# INSPECTION ASSISTANCE SYSTEM, INSPECTION ASSISTANCE METHOD, CONTROL METHOD FOR MEDICAL DEVICE, AND COMPUTER-READABLE RECORDING MEDIUM ON WHICH PROGRAM IS RECORDED

## Abstract

An inspection assistance system includes one or more processors including hardware, and the one or more processors are configured to: acquire a video signal including information of a medical image; perform recognition processing based on the video signal, to enable outputting of inspection assistance information for assisting an inspection; acquire identification information included in the video signal, the identification information being different from the information of the medical image; and determine whether the video signal is a video signal for the recognition processing, based on the identification information.

## Publication Classification

## Background/Summary

CROSS REFERENCE TO RELATED APPLICATION [0001] This application is a continuation application of PCT/JP2022/037163 filed on Oct. 4, 2022, the entire contents of which are incorporated herein by this reference.

BACKGROUND OF THE INVENTION
1. Field of the Invention
[0002] The present disclosure relates to an inspection assistance system, an inspection assistance method, a control method for a medical device, and a computer-readable recording medium on which a program is recorded, which are preferable for a device configured to perform an AI determination.
2. Description of the Related Art
[0003] In recent years, medical systems that use an AI (artificial intelligence) for performing various determinations have been developed also in medical fields. For example, in a colonoscopy, an endoscope AI operation assistance system is sometimes employed to perform a high-quality endoscopy with a reduced burden on a patient. The system is configured to judge a current endoscopy status by using an AI, and present assistance information fitted to the status.
[0004] For enabling a highly-accurate AI determination, an endoscopic image suitable for the AI determination is required to be used. However, even if an endoscopic image suitable for the AI determination is picked up, if an erroneous wiring or the like occurs between a video processor apparatus of an endoscope system and an apparatus configured to output operation assistance information and the like by an AI, based on the endoscopic image (hereinafter, referred to as an inspection assistance apparatus), the AI determination is not performed based on the suitable endoscopic image.
[0005] As a technology for preventing such an erroneous wiring, Japanese Patent Application Laid-Open Publication No. 2010-268063 discloses a technology for authenticating a device as a connection party in order to manage whether to permit information communication between electronic devices. In the technology, when an image forming apparatus detects a connection of an external apparatus, the image forming apparatus acquires an external apparatus ID of the external apparatus, and permits the use of the external apparatus if the acquired external apparatus ID matches an external apparatus ID stored in advance.
[0006] This technology is applied to a video processor apparatus and an inspection assistance apparatus, to enable confirmation whether a connection destination device of the communication connection is correct.
[0007] Note that, between the video processor apparatus and the inspection assistance apparatus, two types of connections are used. The two types of connections include a communication connection for transmitting identification signals and control signals, and a video connection for transmitting video signals of endoscopic images. In addition, there is a case where the video processor apparatus is configured to be capable of outputting a video output from a plurality of

types of output ports for respective image transmission formats.

SUMMARY OF THE INVENTION

[0008] An inspection assistance system according to one aspect of the present disclosure includes one or more processors including hardware. The one or more processors are configured to: acquire a video signal including information of a medical image; perform recognition processing based on the video signal, to enable outputting of inspection assistance information for assisting an inspection; acquire identification information included in the video signal, the identification information being different from the information of the medical image; and determine whether the video signal is a video signal for the recognition processing, based on the identification information.

[0009] An inspection assistance method according to one aspect of the present disclosure includes: acquiring a video signal including information of a medical image; acquiring identification information included in the video signal, the identification information being different from the information of the medical image; determining whether the video signal is a video signal for recognition processing based on the identification information; and performing the recognition processing based on the video signal, to output inspection assistance information for assisting an inspection using the medical image.

[0010] A control method for a medical device according to one aspect of the present disclosure includes: acquiring transmission source device information related to a transmission source device which is a transmission source of a medical image: determining whether the transmission source device as a connection destination is suitable, based on the transmission source device information; acquiring a video signal including information of the medical image; performing recognition processing based on the video signal, to enable outputting of inspection assistance information for assisting an inspection; and determining, based on the video signal, whether the video signal is a video signal for the recognition processing.

[0011] A computer-readable recording medium on which a program is recorded according to one aspect of the present disclosure records the program causing a computer to execute procedures for: acquiring transmission source device information related to a transmission source device which is a transmission source of a medical image; determining whether the transmission source device as a connection destination is suitable, based on the transmission source device information; acquiring a video signal including information of the medical image; performing recognition processing based on the video signal, to enable outputting of inspection assistance information for assisting an inspection; and determining, based on the video signal, whether the video signal is a video signal for the recognition processing.

## Description

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] FIG. **1** is a configuration diagram showing an inspection assistance system according to a first embodiment of the present disclosure.

[0013] FIG. **2** is an explanatory diagram for describing one example of a determination method for an input eligibility determination by an AI information confirmation section **13***b*.

