is operative to receive a clock pulse, CP. Integrated clock gating circuit **304** generates the clock signal, CLK, at integrated clock gating circuit output terminal **332**.

(34) In some examples, integrated clock gating circuit **304** generates the clock signal, CLK, from the clock pulse, CP, based on the enable signal, EN. For example, integrated clock gating circuit **304** generates the clock signal, CLK, when the enable signal, EN, changes to a logic high. The clock signal, CLK, is provided at integrated clock gating circuit output terminal **332** which is connected to clock input terminal **316** of multi-bit flip flop **302**. The clock signal, CLK, is provided to multi-bit flip flop **302** and toggles multi-bit flip flop **302**.

(35) FIG. **4**A depicts partial block diagram and partial circuit diagram of a multi-bit flip-flop circuit **400** in accordance with some embodiments. For example, and as shown in FIG. **4**A, multi-bit flip-flop circuit **400** includes a plurality of single bit flop flops, for example, a first single bit flip flop **200(1)**, a second single bit flip flop **200(2)**, a third single bit flip flop **200(3)**, and a fourth single bit flip flop **200(4)**. In some examples, the plurality of single bit flip flops form multi-bit flip flop **302**. Although, multi-bit flip-flop circuit **400** of FIG. **4**A is shown to include only four single bit flip

flops, it will be apparent to a person with an ordinary skill in the art after reading this disclosure that multi-bit flip flop circuit **400** may include a different number of single bit flip flops. For example, multi-bit flip flop circuit **400** may include two single bit flip flops, eight single bit flip flops, sixteen single bit flip flops, and so on.

(36) In addition, multi-bit flip-flop circuit **400** includes a plurality of exclusive OR (XOR) logic circuits, for example, a first XOR logic circuit **402(1)**, a second XOR logic circuit **402(2)**, a third XOR logic circuit **402(3)**, and a fourth XOR logic circuit **402(4)**. In some examples, first XOR logic circuit **402(1)**, second XOR logic circuit **402(2)**, third XOR logic circuit **402(3)**, and fourth XOR logic circuit **402(4)** form disambiguation circuit **308**. Each of the plurality of XOR logic circuits is associated with one of the plurality of single bit flop flops. For example, first XOR logic circuit **402(1)** is associated with first single bit flip flop **200(1)**, second XOR logic circuit **402(2)** is associated with second single bit flip flop **200(2)**, third XOR logic circuit **402(3)** is associated with third single bit flip flop **200(3)**, and fourth XOR logic circuit **402(4)** is associated with fourth single bit flip flop **200(4)**. Thus, and in accordance with some embodiments, multi-bit flip flop circuit **400** includes a same number of or equal number of the plurality of XOR logic circuits and the plurality of single bit flop flops.

(37) First single bit flip flop **200(1)** includes a data input terminal **202(1)**, a data output terminal **204(1)**, and a clock input terminal **206(1)**. In addition, first single bit flip flop **200(1)** includes a scan-in terminal **208(1)**. Data input terminal **202(1)** of first single bit flip flop **200(1)** is operative to receive first input data, D**1**. Clock input terminal **206(1)** of first single bit flip flop **200(1)** is connected to clock gating circuit output terminal **332** and is operative to receive the clock signal, CLK, from integrated clock gating circuit **304**. Scan-in terminal **208(1)** of first single bit flip flop **200(1)** is operative to receive a scan input signal, SI.

(38) First single bit flip flop **200(1)** is operative to capture the first input data, D**1**, received at data input terminal **202(1)** and provide the captured first input data, D**1**, as a first output data, Q**1**, at data output terminal **204(1)**. Data output terminal **204(1)** of first single bit flip flop **200(1)** is connected to a second input terminal **406(1)** of first XOR logic circuit **402(1)**. A first input terminal **404(1)** of first XOR logic circuit **402(1)** is connected to data input terminal **202(1)** of first single bit flip flop **200(1)**. Thus, first input terminal **404(1)** of first XOR logic circuit **402(1)** receives the first input data, D**1**, of first single bit flip flop **200(1)** and second input terminal **406(1)** of first XOR logic circuit **402(1)** receives the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**.

