[0013] Furthermore, the invention includes all racemic mixtures, all their corresponding enantiomers and/or optical isomers.

BACKGROUND OF THE INVENTION

[0014] The NOD-like receptor (NLR) family, pyrin domain-containing protein 3 (NLRP3) inflammasome is a component of the inflammatory process, and its aberrant activity is pathogenic in inherited disorders such as cryopyrin-associated periodic syndromes (CAPS) and complex diseases such as multiple sclerosis, type 2 diabetes, Alzheimer's disease and atherosclerosis.

[0015] NLRP3 is an intracellular signaling molecule that senses many pathogen-derived, environmental and host-derived factors. Upon activation, NLRP3 binds to apoptosis-associated speck-like protein containing a caspase activation and recruitment domain (ASC). ASC then polymerises to form a large aggregate known as an ASC speck. Polymerised ASC in turn interacts with the cysteine protease caspase-1 to form a complex termed the inflammasome. This results in the activation of caspase-1, which cleaves the precursor forms of the proinflammatory cytokines IL-1B and IL-18 (termed pro-IL-1B and pro-IL-18 respectively) to thereby activate these cytokines. Caspase-1 also mediates a type of inflammatory cell death known as pyroptosis. The ASC speck can also recruit and activate caspase-8, which can process pro-IL-1 β and pro-IL-18 and trigger apoptotic cell death.

[0016] Caspase-1 cleaves pro-IL-1 β and pro-IL-18 to their active forms, which are secreted from the cell. Active caspase-1 also cleaves gasdermin-D to trigger pyroptosis. Through its control of the

pyroptotic cell death pathway, caspase-1 also mediates the release of alarmin molecules such as IL-33 and high mobility group box 1 protein (HMGB1). Caspase-1 also cleaves intracellular IL-1R2 resulting in its degradation and allowing the release of IL-1a. In human cells caspase-1 may also control the processing and secretion of IL-37. A number of other caspase-1 substrates such as components of the cytoskeleton and glycolysis pathway may contribute to caspase-1-dependent inflammation.

[0017] NLRP3-dependent ASC specks are released into the extracellular environment where they can activate caspase-1, induce processing of caspase-1 substrates and propagate inflammation.

[0018] Active cytokines derived from NLRP3 inflammasome activation are important drivers of inflammation and interact with other cytokine pathways to shape the immune response to infection and injury. For example, IL-1 β signalling induces the secretion of the pro-inflammatory cytokines IL-6 and TNF. IL-1 β and IL-18 synergise with IL-23 to induce IL-17 production by memory CD4 Th17 cells and by $\gamma\delta$ T cells in the absence of T cell receptor engagement. IL-18 and IL-12 also synergise to induce IFN- γ production from memory T cells and NK cells driving a Th1 response.

[0019] The inherited CAPS diseases Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome (FCAS) and neonatal-onset multisystem inflammatory disease (NOMID) are caused by gain-of-function mutations in NLRP3, thus defining NLRP3 as a critical component of the inflammatory process. NLRP3 has also been implicated in the pathogenesis of a number of complex diseases, notably including metabolic disorders such as type 2 diabetes, atherosclerosis, obesity and gout.

[0020] A role for NLRP3 in diseases of the central nervous system is emerging, and lung diseases have also been shown to be influenced by NLRP3. Furthermore, NLRP3 has a role in the development of liver disease, kidney disease and aging. Many of these associations were defined using Nlrp3.sup.-/- mice, but there have also been insights into the specific activation of NLRP3 in these diseases. In type 2 diabetes mellitus (T2D), the deposition of islet amyloid polypeptide in the pancreas activates NLRP3 and IL-1 β signalling, resulting in cell death and inflammation.

[0021] Several small molecules have been shown to inhibit the NLRP3 inflammasome. Glyburide inhibits IL-1 β production at micromolar concentrations in response to the activation of NLRP3 but not NLRC4 or NLRP1. Other previously characterised weak NLRP3 inhibitors include parthenolide, 3,4-methylenedioxy- β -nitrostyrene and dimethyl sulfoxide (DMSO), although these agents have limited potency and are nonspecific.

[0022] Current treatments for NLRP3-related diseases include biologic agents that target IL-1. These are the recombinant IL-1 receptor antagonist anakinra, the neutralizing IL-1 β antibody canakinumab and the soluble decoy IL-1 receptor rilonacept. These approaches have proven successful in the treatment of CAPS, and these biologic agents have been used in clinical trials for other IL-1 β -associated diseases.

