Background/Summary

RELATED APPLICATIONS (1) This patent application is the U.S. national stage entry, under 35 U.S.C. § 371, of International Application Number PCT/US2020/044097, filed Jul. 29, 2020, which claims priority to U.S. Provisional Application No. 62/880,032, filed Jul. 29, 2019, the entire contents of each of which are hereby incorporated by reference.

TECHNICAL FIELD

(1) The present disclosure relates to compounds, compositions, and methods for treating MYC-related cancers, such as ovarian cancer, breast cancer, colorectal cancer, pancreatic cancer, gastric cancer, stomach cancer, lung cancer, cervical cancer, uterine cancer, cancers of the blood, and cancers of the lymphatic system.

BACKGROUND

(2) The MYC oncogenes (c-, N-, and L-MYC) encode a family of related transcription factors (hereafter “MYC”) that are overexpressed in the majority of malignancies and contribute to ~100,000 cancer related deaths annually in the USA alone. MYC drives tumorigenesis by dimerizing with its obligate partner MAX to form a sequence-specific transcription factor that controls the expression of genes linked to cell growth, metabolism, proliferation, and genome instability (Tansey 2014). Unlike many oncogenes, activation of MYC is not dependent on changes to its protein sequence, but instead results from mutations that increase MYC expression, either by altering MYC gene copy number or location, or by subverting regulatory mechanisms that normally restrict MYC accumulation. The advantages of MYC overexpression to a cancer cell—together with the myriad of ways this can occur—means that increased MYC levels are common in cancer, and has led to the concept that loss of control of MYC underlies the etiology of all malignancies (Conacci-Sorrell et al. 2014).

(3) The pervasive involvement of MYC in cancer has fueled interest in the notion that MYC can be targeted to treat malignancies. It is clear that attenuating MYC expression or activity in the context of an existing cancer promotes tumor regression in mice (Conacci-Sorrell et al. 2014), even in cases where MYC is not the primary oncogenic driver (Soucek et al. 2013). A number of strategies have been developed to mitigate MYC overexpression in cancer (Delmore et al. 2011), or to interfere with processes hijacked by MYC in the malignant state (Dang 2011), but in terms of directly blocking MYC function, there appears to be few if any viable options. Indeed, the obvious route to direct MYC inhibition—disrupting interaction with MAX—is daunting, as the MYC:MAX interface is large and tight, and not readily amenable to inhibition by drug-like molecules. Accordingly, there exists a need for small molecule modulators of MYC that selectively interact with and disrupt the oncogenic activity of MYC.

(4) Recently, it emerged that target gene recognition by MYC does not solely depend on the DNA-binding characteristics of MYC:MAX dimers, and that additional factors can facilitate MYC recruitment to chromatin. Modeling reveals that upwards of 90% of MYC binding events cannot be accounted for in terms of the affinity of MYC:MAX dimers for DNA (Lorenzin et al. 2016), and that even weak interactions ($K_{sub.d} \sim 10 \mu\text{M}$) with chromatin resident-proteins could stabilize MYC:MAX dimers and explain MYC binding patterns observed in vivo. If the factors that facilitate recruitment of MYC to chromatin can be identified, they could serve as novel therapeutic targets for blocking this basic MYC function in cancer cells. One such factor that facilitates recruitment of MYC to chromatin is the WD40-repeat protein WDR5 (Thomas et al. 2015).

(5) WD40-repeat proteins are a ubiquitous family of scaffolding proteins, containing β -propeller domains that form donut-shaped structures which participate in many multi-protein complexes. WDR5 scaffolds the assembly of protein complexes related to chromatin structure and epigenetic modifications. Like most WD40-repeat proteins, WDR5 is involved in many direct and indirect protein-protein interactions, but all known direct partners of WDR5 interact through one of two sites, referred to as the “WDR5-interaction” (WIN) site and the “WDR5 binding motif” (WBM) site.

(6) The interaction of c-MYC and L-MYC with the WBM site of WDR5 has been previously described (Thomas et al., 2015), and it has been further reported that WDR5 is a crucial partner in the facilitated recruitment of MYC to chromatin. N-MYC also binds WDR5 (Sun et al. 2015). Co-immunoprecipitation and X-ray crystallography confirmed that WDR5 binds to the central-portion of MYC via the conserved 'MYC box' MbIIIb motif that is invariant in all MYC proteins throughout evolution. Within MbIIIb is a consensus WBM (sequence "EEIDVV") that engages the shallow hydrophobic WBM site on WDR5. Mutations in MYC that disrupt interaction with WDR5 disrupt binding of MYC to chromatin and disable its tumorigenic potential in mice, defining the MYC-WDR5 interaction as critical for MYC-driven cancer. The identification of WDR5 as a universal MYC co-factor, and the characterization of a defined WDR5-MYC interaction site, presents a potentially tractable target for small molecule inhibition of MYC-driven tumors.