[0014] FIG. **3** is an explanatory diagram for describing another example of the determination method for the input eligibility determination by the AI information confirmation section **13***b*.

[0015] FIG. **4** is a flowchart showing an AI determination control by the AI information confirmation section **13***b*.

[0016] FIG. **5** is a flowchart showing a device correctness determination by a connection destination confirmation section **13***a*.

[0017] FIG. **6** is a flowchart showing the device correctness determination by the connection

destination confirmation section **13***a*.

[0018] FIG. **7** is a block diagram showing a modified example.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT(S)

[0019] Hereinafter an embodiment of the present disclosure will be described in detail with reference to drawings.

First Embodiment

[0020] FIG. **1** is a configuration diagram showing an inspection assistance system according to a first embodiment of the present disclosure. The present embodiment enables checking that a medical image suitable for an AI determination is inputted into an inspection assistance apparatus.

[0021] In the present embodiment, the inspection assistance system is applied to an endoscopy, but not limited to the endoscopy. The inspection assistance system is applicable to various kinds of AI processing that adopt AI determinations. For example, the inspection assistance system can be applied to AI processing for outputting endoscope operation guide information based on endoscopic images, AI processing for outputting control information of an automatic insertion endoscope based on endoscopic images, and AI processing for outputting identification information of a lesion and a site of an organ based on endoscopic images.

[0022] FIG. **1** shows configurations of an inspection assistance apparatus **10** and a video processor apparatus **20** that constitute the inspection assistance system according to the first embodiment of the present disclosure. The video processor apparatus **20** is configured to output information to be used for an AI determination to the inspection assistance apparatus **10**.

[0023] The video processor apparatus **20** includes a device information output section **21** and an input information output section **22**. To the video processor apparatus **20**, for example, an endoscope, not shown, which is configured to be inserted into a subject and pick up endoscopic images inside a body cavity, may be connected, and the endoscopic images such as endoscopic inspection images may be supplied from the endoscope to the video processor apparatus **20**. The video processor apparatus **20** is capable of acquiring not only the endoscopic images but also various kinds of information. For example, the video processor apparatus **20** may be configured to be capable of acquiring information on whether the endoscope has been connected to the video processor apparatus **20** and information on whether an inspection by the endoscope has been started. Furthermore, the video processor apparatus **20** may be configured to acquire information related to switching of observation modes of the endoscope, for example, various observation modes such as an NBI (Narrow Band Imaging) mode, an RDI (Red Dichromatic Imaging) mode.

[0024] The device information output section **21** is configured to transmit transmission source device information via a first communication cable C**1** configuring a first communication route. The transmission source device information is information related to a device which is a transmission source (transmission source device) of input information to be inputted into the inspection assistance apparatus **10**, that is, information related to the video processor apparatus **20** which is a connection destination of the inspection assistance apparatus **10**. Note that the transmission source device information transmitted by the device information output section **21** may include, for example, not only ID information for identifying the video processor apparatus **20** but also information related to an action of the video processor apparatus **20** (action information), information related to an operation of the video processor apparatus **20** (operation information), information related to a video format of a video signal outputted from the video processor apparatus **20**, etc. The action information and the operation information in the transmission source device information include the information on whether the endoscope has been connected to the video processor apparatus **20**, the information on whether the inspection by the endoscope has been started, the information related to the switching of the observation modes of the endoscope, etc.

[0025] The input information output section **22** outputs the input information to be inputted to the inspection assistance apparatus **10** via a second communication cable C**2** configuring a second communication route. In other words, the input information output section **22** outputs a video

signal of an image for an AI determination, for example, an image including an endoscopic image such as an endoscopic inspection image, as the input information to be inputted into the inspection assistance apparatus **10**. Note that the image based on the video signal outputted by the input information output section **22** includes, in a part of regions in the image, an endoscopic image as a medical image.

[0026] Note that description has been made that the first communication route and the second communication route are configured respectively with the first communication cable C**1** and the second communication cable C**2**, but not limited thereto. The first and second communication routes may be configured with wireless routes.

[0027] The inspection assistance apparatus **10** includes a device information acquisition section **11**, an input information acquisition section **12**, an input information confirmation section **13**, and an AI determination section **14**. The entirety of the inspection assistance apparatus **10** or at least one of the device information acquisition section **11**, the input information acquisition section **12**, the input information confirmation section **13**, and the AI determination section **14** may be configured by one or more processors using a CPU (Central Processing Unit), an FPGA (Field Programmable Gate Array) or the like, and may operate according to a program stored in a memory, not shown, to control respective sections, or may realize a part of or all of the functions of the respective sections by an electronic circuit of hardware.

[0028] The device information acquisition section **11** acquires the transmission source device information transmitted from the device information output section **21** via the first communication route, and outputs the acquired transmission source device information to the input information confirmation section **13**. The input information acquisition section **12** acquires the input information transmitted from the input information output section **22** via the second communication route, and outputs the acquired input information to the input information confirmation section **13**.