(39) First XOR logic circuit **402(1)** determines a logical disambiguation of the first input data, D**1**, of first single bit flip flop **200(1)** and the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**. First XOR logic circuit **402(1)** provides the first output data, X**1**, which is the logical disambiguation of the first input data, D**1**, of first single bit flip flop **200(1)** and the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**, at output terminal **408(1)**. FIG. **4**B illustrates an example truth table **450** of an example logical disambiguation of the first input data, D**1**, of first single bit flip flop **200(1)** and the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**, in accordance with some embodiments.

(40) As shown in FIG. **4**B, truth table **450** includes columns for the first input data, D**1**, of first single bit flip flop **200(1)**, the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**, and the first output data, X**1**, of first XOR logic circuit **402(1)**. In some examples, the first output data, X**1**, of first XOR logic circuit **402(1)** depends on the first input data, D**1**, of first single bit flip flop **200(1)** and the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**. For example, when the first input data, D**1**, of first single bit flip flop **200(1)** is a logical zero (0) and the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**, is a logical 0, then the first output data, X**1**, of first XOR logic circuit **402(1)** is a logical 0.

(41) By way of another example, when the first input data, D**1**, of first single bit flip flop **200(1)** is a logical 0 and the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**, is a logical one (1), then the first output data, X**1**, is a logical 1. By way of yet another example, when the first input data, D**1**, of first single bit flip flop **200(1)** is a logical 1 and the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**, is a logical 0, then the first output data, X**1**, of first XOR logic circuit **402(1)** is a logical 1. By way of still another example, when the first input data, D**1**, of first single bit flip flop **200(1)** is a logical 1 and the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**, is a logical 1, then the first output data, X**1**, of first XOR logic circuit **402(1)** is a logical 0. Hence, first XOR logic circuit **402(1)** provides the first output data, X**1**, of logical 1 when the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**, is different from the first input data, D**1**. Moreover, first XOR logic circuit **402(1)** provides the first output data, X**1**, of logical 0 when the first output data, Q**1**, of first single bit flip flop **200(1)** corresponding to the first input data, D**1**, is same as the first input data, D**1**.

(42) Returning to FIG. **4**A, second single bit flip flop **200(2)** includes a data input terminal **202(2)**, a data output terminal **204(2)**, and a clock input terminal **206(2)**. In addition, second single bit flip flop **200(2)** includes a scan-in terminal **208(2)**. Data input terminal **202(2)** of second single bit flip flop **200(2)** is operative to receive second input data, D**2**. Clock input terminal **206(2)** of second single bit flip flop **200(2)** is connected to clock gating circuit output terminal **332** and is operative to receive the clock signal, CLK, from integrated clock gating circuit **304**. Scan-in terminal **208(2)** of second single bit flip flop **200(2)** is connected to output terminal **204(1)** of first single bit flip flop **200(1)** and is operative to receive the first output data, Q**1**, of first single bit flip flop **200(1)**.

(43) Second single bit flip flop **200(2)** is operative to capture the second input data, D**2**, received at data input terminal **202(2)** and provide the captured second input data, D**2**, as a second output data, Q**2**, at data output terminal **204(2)**. Data output terminal **204(2)** of second single bit flip flop **200(2)** is connected to a second input terminal **406(2)** of second XOR logic circuit **402(2)**. A first input terminal **404(2)** of second XOR logic circuit **402(2)** is connected to data input terminal **202(2)** of second single bit flip flop **200(2)**. Thus, first input terminal **404(2)** of second XOR logic circuit **402(2)** receives the second input data, D**2**, of second single bit flip flop **200(2)** and second input terminal **406(2)** of second XOR logic circuit **402(2)** receives the second output data, Q**2**, of second single bit flip flop **200(2)** corresponding to the second input data, D**2**.

(44) Second XOR logic circuit **402(2)** determines a logical disambiguation of the second input data, D**2**, of second single bit flip flop **200(2)** and the second output data, Q**2**, of second single bit flip flop **200(2)** corresponding to the second input data, D**2**. Second XOR logic circuit **402(2)** provides the second output data, X**2**, which is the logical disambiguation of the second input data, D**2**, of second single bit flip flop **200(2)** and the second output data, Q**2**, of second single bit flip flop **200(2)** corresponding to the second input data, D**2**, at output terminal **408(2)**. In examples, second XOR logic circuit **402(2)** provides the second output data, X**2**, of logical 1 when the second output data, Q**2**, of second single bit flip flop **200(2)** corresponding to the second input data, D**2**, is different from the second input data, D**2**. Moreover, second XOR logic circuit **402(2)** provides the second output data, X**2**, of logical 0 when the second output data, Q**2**, of second single bit flip flop **200(2)** corresponding to the second input data, D**2**, is same as the second input data, D**2**.