SUMMARY

(7) Disclosed herein are inhibitors or disruptors of the WDR5-MYC protein-protein interaction. The inhibitors can be compounds of formula (I) or (II). Compounds of formula (I) or (II) may bind to the WBM site of WDR5 and prevent MYC from binding to WDR5. Targeting the WBM site of WDR5 with a small molecule inhibitor may disrupt the association of MYC with WDR5 and block MYC's recruitment to key target genes required for the onset or maintenance of the tumorigenic state. As a result, inhibitors of the WDR5-MYC protein-protein interaction can result in inhibition of oncogenic processes governed by MYC and provide therapeutic benefits for cancers caused by MYC dysregulation. Overexpression and dysregulation of MYC has been implicated in a number of different cancers including, but not limited to, ovarian cancer, breast cancer, colorectal cancer, pancreatic cancer, gastric cancer, uterine cancer, and cancers of the blood. Accordingly, compounds of formula (I) or (II) can be used to treat cancers associated with MYC by preventing association of MYC with WDR5.

(20) The term “hydroxyl” or “hydroxy,” as used herein, means an —OH group.

(21) The term “hydroxyalkyl,” as used herein, means at least one —OH group, is appended to the parent molecular moiety through an alkylene group, as defined herein.

(22) Terms such as “alkyl,” “cycloalkyl,” “alkylene,” etc. may be preceded by a designation indicating the number of atoms present in the group in a particular instance (e.g., “C.sub.1-4alkyl,” “C.sub.3-6cycloalkyl,” “C.sub.1-4alkylene”). These designations are used as generally understood by those skilled in the art. For example, the representation “C” followed by a subscripted number indicates the number of carbon atoms present in the group that follows. Thus, “C.sub.3alkyl” is an alkyl group with three carbon atoms (i.e., n-propyl, isopropyl). Where a range is given, as in “C.sub.1-4,” the members of the group that follows may have any number of carbon atoms falling within the recited range. A “C.sub.1-4 alkyl,” for example, is an alkyl group having from 1 to 4 carbon atoms, however arranged (i.e., straight chain or branched).

(23) The term “substituted” refers to a group that may be further substituted with one or more non-hydrogen substituent groups. Substituent groups may include, for example, halogen, =O (oxo), =S (thioxo), cyano, nitro, fluoroalkyl, alkoxyfluoroalkyl, fluoroalkoxy, alkyl, alkenyl, alkynyl, haloalkyl, haloalkoxy, heteroalkyl, cycloalkyl, cycloalkenyl, aryl, heteroaryl, heterocycle, cycloalkylalkyl, heteroarylalkyl, arylalkyl, hydroxy, hydroxyalkyl, alkoxy, alkoxyalkyl, alkylene, aryloxy, phenoxy, benzyloxy, amino, alkylamino, acylamino, aminoalkyl, arylamino, sulfonylamino, sulfinylamino, sulfonyl, alkylsulfonyl, arylsulfonyl, aminosulfonyl, sulfinyl, —COOH, ketone, amide, carbamate, and acyl.

(24) For compounds described herein, groups and substituents thereof may be selected in accordance with permitted valence of the atoms and the substituents, such that the selections and substitutions result in a stable compound, e.g., which does not spontaneously undergo transformation such as by rearrangement, cyclization, elimination, etc.

(25) For the recitation of numeric ranges herein, each intervening number there between with the same degree of precision is explicitly contemplated. For example, for the range of 6-9, the numbers 7 and 8 are contemplated in addition to 6 and 9, and for the range 6.0-7.0, the number 6.0, 6.1, 6.2, 6.3, 6.4, 6.5, 6.6, 6.7, 6.8, 6.9, and 7.0 are explicitly contemplated.