[0029] The input information confirmation section **13** includes a connection destination confirmation section **13***a* and an AI information confirmation section **13***b*. The connection destination confirmation section **13***a* receives the transmission source device information from the device information output section **21**. The connection destination confirmation section **13***a* uses the transmission source device information, to perform a device correctness determination and confirm the correctness of the device. The device correctness determination is a determination on whether the device which is the connection destination, that is, the device of the transmission source of the endoscopic image which is the input information for determining the contents of assistance in the inspection assistance apparatus **10** is a correct device.

[0030] The AI information confirmation section **13***b* receives the input information from the input information output section **22**. The AI information confirmation section **13***b* performs an input eligibility determination on whether the input information is suitable, for example, for predetermined recognition processing such as the AI determination to output an input eligibility determination result, which is a determination result, to the AI determination section **14**.

[0031] The AI determination section **14** receives the input information, and the input eligibility determination result from the AI information confirmation section **13***b*. The AI determination section **14** decides whether to use the input information for the AI determination, based on the input eligibility determination result. Thus, if the AI determination section **14** receives, from the AI information confirmation section **13***b*, the input eligibility determination result that the input information is suitable for the recognition processing, the AI determination section **14** performs the recognition processing such as the AI determination based on the input information. The AI determination section **14** outputs the determination result of the AI determination, which is the recognition result of the recognition processing, to the connection destination confirmation section **13***a*. In addition, if the AI determination section **14** receives, from the AI information confirmation section **13***b*, the input eligibility determination result that the input information is not suitable for

the recognition processing, the AI determination section **14** does not perform the recognition processing such as the AI determination based on the input information.

[0032] Note that the AI information confirmation section **13***b* may supply the input information to the AI determination section **14** only in the case where the input eligibility determination result that the input information is suitable for the recognition processing is obtained.

[0033] When receiving the AI determination result from the AI determination section **14**, the connection destination confirmation section **13***a* decides whether to adopt the AI determination result based on the determination result of the device correctness for the device as the transmission source of the input information used for the AI determination. In other words, when having confirmed that the device is correct based on the determination result of the device correctness, the connection destination confirmation section **13***a* adopts the AI determination result and outputs the AI determination result to a display section **30**. Furthermore, when having confirmed that the device is not correct based on the determination result of the device correctness, the connection destination confirmation section **13***a* does not output the AI determination result to the display section **30**.

[0034] The display section **30** displays, on a display screen thereof, the information from the input information confirmation section **13**. When receiving the input of the AI determination result, the display section **30** displays the inputted AI determination result on the display screen. The input information confirmation section **13** may provide the determination result of the device correctness and the determination result of the input eligibility to the display section **30**, to display the results on the display section **30**.

Input Eligibility Determination

[0035] FIG. **2** and FIG. **3** are explanatory diagrams each for describing an example of a determination method for the input eligibility determination by the AI information confirmation section **13***b*.

[0036] The video processor apparatus **20** performs predetermined video signal processing on an image pickup signal obtained by photographing with the endoscope, not shown, to generate a video signal in a predetermined video format in which video parameters such as a resolution, a color gamut, a frame rate are set as appropriate. The video processor apparatus **20** encodes the generated video signal using a predetermined codec such as MPEG-4, H.265/HEVC, then containerizes the encoded video signal in various file formats such as AVI, MOV, WMV, FLV, or other file formats, and transmits the containerized video signal, via an output terminal that conforms to a predetermined transmission standard such as DVI or SDI. Note that the video format of the video signal that can be transmitted is defined according to the transmission standard.

[0037] If the video format that is not suitable for the AI determination is adopted, a highly-reliable AI determination result cannot be obtained. In addition, even if an image in the video format suitable for the AI determination is inputted into the video processor apparatus **20**, there is a case where an image which is not suitable for the AI determination is transmitted to the inspection assistance apparatus **10** due to an erroneous wiring, or other factors. Also in such a case, a highly-reliable AI determination result cannot be obtained.

[0038] An image P**1** in FIG. **2** shows one example of an image suitable for the AI determination by the AI determination section **14**, and the image P**1** is obtained by converting the video signal outputted from the input information output section **22** into an image. The image P**1** includes, in a relatively large range of an entire region of the image, a display area P**1**R for displaying an endoscopic image. The display area P**1**R includes, inside thereof, an endoscopic image P**1**R*a*, an effective image region of which has an octagonal shape by triangular masked regions (filled regions) being formed at four corners of the endoscopic image P**1**R*a*. The endoscopic image P**1**R*a* has a relatively high resolution. The AI determination section **14** performs recognition processing on the endoscopic image P**1**R*a*, to obtain the AI determination result.