(45) Continuing with FIG. **4**A, third single bit flip flop **200(3)** includes a data input terminal **202(3)**, a data output terminal **204(3)**, and a clock input terminal **206(3)**. In addition, third single bit flip flop **200(3)** includes a scan-in terminal **208(3)**. Data input terminal **202(3)** of third single bit flip flop **200(3)** is operative to receive third input data, D**3**. Clock input terminal **206(3)** of third single bit flip flop **200(3)** is connected to clock gating circuit output terminal **332** and is operative to receive the clock signal from clock gating circuit **304**. Scan-in terminal **208(3)** of third single bit flip flop **200(3)** is connected to output terminal **204(2)** of second single bit flip flop **200(2)** and is operative to receive the second output data, Q**2**, of second single bit flip flop **200(2)**.

(46) Third single bit flip flop **200(3)** is operative to capture the third input data, D**3**, received at data input terminal **202(3)** and provide the captured third input data, D**3**, as a third output data, Q**3**, at data output terminal **204(3)**. Data output terminal **204(3)** of third single bit flip flop **200(3)** is connected to a second input terminal **406(3)** of third XOR logic circuit **402(3)**. A first input terminal **404(3)** of third XOR logic circuit **402(3)** is connected to data input terminal **202(3)** of third single bit flip flop **200(3)**. Thus, first input terminal **404(3)** of third XOR logic circuit **402(3)** receives the third input data, D**3**, of third single bit flip flop **200(3)** and second input terminal **406(3)** of third XOR logic circuit **402(3)** receives the third output data, Q**3**, of third single bit flip flop **200(3)** corresponding to the third input data, D**3**.

(47) Third XOR logic circuit **402(3)** determines a logical disambiguation of the third input data, D**3**, of third single bit flip flop **200(3)** and the third output data, Q**3**, of third single bit flip flop **200(3)** corresponding to the third input data, D**3**. Third XOR logic circuit **402(3)** provides the third output data, X**3**, which is the logical disambiguation of the third input data, D**3**, of third single bit flip flop **200(3)** and the third output data, Q**3**, of third single bit flip flop **200(3)** corresponding to the third input data, D**3**, at output terminal **408(3)**. In examples, third XOR logic circuit **402(3)** provides the third output data, X**3**, of logical 1 when the third output data, Q**3**, of third single bit flip flop **200(3)** corresponding to the third input data, D**3**, is different from the third input data, D**3**. Moreover, third XOR logic circuit **402(3)** provides the third output data, X**3**, of logical 0 when the third output data, Q**3**, of third single bit flip flop **200(3)** corresponding to the third input data, D**3**, is same as the third input data, D**3**.

(48) Still continuing with FIG. **4**A, fourth single bit flip flop **200(4)** includes a data input terminal **202(4)**, a data output terminal **204(4)**, and a clock input terminal **206(4)**. In addition, fourth single bit flip flop **200(4)** includes a scan-in terminal **208(4)**. Data input terminal **202(4)** of fourth single bit flip flop **200(4)** is operative to receive fourth input data, D**4**. Clock input terminal **206(4)** of fourth single bit flip flop **200(4)** is connected to clock gating circuit output terminal **332** and is operative to receive the clock signal from clock gating circuit **304**. Scan-in terminal **208(4)** of fourth single bit flip flop **200(4)** is connected to output terminal **204(3)** of third single bit flip flop **200(3)** and is operative to receive the third output data, Q**3**, of third single bit flip flop **200(3)**.

(49) Fourth single bit flip flop **200(4)** is operative to capture the fourth input data, D**4**, received at data input terminal **202(4)** and provide the captured fourth input data, D**4**, as a fourth output data, Q**4**, at data output terminal **204(4)**. Data output terminal **204(4)** of fourth single bit flip flop **200(4)** is connected to a second input terminal **406(4)** of fourth XOR logic circuit **402(4)**. A first input terminal **404(4)** of fourth XOR logic circuit **402(4)** is connected to data input terminal **202(4)** of fourth single bit flip flop **200(4)**. Thus, first input terminal **404(4)** of fourth XOR logic circuit **402(4)** receives the fourth input data, D**4**, of fourth single bit flip flop **200(4)** and second input terminal **406(4)** of fourth XOR logic circuit **402(4)** receives the fourth output data, Q**4**, of fourth single bit flip flop **200(4)** corresponding to the fourth input data, D**4**.