(105) The compound may exist as a stereoisomer wherein asymmetric or chiral centers are present. The stereoisomer is "R" or "S" depending on the configuration of substituents around the chiral carbon atom. The terms "R" and "S" used herein are configurations as defined in IUPAC 1974 Recommendations for Section E, Fundamental Stereochemistry, in Pure Appl. Chem., 1976, 45: 13-30. The disclosure contemplates various stereoisomers and mixtures thereof and these are specifically included within the scope of this invention. Stereoisomers include enantiomers and diastereomers, and mixtures of enantiomers or diastereomers. Individual stereoisomers of the compounds may be prepared synthetically from commercially available starting materials, which contain asymmetric or chiral centers or by preparation of racemic mixtures followed by methods of resolution well-known to those of ordinary skill in the art. These methods of resolution are exemplified by (1) attachment of a mixture of enantiomers to a chiral auxiliary, separation of the resulting mixture of diastereomers by recrystallization or chromatography and optional liberation of the optically pure product from the auxiliary as described in Furniss, Hannaford, Smith, and Tatchell, "Vogel's Textbook of Practical Organic Chemistry", 5th edition (1989), Longman Scientific & Technical, Essex CM20 2JE, England, or (2) direct separation of the mixture of optical enantiomers on chiral chromatographic columns or (3) fractional recrystallization methods.

(106) It should be understood that the compound may possess tautomeric forms, as well as geometric isomers, and that these also constitute an aspect of the invention.

(107) The present disclosure also includes an isotopically-labeled compound, which is identical to those recited in formula (I) or (II), but for the fact that one or more atoms are replaced by an atom having an atomic mass or mass number different from the atomic mass or mass number usually found in nature. Examples of isotopes suitable for inclusion in the compounds of the invention are hydrogen, carbon, nitrogen, oxygen, phosphorus, sulfur, fluorine, and chlorine, such as, but not limited to, ^2H , ^3H , ^{13}C , ^{14}C , ^{15}N , ^{18}O , ^{17}O , ^{31}P , ^{32}P , ^{35}S , ^{18}F , and ^{36}Cl , respectively. Substitution with heavier isotopes such as deuterium, i.e., ^2H , can afford certain therapeutic advantages resulting from greater metabolic stability, for example increased in vivo half-life or reduced dosage requirements and, hence, may be preferred in some circumstances. The compound may incorporate positron-emitting isotopes for medical imaging and positron-emitting tomography (PET) studies for determining the distribution of receptors. Suitable positron-emitting isotopes that can be incorporated in compounds of formula (I) or (II) are ^{11}C , ^{13}N , ^{15}O , and ^{18}F . Isotopically-labeled compounds of formula (I) or (II) can generally be prepared by conventional techniques known to those skilled in the art or by processes analogous to those described in the accompanying Examples using appropriate isotopically-labeled reagent in place of non-isotopically-labeled reagent.

(108) The disclosed compounds may exist as pharmaceutically acceptable salts. The term “pharmaceutically acceptable salt” refers to salts or zwitterions of the compounds which are water or oil-soluble or dispersible, suitable for treatment of disorders without undue toxicity, irritation, and allergic response, commensurate with a reasonable benefit/risk ratio and effective for their intended use. The salts may be prepared during the final isolation and purification of the compounds or separately by reacting an amino group of the compounds with a suitable acid. For example, a compound may be dissolved in a suitable solvent, such as but not limited to methanol and water and treated with at least one equivalent of an acid, like hydrochloric acid. The resulting salt may precipitate out and be isolated by filtration and dried under reduced pressure. Alternatively, the solvent and excess acid may be removed under reduced pressure to provide a salt. Representative salts include acetate, adipate, alginate, citrate, aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, camphorate, camphorsulfonate, digluconate, glycerophosphate, hemisulfate, heptanoate, hexanoate, formate, isethionate, fumarate, lactate, maleate, methanesulfonate, naphthylenesulfonate, nicotinate, oxalate, pamoate, pectinate, persulfate, 3-phenylpropionate, picrate, oxalate, maleate, pivalate, propionate, succinate, tartrate, trichloroacetate, trifluoroacetate, glutamate, para-toluenesulfonate, undecanoate, hydrochloric, hydrobromic, sulfuric, phosphoric and the like. The amino groups of the compounds may also be quaternized with alkyl chlorides, bromides and iodides such as methyl, ethyl, propyl, isopropyl, butyl, lauryl, myristyl, stearyl and the like.