[0039] On the other hand, an image P**2** in FIG. **2** shows one example of an image which is not

suitable for the AI determination by the AI determination section **14**. For example, in a case where a type of the endoscope connected to the video processor apparatus **20** is not appropriate, or in a case where the setting of the video processor apparatus **20** is not correct, if the video signal from the input information output section **22** is converted into an image, it is supposed that the image P**2** will be obtained. In other words, the image P**2** includes, in a display area P**1**R occupying a relatively large range of the entire region of the image, an endoscopic image P**1**R*b*, an effective image region of which has an octagonal shape by triangular masked regions (filled regions) being formed at four corners of the endoscopic image P**1**R*b*. The endoscopic image P**1**R*b* has an aspect ratio different from that of the endoscopic image P**1**R*a*. In other words, the endoscopic image P**1**R*a* and the endoscopic image P**1**R*b* are different from each other in the positions in the image based on the video signal as the input information, and the AI determination section **14** may not necessarily be able to obtain a correct AI determination result, even if performing the recognition processing on the endoscopic image P**1**R*b*.

[0040] In addition, in a case where a wrong endoscope is connected to the video processor apparatus **20**, in a case where a wrong setting is performed for the video processor apparatus **20**, or in a case where an image which is not for the AI determination, for example, an image for printing, is inputted into the inspection assistance apparatus **10**, or the like, the resolution of the endoscopic image P**1**R*b* inputted into the inspection assistance apparatus **10** is sometimes lower than the resolution of the endoscopic image P**1**R*a*. In this case, the AI determination section **14** may not necessarily be able to obtain a correct AI determination result, even if performing the recognition processing on the endoscopic image P**1**R*b*. Furthermore, in a case where an image to be outputted to another apparatus, not shown, is erroneously provided to the inspection assistance apparatus **10**, or the like, another image P**2***a* may possibly be superimposed as a PIP (picture-in-picture) on a part of the region of the endoscopic image P**1**R*b*. Also in this case, the AI determination section **14** may not be able to obtain a correct AI determination result.

[0041] The AI information confirmation section **13***b* may determine that the video signal is not the video signal for the recognition processing in at least one of: a case where at least one of an aspect ratio or an image quality of the medical image as the input information is different from an aspect ratio or an image quality of a medical image for learning used for generating an inference model of the AI determination section **14**; or a case where the medical image includes another image superimposed thereon.

[0042] For such a determination, the AI information confirmation section **13***b* may include, for example, a memory, not shown, that stores information related to the features of the image suitable for the AI determination. The AI information confirmation section **13***b* performs an image analysis of the input information and an analysis of metadata accompanying the input information, to compare the information stored in the memory and the input information with regard to the features including an image quality format, a frame rate, the aspect ratio, superimposition of other information, etc., to determine the eligibility of the input information, and thereby obtains the input eligibility determination result. For example, the AI information confirmation section **13***b* may determine the position of the medical image in the image obtained based on the video signal as the input information, and may obtain the input eligibility determination result according to a degree of match between the determined position and the position of the medical image in the image suitable for the AI determination.

[0043] FIG. **2** describes the example in which the eligibility of the input information is determined by the image analysis of the endoscopic image which is the input information, or other analysis. On the other hand, FIG. **3** shows an example in which information directly indicating the eligibility of the input information is included in the input information.

[0044] An image P**3** in FIG. **3** includes, in a display area P**1**R, identification information P**3***a* in a superimposed manner. The identification information P**3***a* indicates that the endoscopic image P**1**R*a* is an image suitable for the AI determination. Note that, in the example shown in FIG. **3**, the

identification information P**3***a* is image information. The identification information P**3***a* is arranged in one of masked regions located at four corners of the display area P**1**R. Therefore, the information of the effective image region of the endoscopic image P**1**R*a* is hardly lost by the identification information P**3***a*.

[0045] As the identification information P**3***a,* for example, a barcode or a QR code (registered trademark) may be used. Note that FIG. **3** shows the example in which the identification information P**3***a* can be visually recognizable, but the one which is not visually recognizable may also be used as the identification information P**3***a*.

[0046] In addition, the identification information P**3***a* may not only be included, as an image, in the image based on the video signal, but also be included in header information of the video signal, or may be metadata, which indicates that the endoscopic image P**1**R*a* is the image suitable for the AI determination, included in the input information.

[0047] The AI information confirmation section **13***b* can determine the eligibility of the input information by confirming the identification information P**3***a*. Thus, the AI information confirmation section **13***b* determines, based on the video signal, whether the video signal is suitable for the recognition processing such as the AI determination.

[0048] Note that the AI information confirmation section **13***b* performs the input eligibility determination at an appropriate timing. For example, the AI information confirmation section **13***b* may perform the input eligibility determination at the time of activating the inspection assistance apparatus **10**, or at the time when the endoscope, not shown, is connected to the video processor apparatus **20**. In addition, the AI information confirmation section **13***b* may perform the input eligibility determination at the time of changing the setting of the video processor apparatus **20** that supplies the input information to the inspection assistance apparatus **10**, or at a predetermined cycle.