(50) Fourth XOR logic circuit **402(4)** determines a logical disambiguation of the fourth input data, D**4**, of fourth single bit flip flop **200(4)** and the fourth output data, Q**4**, of fourth single bit flip flop **200(4)** corresponding to the fourth input data, D**4**. Fourth XOR logic circuit **402(4)** provides the fourth output data, X**4**, which is the logical disambiguation of the fourth input data, D**4**, of fourth single bit flip flop **200(4)** and the fourth output data, Q**4**, of fourth single bit flip flop **200(4)** corresponding to the fourth input data, D**4**, at output terminal **408(4)**. In examples, fourth XOR logic circuit **402(4)** provides the fourth output data, X**4**, of logical 1 when the fourth output data, Q**4**, of fourth single bit flip flop **200(4)** corresponding to the fourth input data, D**4**, is different from the fourth input data, D**4**. Moreover, fourth XOR logic circuit **402(4)** provides the fourth output data, X**4**, of logical 0 when the fourth output data, Q**4**, of fourth single bit flip flop **200(4)** corresponding to the fourth input data, D**4**, is same as the fourth input data, D**4**.

(51) Each of the first output data, X**1**, of first XOR logic circuit **402(1)**, the second output data, X**2**, of second XOR logic circuit **402(2)**, the third output data, X**3**, of third XOR logic circuit **402(3)**,

and the fourth output data, X**4**, of fourth XOR logic circuit **402(4)** are provided to disjunction circuit **310** of multi-bit flip flop circuit **400**. For example, output terminal **408(1)** of first XOR logic circuit **402(1)** is connected to one of a plurality of input terminals of disjunction circuit **310**. Moreover, output terminal **408(2)** of second XOR logic circuit **402(2)** is connected to another one of the plurality of input terminals of disjunction circuit **310**. Furthermore, output terminal **408(3)** of third XOR logic circuit **402(3)** is connected to yet another one of the plurality of input terminals of disjunction circuit **310**. In addition, output terminal **408(4)** of fourth XOR logic circuit **402(4)** is connected to yet another one of the plurality of input terminals of disjunction circuit **310**.

(52) Disjunction circuit **310** determines a logical disjunction of the first output data, X**1**, of first XOR logic circuit **402(1)**, the second output data, X**2**, of second XOR logic circuit **402(2)**, the third output data, X**3**, of third XOR logic circuit **402(3)**, and the fourth output data, X**4**, of fourth XOR logic circuit **402(4)** received at the plurality of input terminals of disjunction circuit **310** and generates the enable signal, EN, based on the logical disjunction. In some examples, disjunction circuit **310** is an OR logic circuit. FIG. **4**C illustrates a truth table **460** of the logical disjunction of the first output data, X**1**, of first XOR logic circuit **402(1)**, the second output data, X**2**, of second XOR logic circuit **402(2)**, the third output data, X**3**, of third XOR logic circuit **402(3)**, and the fourth output data, X**4**, of fourth XOR logic circuit **402(4)** received at the plurality of input terminals of disjunction circuit **310**.

(53) As shown in FIG. **4**C, truth table **460** includes columns for the first output data, X**1**, of first XOR logic circuit **402(1)**, the second output data, X**2**, of second XOR logic circuit **402(2)**, the third output data, X**3**, of third XOR logic circuit **402(3)**, the fourth output data, X**4**, of fourth XOR logic circuit **402(4)**, and a logical value of the enable signal, EN. In some examples, the logical value of the enable signal, EN, depends on the first output data, X**1**, of first XOR logic circuit **402(1)**, the second output data, X**2**, of second XOR logic circuit **402(2)**, the third output data, X**3**, of third XOR logic circuit **402(3)**, and the fourth output data, X**4**, of fourth XOR logic circuit **402(4)**. For example, when the first output data, X**1**, of first XOR logic circuit **402(1)** is a logical 0 or 1 (represented as don't care), the second output data, X**2**, of second XOR logic circuit **402(2)** is a logical 0 or 1, the third output data, X**3**, of third XOR logic circuit **402(3)** is a logical 0 or 1, and the fourth output data, X**4**, of fourth XOR logic circuit **402(4)** is a logical 1, then the logical value of the enable signal, EN, is a logical 1.