[0023] There is a need to provide compounds with improved pharmacological and/or physiological and/or physicochemical properties and/or those that provide a useful alternative to known compounds.

##STR00005##

[0335] The synthesis of the compounds of formula I of the present invention are synthesized following to the general synthesis depicted in Scheme 1.

[0336] The commercially available building blocks of formula (III) where X is a halogen atom such as bromine, chlorine or iodine more preferably chlorine, can be submitted to a nucleophilic aromatic substitution in order to prepare compounds of formula (IV). The nucleophilic aromatic substitution are carried out with a suitable amine Z—R^{sup.4}, wherein Z and R^{sup.4} have the meaning given for general formula I in the presence of bases as N,N-diisopropylethylamine (DIEA) or trimethylamine which are common and known to the skilled person and/or commercially available. Usually 1,4-dioxane as solvent was used, but solvents such as dimethyl sulfoxide (DMSO) or N-methyl-2-pyrrolidine (NMP) are also suitable. Other similar methods as Buchwald-Hartwig amination could be used. The left-hand side is added to the compound of general formula (IV) to form the compound of formula (V) using a Suzuki cross coupling in the presence of a

palladium catalyst and a boronic acid or boronic pinacol ester such as 4 or 4b according to standard conditions well known to the skilled person. In a final step, the methyl ether group is cleaved with boron tribromide (BBr.sub.3) in dichloromethane delivering the compounds of general formula I. Specific examples are described in more detail for each exemplified compound below.

##STR00006##

[0337] In the case where X is NH.sub.2, the building block of formula (II) was also prepared via a Sandmeyer-type reaction to afford building block (III) wherein X=Cl. Specific examples are described for each exemplified compound below.

[0338] Further, in the cases where the amine Z—R.sup.4 and R.sup.4 contains e.g. a tert-butyloxycarbonyl (BOC) protecting group, an additional deprotection step was carried out either at an initial stage as described for Example 1 using TFA (trifluoroacetic acid) or at a final stage during the methyl ether cleavage.

In the case where R'=H, Va equals to Ib.

Assay Procedures

NLRP3 and Pyroptosis

[0478] It is well established that the activation of NLRP3 leads to cell pyroptosis and this feature plays an important part in the manifestation of clinical disease (Yan-gang Liu et al., Cell Death & Disease, 2017, 8(2), e2579; Alexander Wree et al., Hepatology, 2014, 59(3), 898-910; Alex Baldwin et al., Journal of Medicinal Chemistry, 2016, 59(5), 1691-1710; Ema Ozaki et al., Journal of Inflammation Research, 2015, 8, 15-27; Zhen Xie & Gang Zhao, Neuroimmunology Neuroinflammation, 2014, 1(2), 60-65; Mattia Cocco et al., Journal of Medicinal Chemistry, 2014, 57(24), 10366-10382; T. Satoh et al., Cell Death & Disease, 2013, 4, e644). Therefore, it is anticipated that inhibitors of NLRP3 will block pyroptosis, as well as the release of pro-inflammatory cytokines (e.g. IL-1 β) from the cell.

THP-1 Cells: Culture and Preparation

[0479] THP-1 cells (ATCC #TIB-202) were grown in RPMI containing L-glutamine (Gibco

#11835) supplemented with 1 mM sodium pyruvate (Sigma #S8636) and penicillin (100 units/ml)/streptomycin (0.1 mg/ml) (Sigma #P4333) in 10% Fetal Bovine Serum (FBS) (Sigma #F0804). The cells were routinely passaged and grown to confluency (~10^{sup.6} cells/ml). On the day of the experiment, THP-1 cells were harvested and resuspended into RPMI medium (without FBS). The cells were then counted and viability (>90%) checked by Trypan blue (Sigma #T8154). Appropriate dilutions were made to give a concentration of 625,000 cells/ml. To this diluted cell solution was added LPS (Sigma #L4524) to give a 1 µg/ml Final Assay Concentration (FAC). 40 µl of the final preparation was aliquoted into each well of a 96-well plate. The plate thus prepared was used for compound screening.