[0049] When the AI information confirmation section **13***b* determines that the input information is not suitable for the AI determination based on the input eligibility determination result, the AI information confirmation section **13***b* may generate display information to supply the generated display information to the display section **30**. The display information is for causing warning messages (alert) to be displayed on the display screen of the display section **30**, and examples of the messages include "This is not the target endoscope", "The setting is different", and the like.

Device Correctness Determination

[0050] The connection destination confirmation section **13***a* may include a memory that stores ID information related to a correct device, for determination of the device correctness. The connection destination confirmation section **13***a* may determine the device correctness by comparing the information stored in the memory and the transmission source device information. For example, when endoscopic images are acquired respectively in a plurality of inspection rooms, it can be considered that the endoscopic image, which has been acquired in the inspection room different from the target inspection room, is inputted, as the input information, from the video processor apparatus **20** to the AI information confirmation section **13***b*, due to the erroneous wiring, or other factors. Also in such a case, the AI determination for the input image is obtained correctly. Therefore, if the transmission source device information is not confirmed, the operation assistance is performed based on the endoscopic image obtained in the inspection room different from the target inspection room. In the present embodiment, the connection destination confirmation section **13***a* compares the information stored in the memory and the transmission source device information, to determine the device correctness. If the ID information stored in the memory is different from the ID information from the video processor apparatus **20**, the AI information confirmation section **13***b* determines that the transmission source device is not correct, which prevents an incorrect operation assistance to be provided to the user.

[0051] In addition, as described above, the transmission source device information received by the connection destination confirmation section **13***a* not only include the ID information of the video

processor apparatus **20** but also include the action information and the operation information of the video processor apparatus **20** that include the information on the endoscope to be connected, the information related to the inspection, or the like, and further include the information related to the video format, etc. The connection destination confirmation section **13***a* may determine the device correctness based on the action information, the operation information, and the information related to the video format, etc. Furthermore, the connection destination confirmation section **13***a* may determine the device correctness using the information from the AI information confirmation section **13***b* and the result of the AI determination.

[0052] For example, the connection destination confirmation section **13***a* may determine that the device is not correct, when the AI information confirmation section **13***b* determines that the same image is continuously inputted in a case where the endoscopic image, as the input information, should change according to the change of the operation of the video processor apparatus **20**. The connection destination confirmation section **13***a* may determine that the device is correct, when the AI information confirmation section **13***b* determines that the image has changed. In addition, the connection destination confirmation section **13***a* may determine that the device is correct, when the information of the video format matches the information of the video format determined by the AI information confirmation section **13***b,* and may determine that the device is not correct, when the information of the video format does not match the information of the video format determined by the AI information confirmation section **13***b.* Thus, the connection destination confirmation section **13***a* can determine the device correctness based on the transmission source device information from the video processor apparatus **20** and the image recognition result by the AI information confirmation section **13***b.*

[0053] Furthermore, in the case where the connection destination confirmation section **13***a* receives, for example, the operation information indicating that an endoscopy has been started, when the recognition result that the input image has changed to the image obtained by picking up an image inside a body, that is, the inspection has been started is obtained based on the AI determination by the AI determination section **14**, the connection destination confirmation section **13***a* may determine that the device is correct. In addition, the connection destination confirmation section **13***a* may determine the device correctness depending on, for example, whether the operation information related to the observation mode such as the NBI or the RDI, matches the observation mode in the AI determination result.

[0054] Thus, the video processor apparatus **20**, which is a medical image generation device, can set the observation mode for the endoscope. A determination on whether the endoscopic image obtained under the observation mode set by the video processor apparatus **20** has been supplied, as the input information, to the inspection assistance apparatus **10** is made based on the AI determination result. In other words, the device correctness is determined by determining whether the medical image generation device which is the connection destination of the first communication route and the medical image generation device which is the connection destination of the second communication route are identical to each other.

[0055] Note that when determining that the device is not correct based on the device correctness determination, the connection destination confirmation section **13***a* may output a signal for stopping the action of the AI determination section **14** to the AI determination section **14**.

Various Determinations

[0056] The AI determination section **14** may be configured to be able to perform various AI determinations. For example, the AI determination section **14** may be configured to be able to output the operation guide information of the endoscope as the inspection assistance information. Further, the AI determination section **14** may be configured to be able to output the control information of the automatic insertion endoscope. Furthermore, the AI determination section **14** may be configured to be able to output the identification information of the lesion and the site of the organ.