(54) By way of another example, when the first output data, X**1**, of first XOR logic circuit **402(1)** is a logical 0 or 1, the second output data, X**2**, of second XOR logic circuit **402(2)** is a logical 0 or 1, the third output data, X**3**, of third XOR logic circuit **402(3)** is a logical 1, and the fourth output data, X**4**, of fourth XOR logic circuit **402(4)** is a logical 0 or 1, then the logical value of the enable signal, EN, is a logical 1. By way of yet another example, when the first output data, X**1**, of first XOR logic circuit **402(1)** is a logical 0 or 1, the second output data, X**2**, of second XOR logic circuit **402(2)** is a logical 1, the third output data, X**3**, of third XOR logic circuit **402(3)** is a logical 0 or 1, and the fourth output data, X**4**, of fourth XOR logic circuit **402(4)** is a logical 0 or 1, then the logical value of the enable signal, EN, is a logical 1.

(55) By way of yet another example, when the first output data, X**1**, of first XOR logic circuit **402(1)** is a logical 1, the second output data, X**2**, of second XOR logic circuit **402(2)** is a logical 0 or 1, the third output data, X**3**, of third XOR logic circuit **402(3)** is a logical 0 or 1, and the fourth output data, X**4**, of fourth XOR logic circuit **402(4)** is a logical 0 or 1, then the logical value of the enable signal, EN, is a logical 1. By way of yet another example, when the first output data, X**1**, of first XOR logic circuit **402(1)** is a logical 0, the second output data, X**2**, of second XOR logic circuit **402(2)** is a logical 0, the third output data, X**3**, of third XOR logic circuit **402(3)** is a logical 0, and the fourth output data, X**4**, of fourth XOR logic circuit **402(4)** is a logical 0, then the logical value of the enable signal, EN, is a logical 0.

(56) Hence, the logical value of the enable signal, EN is logical 1 when any of the first output data, X**1**, of first XOR logic circuit **402(1)**, the second output data, X**2**, of second XOR logic circuit

402(2), the third output data, X**3**, of third XOR logic circuit **402(3)**, or the fourth output data, X**4**, of fourth XOR logic circuit **402(4)** is a logical 1. That is, the logical value of the enable signal, EN is logical 1 when the output data, Q**1** for any of first single bit flip flop **200(1)**, second single bit flip flop **200(2)**, third single bit flip flop **200(3)**, and fourth single bit flip flop **200(4)** is different than the respective input data, D.

(57) The enable signal, EN, is provided at disjunction circuit output terminal **326** which is connected to second input terminal **330** of integrated clock gating circuit **304**. Thus, the enable signal, EN, is provided to integrated clock gating circuit **304**. Integrated clock gating circuit **304** generates the clock signal at integrated clock gating circuit output terminal **332**. For example, integrated clock gating circuit **304** provides the clock signal when the logical value of the enable signal, EN, is a logical 1. As discussed previously, the logical value of the enable signal, EN, is a logical 1 when the output data of one of the plurality of single bit flip flops of multi-bit flop circuit **400** is different than the input data of the one of the plurality of single bit flip flops from which the output data was captures.

(58) FIG. **5** is a graph **500** illustrating signals one of the plurality of single bit flip flops of multi-bit flip flop circuit **400** in accordance with some embodiments. For example, a first plot **502** of graph **500** is a representative of the clock pulse, CP of integrated clock gating circuit **304** of multi-bit flip flop **400**. Second plot **504** of graph **500** is a representative of the input data, D, of one of the plurality of single bit flip flops of multi-bit flip flop circuit **400**. Third plot **506** of graph **500** is a representative of the output data, Q, of one of the plurality of single bit flip flops of multi-bit flip flop circuit **400** corresponding to the input data, D. Fourth plot **508** is a representative of the enable signal, EN.

(59) As shown at first marker **510** when both the input data, D, and the output data, Q, are at a same logical value (that is logical 0), then the enable signal, EN, is also at a logical 0. However, as shown at second marker **512**, when the input data, D, rises to logical 1 and the output data, Q, remains at logical 0, then the enable signal, EN, rises to logical 1. Furthermore, and as shown at third marker **514** when both the input data, D, and the output data, Q, are rises to logical 1, the enable signal, EN, is drops to logical zero.