THP-1 Cells Pyroptosis Assay

[0480] The following method step-by-step assay was followed for compound screening. [0481] 1. Seed THP-1 cells (25,000 cells/well) containing 1.0 µg/ml LPS in 40 µl of RPMI medium (without FBS) in 96-well, black walled, clear bottom cell culture plates coated with poly-D-lysine (VWR #734-0317) [0482] 2. Add 5 µl compound (8 points half-log dilution, with 10 µM top dose) or vehicle (DMSO 0.1% FAC) to the appropriate wells [0483] 3. Incubate for 3 hours at 37° C., 5% CO₂ [0484] 4. Add 5 µl nigericin (Sigma #N7143) (FAC 5 µM) to all wells [0485] 5. Incubate for 1 hr at 37° C., 5% CO₂ [0486] 6. At the end of the incubation period, spin plates at 300×g for 3 mins and remove supernatant [0487] 7. Then add 50 µl of resazurin (Sigma #R7017) (FAC 100 µM resazurin in RPMI medium without FBS) and incubate plates for a further 1-2 hours at 37° C. and 5% CO₂ [0488] 8. Plates were read in an Envision reader at Ex 560 nm and Em 590 nm [0489] 9. IC₅₀ data is fitted to a non-linear regression equation (log inhibitor vs response-variable slope 4-parameters)

[0490] The results of the pyroptosis assay are summarised in Table 1 below as THP IC₅₀.

Human Whole Blood IL-1β Release Assay

[0491] For systemic delivery, the ability to inhibit NLRP3 when the compounds are present within the bloodstream is of great importance. For this reason, the NLRP3 inhibitory activity of a number of compounds in human whole blood was investigated in accordance with the following protocol. [0492] Human whole blood in Li-heparin tubes was obtained from healthy donors from a volunteer donor panel. [0493] 1. Plate out 80 µl of whole blood containing 1 µg/ml of LPS in 96-well, clear bottom cell culture plate (Corning #3585) [0494] 2. Add 10 µl compound (8 points half-log dilution with 10 µM top dose) or vehicle (DMSO 0.1% FAC) to the appropriate wells [0495] 3. Incubate for 3 hours at 37° C., 5% CO₂ [0496] 4. Add 10 µl nigericin (Sigma #N7143) (10 µM FAC) to all wells [0497] 5. Incubate for 1 hr at 37° C., 5% CO₂ [0498] 6. At the end of the incubation period, spin plates at 300×g for 5 mins to pellet cells and remove 20p of supernatant and add to 96-well v-bottom plates for IL-1β analysis (note: these plates containing the supernatants can be stored at -80° C. to be analysed at a later date) [0499] 7. IL-1β was measured according to the manufacturer protocol (Perkin Elmer-AlphaLisa IL-1 Kit AL220F-5000) [0500] 8. IC₅₀ data is fitted to a non-linear regression equation (log inhibitor vs response-variable slope 4-parameters) [0501] The results of the human whole blood assay are summarised in Table 1 below as HWB IC₅₀.

Herg Screening Assay

Cells

[0502] The CHO crelox hERG cell line (ATCC reference Nr. PTA-6812, female Chinese hamster cells) was generated and validated at Roche. Ready-to-use frozen instant CHO-hERG cells were cryopreserved at Evotec (Germany) and used directly in the experiments.

Experimental Solutions

[0503] The extracellular solution contains (in mM): NaCl 150; KCl 4; CaCl₂ 1; MgCl₂ 1; HEPES 10; pH 7.2-7.4 with NaOH, osmolarity 290-330 mOsm. The internal solution contains (in mM): KCl, 10; KF, 100; NaCl, 10; HEPES, 10; EGTA, 20; pH=7.0-7.4 with KOH, osmolarity 260-300 mOsm.

Electrophysiology

[0504] The effects of a compound on hERG K⁺-currents parameters will be evaluated at 2 concentrations in at least 4 cells.

[0505] The hERG test is performed using automated patch clamp system SynchroPatch® 384 (Nanon Technologies GmbH, Germany). K⁺ currents are measured with the patch-voltage-clamp technique in the whole-cell configuration at 35-37° C.

[0506] Cells were held at a resting voltage of -80 mV and they were stimulated by a voltage pattern shown in FIG. 1 to activate hERG channels and conduct outward I_{hERG} current, at a stimulation frequency of 0.1 Hz (6 bpm)

Data Analysis

[0507] The amplitudes of I_{hERG} were recorded in each concentration of drug and they were compared to the vehicle control values (taken as 100%) to define fractional blocks. The concentration-response data were fitted with the following relationship:

TABLE-US-00001 [00001] $I(C) = \frac{100}{1 + (C/IC_{50})^h}$ where C is the concentration, IC₅₀ is the concentration producing 50% block h is the Hill coefficient.

[0508] Concentration-response curves were fitted by non-linear regression analysis using EworkBook suite (ID Business Solutions Ltd, UK). Data fit was done with the 4 Parameter Logistic Model (fit=(A+(B/(1+((x/C){circumflex over ()})D))), where A=0 and B=100).