[0057] When the input information confirmation section **13** obtains the device correctness determination indicating that the transmission source device is not correct or the input eligibility determination indicating that the input information is not suitable for the AI determination, the input information confirmation section **13** may control the AI determination section **14** not to output the inspection assistance information. In addition, in a case where the endoscope connected to the video processor apparatus **20** is an automatic control endoscope which is configured to allow automatic insertion, when the input information confirmation section **13** obtains the device correctness determination indicating that the transmission source device is not correct or the input eligibility determination indicating that the input information is not suitable for the AI determination, the input information confirmation section **13** may be configured to cause an emergency stop apparatus, not shown, to operate for stopping the automatic insertion of the automatic control endoscope.

[0058] Thus, the input information confirmation section **13** outputs the inspection assistance information, when determining that the transmission source device which is the connection destination of the first communication route and the transmission source device which is the connection destination of the second communication route are identical to each other. In addition, the input information confirmation section **13** outputs alert information related to the connection destination of the first communication route and the connection destination of the second communication route, when determining that the transmission source device which is the connection destination of the first communication route and the transmission source device which is the connection destination of the second communication route are different from each other.

Working

[0059] Next, working of the embodiment thus configured will be described with reference to FIGS. **4** to **6**. FIG. **4** is a flowchart showing an AI determination control by the AI information confirmation section **13***b*. FIG. **5** and FIG. **6** are each a flowchart showing the device correctness determination by the connection destination confirmation section **13***a*.

[0060] The endoscope is connected to the video processor apparatus **20**, and the endoscope is driven by the video processor apparatus **20**, to obtain an endoscopic image. For example, in order to perform operation assistance for an endoscopy, the input information output section **22** of the video processor apparatus **20** outputs the endoscopic image obtained with the endoscope to the inspection assistance apparatus **10** via the second communication route. Furthermore, the device information output section **21** of the video processor apparatus **20** outputs the transmission source device information including the action information and the operation information of the video processor apparatus **20**, the information of the video format, etc., of the endoscopic image, to the inspection assistance apparatus **10** via the first communication route.

[0061] In S**1** in FIG. **4**, the AI information confirmation section **13***b* receives the input information, from the input information output section **22** of the video processor apparatus **20**, for the input eligibility determination of the input information. The AI information confirmation section **13***b* performs the image analysis of the medical image which is the received input information and the analysis of the metadata of the input information, to determine whether the input information is the image suitable for the AI determination (S**2**). If the AI information confirmation section **13***b* determines that the input information is the image suitable for the AI determination (YES determination in S**2**), the AI information confirmation section **13***b* outputs, to the AI determination section **14**, the input eligibility determination result for causing the AI determination section **14** to perform the AI determination (S**3**). Furthermore, if the AI information confirmation section **13***b* determines that the input information is not the image suitable for the AI determination (NO determination in S**2**), the AI information confirmation section **13***b* outputs, to the AI determination section **14**, the input eligibility determination result for causing the AI determination section **14** not to perform the AI determination (S**4**).

[0062] In this case, the AI determination section **14** does not perform the AI determination. In

addition, the input information confirmation section **13** displays the warning messages such as "This is not the target endoscope", and "The setting is different" on the display screen of the display section **30**.

[0063] The AI information confirmation section **13***b* provides the input information to the AI determination section **14**, if determining that the input information is suitable for the AI determination. The AI determination section **14** performs the recognition processing on the input information, to obtain the AI determination result. The AI determination section **14** outputs the AI determination result to the input information confirmation section **13**.

[0064] The connection destination confirmation section **13***a* of the input information confirmation section **13** receives, in S**11** in FIG. **5**, the transmission source device information from the device information output section **21** of the video processor apparatus **20** for the device correctness determination of the transmission source device. The connection destination confirmation section **13***a* compares the received transmission source device information with the information stored in the memory, to determine whether the transmission source device that has transmitted the transmission source device information is the target device (S**12**). If the connection destination confirmation section **13***a* determines that the transmission source device is correct (YES determination in S**12**), the connection destination confirmation section **13***a* displays the AI determination result from the AI determination section **14** on the display section **30** (S**13**). On the other hand, if the connection destination confirmation section **13***a* determines that the transmission source device is not correct (NO determination in S**12**), the connection destination confirmation section **13***a* does not display the AI determination result from the AI determination section **14** on the display section **30** (S**14**).

[0065] In the example shown in FIG. **5**, the connection destination confirmation section **13***a* determines the correctness of the transmission source device based on, for example, the ID information of the transmission source device, and the like, to decide whether to display or not to display the AI determination result. However, alternatively, the connection destination confirmation section **13***a* may determine the correctness of the transmission source device by using the outputs of the AI information confirmation section **13***b* and the AI determination section **14**, to decide whether to display or not to display the AI determination result.

[0066] FIG. **6** shows the example in this case. The AI information confirmation section **13***b* of the input information confirmation section **13** determines, in S**31** in FIG. **6**, whether the input information is suitable for the AI determination. If the input information is not suitable for the AI determination, the AI determination is not performed, as described above. If the input information is suitable for the AI determination, the AI determination is performed and the AI determination result is provided to the input information confirmation section **13**.