(60) Thus, and in accordance with example embodiments, integrated clock gating circuit generates the clock signal to toggle multi-bit flip flop **302** only when the output data of multi-bit flip flop **302** corresponding to an input data is different than the input data. This minimizes the clock pulse, CP and reduces a clock tree power. In addition, the disclosed processes results in less toggling of multi-bit flip flop **302** resulting in power saving. For example, the disclosed processes results in approximately 30.4% power saving at 10% data activity (that is, toggling) and approximately 64.3% power saving at 0% data activity.

(61) FIG. **6**, is a flow diagram of a method **600** for operating a multi-bit flip-flop in accordance with some embodiments. In some examples, method **600** is performed by processing system **100**. In other embodiments, method **600** is stored as instructions on a non-transitory computer readable medium which when executed by processing unit **110** perform method **600**.

(62) At block **610** of method **600**, input data is provided to a multi-bit flip-flop. For example, the input data is provided at input terminals **312** of multi-bit flip flop **302**. Multi-bit flip flop **302** is operative to capture the input data and provide output data at output terminals **314**. In some examples, the data input may include two bits, four bits, eight bits, etc. In some examples, both, the input data and output data corresponding to the input data of multi-bit flip-flop **302** is provided to disambiguation circuit **308**.

(63) At block **620** of method **600**, a logical disambiguation of the input data and output data corresponding to the input data provided to the multi-bit flip-flop is determined. For example, disambiguation circuit **308** of multi-bit flip flop circuit **300** determines the logical disambiguation of the input data and output data corresponding to the input data provided to multi-bit flip-flop **302**. The logical disambiguation of the input data and output data corresponding to the input data

provided to multi-bit flip-flop **302** is provided to disjunction circuit **310**.

(64) At block **630** of method **600**, a logical disjunction of the logical disambiguation of the input data and the output data corresponding to the input data provided to the multi-bit flip-flop is determined. For example, disjunction circuit **310** of multi-bit flip flop circuit **300** determines the logical disjunction of the logical disambiguation of the input data and output data corresponding to the input data provided to multi-bit flip-flop **302**.

(65) At block **640** of method **600**, a enable signal is provided, based on the logical disjunction, to an integrated clock gating circuit connected to the multi-bit flip-flop. For example, the enable signal, EN, is provided to integrated clock gating circuit **304** connected to multi-bit flip flop **302**. The enable signal, EN, is generated based on the logical disjunction of the logical disambiguation of the input data and output data corresponding to the input data provided to multi-bit flip-flop **302**.

(66) At block **650** of method **600**, a clock signal for the multi-bit flip-flop is generated based on the enable signal. For example, integrated clock gating circuit **304** generates the clock signal based on the enable signal, EN from the clock pulse, CP. In some examples, the clock signal is provided to multi-bit flip flop **302** by integrated clock gating circuit **304**. At block **660** of method **600**, the multi-bit flip flop is toggled in response to the clock signal. For example, multi-bit flip flop **302** is toggled when the clock signal rises to a logic high, that is, logical 1.

(67) In accordance with example embodiments, a circuit comprises: a multi-bit flip flop; an integrated clock gating circuit connected to the multi-bit flip flop; and a control circuit connected to the integrated clock gating circuit and the multi-bit flip flop, wherein the control circuit is operative to: compare output data of the multi-bit flip flop corresponding to input data with the input data, generate an enable signal based on comparing the output data of the multi-bit flip flop corresponding to the input data with the input data of the multi-bit flip flop, and provide the enable signal to the integrated clock gating circuit, wherein the integrated clock gating circuit provides, based on the enable signal, a clock signal to the multi-bit flip flop causing the multi-bit flip flop to toggle.

(68) In example embodiments, a circuit comprises: a plurality of single bit flip flops; an integrated clock gating circuit, wherein an output terminal of the integrated clock gating circuit is connected to a clock input terminal of each of the plurality of single bit flip flops; a plurality of disambiguation logic circuits connected to the plurality of single bit flip flops, wherein each of the plurality of disambiguation logic circuits is operative to determine logical disambiguation of input data and output data corresponding to the input data for a corresponding single bit flip flop of the plurality of single bit flip flops; and a disjunction circuit connected to the plurality of disambiguation logic circuits, wherein disjunction circuit is operative to: determine logical disjunction of a plurality of outputs of the plurality of disambiguation logic circuits, and provide an enable signal based on the logical disjunction.

(69) In accordance with example embodiments, a method comprises: providing input data to a multi-bit flip flop; determining a logical disambiguation of the input data and output data from the multi-bit flip flop corresponding to the input data; determining a logical disjunction of the logical disambiguation of the input data and the output data of the multi-bit flip flop corresponding to the input data; providing, based on the logical disjunction, an enable signal to an integrated clock gating circuit connected to the multi-bit flip flop; and generating, based on the enable signal, a clock signal for the multi-bit flip flop.

(70) The foregoing outlines features of several embodiments so that those skilled in the art may better understand the aspects of the present disclosure. Those skilled in the art should appreciate that they may readily use the present disclosure as a basis for designing or modifying other processes and structures for carrying out the same purposes and/or achieving the same advantages of the embodiments introduced herein. Those skilled in the art should also realize that such equivalent constructions do not depart from the spirit and scope of the present disclosure, and that

they may make various changes, substitutions, and alterations herein without departing from the spirit and scope of the present disclosure.

Claims

1. A circuit comprising: a multi-bit flip flop comprising a plurality of single bit flip flops; an integrated clock gating circuit comprising an edge triggered flip flop having a data input terminal, an enable terminal, and an output terminal, wherein the data input terminal of the flip flop of the integrated clock gating circuit receives a clock pulse, and wherein the output terminal of the flip flop of the integrated clock gating circuit is connected directly to a clock input terminal of each single bit flip flop of the multi-bit flip flop; and a control circuit, wherein the control circuit is operative to: determine a plurality of output data comprising a logical disjunction of input data to a data input terminal of each single bit flip flop and output data at corresponding out terminal of the each single bit flip flop corresponding to the input data; determine a logical disjunction of the plurality of output data; generate an enable signal based on the logical disjunction of the plurality of output data, wherein the control circuit being operative to generate the enable signal based on the logical disjunction of the plurality of output data comprises the control circuit being operative to generate the enable signal having a first logic value when the output data corresponding to the input data of any of the plurality of single bit flip flops is different than the input data, and provide the enable signal to the enable terminal of the flip flop of the integrated clock gating circuit; and wherein the flip flop of the integrated clock gating circuit is operative to: generate a clock signal from the clock pulse received at the data input terminal of the flip flop of the integrated clock gating circuit when the enable signal having the first logical value is received at the enable terminal of the flip flop of the integrated clock gating circuit, and directly provide the clock signal to each single bit flip flop of the multi-bit flip flop causing the multi-bit flip flop to toggle.
2. The circuit of claim 1, wherein the multi-bit flip flop comprises eight single bit flip flops.
3. The circuit of claim 1, wherein the control circuit comprises a plurality of exclusive OR (XOR) logic circuits and an OR logic circuit, wherein the OR logic circuit comprises a plurality of input terminals and an output terminal, wherein a first input terminal of each of the plurality of XOR logic circuits is connected to an input terminal of an associated single bit flip flop of the plurality of single bit flip flops and a second input terminal of each of the plurality of XOR logic circuits is connected to an output terminal of the associated single bit flip flop, wherein an output terminal of each of the plurality of XOR logic circuits is connected to one of the plurality of input terminals of the OR logic circuit, wherein the output terminal of the OR logic circuit is connected to the enable terminal of the flip flop of the integrated clock gating circuit.
4. The circuit of claim 1, wherein each of the plurality of single bit flip flops comprises a D flip flop.
5. The circuit of claim 1, wherein the flip flop of the integrated clock gating circuit being operative to generate the clock signal comprises the flip flop of the integrated clock gating circuit being operative to generate the clock signal from the clock pulse received at the data input terminal when the enable signal having a logic value high is received at the enable terminal of the flip flop of the integrated clock gating circuit.
6. The circuit of claim 1, wherein the control circuit comprises a disambiguation circuit comprising the plurality of XOR logic circuits and a disjunction circuit comprising the OR logic circuit.
7. A circuit comprising: a plurality of single bit flip flops; an integrated clock gating circuit comprising an edge triggered flip flop having a data input terminal, an enable terminal, and an output terminal, wherein the data input terminal of the flip flop of the integrated clock gating circuit receives a clock pulse, and wherein the output terminal of the flip flop of the integrated clock gating circuit is directly connected to a clock input terminal of each single bit flip flop of the plurality of single bit flip flops; a plurality of disambiguation logic circuits, wherein each of the