[0067] The input information confirmation section **13** determines, in S**32**, the correctness of the transmission source device based on the ID information and the like (transmission source determination). If determining that the transmission source device is correct (YES determination in S**33**), the input information confirmation section **13** determines in the next S**34** whether the inspection has been started. In other words, if the input information confirmation section **13** detects that the inspection has been started based on the transmission source device information, the input information confirmation section **13** obtains, from the AI determination section **14**, the AI determination result indicating whether the inspection has been started. If both the transmission source device information and the AI determination result indicate that the inspection has been started (YES determination in S**35**), the input information confirmation section **13** determines the observation mode in the next S**36**.

[0068] When the input information confirmation section **13** detects the observation mode based on the transmission source device information, the input information confirmation section **13** obtains, from the AI determination section **14**, the AI determination result for the observation mode. If both the transmission source device information and the AI determination result indicate the same

observation mode (YES determination in S**37**), the input information confirmation section **13** determines that the transmission source is the correct device in the next S**38**. In this case, the input information confirmation section **13** displays the AI determination result from the AI determination section **14** on the display section **30**.

[0069] On the other hand, if the input information confirmation section **13** obtains NO determination in S**33**, S**35**, or S**37**, the input information confirmation section **13** determines that the transmission source is not the correct device in S**39**. In this case, the input information confirmation section **13** does not display the AI determination result from the AI determination section **14** on the display section **30**. Note that, in this case, the input information confirmation section **13** displays the warning messages such as "This is not the target endoscope" and "The setting is different" on the display screen of the display section **30**.

[0070] Thus, in the present embodiment, determination is made not only on the correctness of the transmission source device but also on the eligibility of the input information, which enables the reliable determination that the input information suitable for the AI determination is inputted from the target device. Such a configuration can prevent an unsuitable AI determination result from being displayed in cases that may occur due to an erroneous connection, etc., where the image which is not suitable for the AI processing is inputted or the AI determination is performed on the input information from the device which is not the target device.

Modified Example

[0071] FIG. **7** is a block diagram showing a modified example. In FIG. **1**, description has been made on the example in which the video processor apparatus **20** transmits the transmission source device information and the input information to the inspection assistance apparatus **10**. In the modified example in FIG. **7**, in the case where the identification information is transmitted in the manner superimposed on the input information, information similar to this identification information is transmitted to the inspection assistance apparatus **10** via a third communication cable C**3** configuring a third communication route.

[0072] A video processor apparatus **20**A is configured by additionally providing an identification information output section **23** to the video processor apparatus **20**. When the identification information output section **23** transmits the input information added with the identification information from the device information output section **21**, the identification information output section **23** outputs identification information having the same content as the identification information added to the input information to the inspection assistance apparatus **10** via the third communication cable C**3**. The device information acquisition section **11** of the inspection assistance apparatus **10** receives the identification information outputted from the identification information output section **23**, to provide the received identification information to the input information confirmation section **13**.

[0073] Note that the example has been shown above, in which the identification information output section **23** outputs the identification information to the inspection assistance apparatus **10** via the third communication cable C**3**. However, the third communication cable C**3** may be omitted, and the identification information may be supplied to the inspection assistance apparatus **10** via the first communication cable C**1**.

[0074] The device information acquisition section **11** of the inspection assistance apparatus **10** provides the received identification information to the AI information confirmation section **13**b. The AI information confirmation section **13**b compares the identification information added to the input information with the identification information received via the third communication cable C**3**. When determining that these pieces of identification information have the same contents, the AI information confirmation section **13**b may determine that the transmission source based on the input information matches the transmission source based on the transmission source device information, and in some cases, may further determine that the input information is suitable for the AI determination.

[0075] Other configurations and working are the same as those in the embodiment shown in FIG. 1.

[0076] According to the modified example thus configured, the pieces of identification information having the same contents are transmitted via the first communication route and the second (or third) communication route, which enables the correctness of the transmission source of the input information to be determined relatively easily.

[0077] The present disclosure is not limited to the above-described embodiments as they are, and it goes without saying to embody the disclosure by modifying the constituent elements in a range without departing from the gist of the disclosure at the practical stage. In addition, various disclosures can be achieved by appropriately combining the plurality of constituent elements disclosed in each of the above-described embodiments. Some of the constituent elements may be deleted from all the constituent elements shown in the embodiment, for example. Furthermore, constituent elements over different embodiments may be appropriately combined.

## Claims

**1**. An inspection assistance system comprising, one or more processors including hardware, the one or more processors being configured to: acquire a video signal including information of a medical image; perform recognition processing based on the video signal, to enable outputting of inspection assistance information for assisting an inspection; acquire identification information included in the video signal, the identification information being different from the information of the medical image; and determine whether the video signal is a video signal for the recognition processing, based on the identification information.