plurality of disambiguation logic circuits is operative to determine logical disambiguation of input data and output data corresponding to the input data for an associated single bit flip flop of the plurality of single bit flip flops; a disjunction logic circuit comprising a plurality of input terminals and an output terminal, wherein the output terminal of each of the plurality of disambiguation logic circuits is connected to one of the plurality of input terminals of the disjunction logic circuit, wherein the output terminal of the disjunction logic circuit is connected to the enable terminal of the integrated clock gating circuit, and wherein the disjunction logic circuit is operative to: generate an enable signal having a first logic value when the output data corresponding to the input data of any of the plurality of single bit flip flops is different than the input data, and provide the enable signal to the enable terminal of the integrated clock gating circuit; and wherein the integrated clock gating circuit is operative to: generate a clock signal from the clock pulse received at the data input terminal and the enable signal having the first logical value is received at the enable terminal of the integrated clock gating circuit, and provide the clock signal to each single bit flip flop of the multi-bit flip flop.

8. The circuit of claim 7, wherein each of the plurality of disambiguation logic circuits comprises an exclusive OR (XOR) logic circuit.

9. The circuit of claim 7, wherein the disjunction logic circuit comprises an OR logic circuit.

10. The circuit of claim 7, wherein an output terminal of the flip flop of the integrated clock gating circuit is connected to a clock input terminal of each of the plurality of single bit flip flops.

11. The circuit of claim 7, wherein each of the plurality of single bit flip flops comprises a D flip flop.

12. The circuit of claim 7, wherein the flip flop of the integrated clock gating circuit being operative to generate the clock signal comprises the flip flop of the integrated clock gating circuit being operative to generate the clock signal from the clock pulse received at the data input terminal when the enable signal having a logic value high is received at the enable terminal of the flip flop of the integrated clock gating circuit.

13. The circuit of claim 7, wherein the plurality of single bit flip flop comprises eight single bit flip flops.

14. A method comprising: providing input data to each of a plurality of single bit flop flops of a multi-bit flip flop; determining, by each of a plurality of disambiguation logic circuits, a logical disambiguation of the input data and output data corresponding to the input data for each of the plurality of single bit flip flops; determining, by a disjunction logic circuit, a logical disjunction of the logical disambiguation of the input data and the output data corresponding to the input data for each of the plurality of single bit flip flops; generating, by the disjunction logic circuit, an enable signal based on the logical disjunction of the logical disambiguation of the input data and the output data corresponding to the input data for each of the plurality of single bit flip flops, wherein generating the enable signal based on the logical disjunction of the logical disambiguation of the input data and the output data corresponding to the input data for each of the plurality of single bit flip flops comprises generating the enable signal having a first logical value when the output data corresponding to the input data of any of the plurality of single bit flip flops is different than the input data; providing, by the disjunction logic circuit, the enable signal to an enable terminal of an edge triggered flip flop of an integrated clock gating circuit connected to the multi-bit flip flop, wherein the output terminal of the disjunction logic circuit is connected to the enable terminal of the flip flop of the integrated clock gating circuit; and generating, by the flip flop of the integrated clock gating circuit, a clock signal for the multi-bit flip flop from a clock pulse received at a data input terminal of the integrated clock gating circuit based on the enable signal having the first logical value received at the enable terminal.

15. The method of claim 14, further comprising toggling the multi bit flip flop in response to the clock signal.

16. The method of claim 14, further comprising toggling the multi-bit flip flop in response to the

clock signal changing from a first logic value to a second logic value.

17. The method of claim 14, wherein generating, based on the enable signal having the first logical value, the clock signal for the multi-bit flip flop comprises generating the clock signal for the multi-bit flip flop when the enable signal is at a logic high.

18. The method of claim 14, wherein each of the plurality of disambiguation logic circuits comprises an exclusive OR (XOR) logic circuit.

19. The method of claim 14, wherein the disjunction logic circuit comprises an OR logic circuit.

20. The method of claim 14, further comprising providing the clock signal to each of the plurality of single bit flip flops, wherein an output terminal of the flip flop of the integrated clock gating circuit is connected to a clock input terminal of each of the plurality of single bit flip flops.