**2**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to: acquire transmission source device information related to a transmission source device via a first communication route connected to the transmission source device, which is a transmission source of the medical image obtained by photographing an image of a subject, to determine whether the transmission source device as a connection destination is suitable, based on the transmission source device information; and acquire the video signal via a second communication route connected to the transmission source device, and determine, based on the acquired video signal, whether the video signal is the video signal for the recognition processing.

**3**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to determine whether the video signal is the video signal for the recognition processing, based on a position of the medical image on an image obtained by converting the video signal.

**4**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to determine whether the video signal is the video signal for the recognition processing based on an aspect ratio of the medical image.

**5**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to determine whether the video signal is the video signal for the recognition processing based on an image quality of the medical image.

**6**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to determine whether the video signal is the video signal for the recognition processing based on whether an image different from the medical image is superimposed on the medical image when the video signal is converted into an image.

**7**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to perform the recognition processing when the video signal is suitable.

**8**. The inspection assistance system according to claim 7, wherein the identification information is a QR code.

**9**. The inspection assistance system according to claim 7, wherein the one or more processors are configured to: acquire information related to a content of the identification information via a first

communication route connected to a transmission source device which is a transmission source of the medical image; acquire the identification information via a second communication route connected to the transmission source device; and determine whether a transmission source device which is a connection destination of the first communication route and a transmission source device which is a connection destination of the second communication route are identical to each other, based on the information related to the content of the identification information acquired via the first communication route and the identification information acquired via the second communication route.

**10**. The inspection assistance system according to claim 2, wherein the transmission source device is a medical image generation device configured to set an observation mode and generate the medical image by observing the subject under the set observation mode, and the one or more processors are configured to: acquire information related to a setting of the observation mode, via the first communication route; acquire the video signal via the second communication route; and determine whether the medical image generation device which is a connection destination of the first communication route and the medical image generation device which is a connection destination of the second communication route are identical to each other based on whether the video signal corresponds to the setting of the observation mode.

**11**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to output an alert when determining that the video signal is not the video signal for the recognition processing.

**12**. The inspection assistance system according to claim 1, wherein the one or more processors are configured: not to output the inspection assistance information when determining that the video signal is not the video signal for the recognition processing; and output the inspection assistance information when determining that the video signal is the video signal for the recognition processing.

**13**. The inspection assistance system according to claim 9, wherein the one or more processors are configured to: output the inspection assistance information when determining that the transmission source device which is the connection destination of the first communication route and the transmission source device which is the connection destination of the second communication route are identical to each other; and output alert information related to the connection destination of the first communication route and the connection destination of the second communication route, when determining that the transmission source device which is the connection destination of the first communication route and the transmission source device which is the connection destination of the second communication route are different from each other.

**14**. The inspection assistance system according to claim 10, wherein the one or more processors are configured to: output the inspection assistance information when determining that the transmission source device which is the connection destination of the first communication route and the transmission source device which is the connection destination of the second communication route are identical to each other; and output alert information related to the connection destination of the first communication route and the connection destination of the second communication route, when determining that the transmission source device which is the connection destination of the first communication route and the transmission source device which is the connection destination of the second communication route are different from each other.

**15**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to: perform the recognition processing by inputting the video signal into a recognition processing apparatus which has performed learning with a medical image for learning; and determine that the video signal is not the video signal for the recognition processing in at least one of: a case where at least one of an aspect ratio or an image quality of the medical image is different from an aspect ratio or an image quality of the medical image for learning; or a case where another image is superimposed on the medical image.

**16**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to output operation guide information of an endoscope as the inspection assistance information.

**17**. The inspection assistance system according to claim 1, wherein the one or more processors are configured to output control information of an automatic control endoscope as the inspection assistance information.

**18**. An inspection assistance method comprising: acquiring a video signal including information of a medical image; acquiring identification information included in the video signal, the identification information being different from the information of the medical image; determining whether the video signal is a video signal for recognition processing based on the identification information; and performing the recognition processing based on the video signal, to output inspection assistance information for assisting an inspection using the medical image.

**19**. A control method for a medical device, the control method comprising: acquiring transmission source device information related to a transmission source device which is a transmission source of a medical image: determining whether the transmission source device as a connection destination is suitable, based on the transmission source device information; acquiring a video signal including information of the medical image; performing recognition processing based on the video signal, to enable outputting of inspection assistance information for assisting an inspection; and determining, based on the video signal, whether the video signal is a video signal for the recognition processing.

**20**. A computer-readable recording medium on which a program is recorded, the program causing a computer to execute: acquiring a transmission source device information related to a transmission source device which is a transmission source of a medical image; determining whether the transmission source device as a connection destination is suitable, based on the transmission source device information; acquiring a video signal including information of the medical image; performing recognition processing based on the video signal, to enable outputting of inspection assistance information for assisting an inspection; and determining, based on the video signal, whether the video signal is a video signal for the recognition processing.