(109) Basic addition salts may be prepared during the final isolation and purification of the disclosed compounds by reaction of a carboxyl group with a suitable base such as the hydroxide, carbonate, or bicarbonate of a metal cation such as lithium, sodium, potassium, calcium, magnesium, or aluminum, or an organic primary, secondary, or tertiary amine. Quaternary amine salts can be prepared, such as those derived from methylamine, dimethylamine, trimethylamine, triethylamine, diethylamine, ethylamine, tributylamine, pyridine, N,N-dimethylaniline, N-methylpiperidine, N-methylmorpholine, dicyclohexylamine, procaine, dibenzylamine, N,N-dibenzylphenethylamine, 1-phenamine and N,N'-dibenzylethylenediamine, ethylenediamine, ethanolamine, diethanolamine, piperidine, piperazine, and the like.

B. GENERAL SYNTHESIS

(112) Compounds of formula (I) or (II) may be prepared by synthetic processes or by metabolic processes. Preparation of the compounds by metabolic processes includes those occurring in the human or animal body (in vivo) or processes occurring in vitro.

(113) The compounds of the present disclosure can be prepared in a number of ways well known to one skilled in the art of organic synthesis. The compounds of the present disclosure can be synthesized using the methods described below, together with synthetic methods known in the art of synthetic organic chemistry, or variations thereon as appreciated by those skilled in the art. Preferred methods include, but are not limited to, those described below. All references cited herein are hereby incorporated in their entirety by reference as to the subject matter referenced herein. Compounds of formula (I) or (II) may be also prepared by metabolic processes. Preparation of the compounds by metabolic processes includes those occurring in the human or animal body (in vivo) or processes occurring in vitro.

(114) The compounds of the disclosure may be prepared using the exemplary reactions and techniques described in this section. The reactions are performed in solvents appropriate to the reagents and materials employed and are suitable for the transformations being effective. Also, in the description of the synthetic methods described below, it is to be understood that all proposed reaction conditions, including solvent, reaction atmosphere, reaction temperature, duration of the experiment and workup procedures, are chosen to be the conditions standard for that reaction, which should be readily recognized by one skilled in the art. One having ordinary skill in the art may adjust one or more of the conditions described herein. One skilled in the art of organic synthesis understands that the functionality present on various portions of the edict molecule must be compatible with the reagents and reactions proposed. Not all compounds of the disclosure falling into a given class may be compatible with some of the reaction conditions required in some of the methods described. Such restrictions to the substituents, which are compatible with the reaction conditions, will be readily apparent to one skilled in the art and alternate methods can be used.

(115) Compounds of the current invention can be readily synthesized using a number of techniques known to those of skill in the art. In one convenient procedure, compounds of the current invention can be prepared by reacting an appropriately substituted aniline with an appropriately substituted sulfonyl chloride.

(116) ##STR00012##

(117) It will be recognized by those of ordinary skill in the art that the anilines and sulfonyl chlorides required for this procedure can be prepared using a number of techniques. In one such

technique, appropriately substituted aromatic compounds can be reacted with chlorosulfonic acid, as shown in Scheme 1, and as exemplified by General Procedure A.

(118) ##STR00013##

(119) General Procedure A (Chlorosulfonation). Chlorosulfonic acid (7-10 eq) was cooled to -10° C. in a bath of ice/saturated aqueous NaCl. To this was added the corresponding aromatic species (1 eq), portion-wise, as required; the mixture was stirred for 1-16 h. The mixture was quenched by careful addition to a slurry of ice (with or without the addition of saturated aqueous NaCl) and CH₂Cl₂, extracting with CH₂Cl₂. The crude material was purified by ISCO flash chromatography or used directly with no purification.

(120) Likewise, those of skill in the art will recognize that the anilines required to synthesize compounds of the present invention can be prepared using several known techniques. In one such convenient procedure, appropriately substituted aromatic compounds can be reacted with nitric acid in the presence of sulfuric and in an appropriate solvent, such as dichloromethane, dichloroethane, or the like. Subsequently, the resulting nitro aromatic compound can be converted to the aniline using many different conditions. One such set of conditions includes exposing the compound, in an appropriate solvent, such as ethyl acetate, methanol, isopropanol, or the like, to an atmosphere of hydrogen gas and in the presence of an appropriate catalyst, such as palladium on carbon, platinum on carbon, or the like. Alternatively, the nitroaromatic can be converted to the corresponding aniline by treatment with iron powder in an appropriate solvent, such as acetic acid. These procedures are shown in Scheme 2 and exemplified with General Procedures B followed by C or D.

(121) ##STR00014##

(122) General Procedure B (Nitration). A 0.2-0.4 M solution containing the appropriate reactant (1 eq) in CH₂Cl₂ was cooled to -20° C. or to 0° C. in an ice/water bath. To this was added a pre-mixed solution of HNO₃ (conc., 1.5-1.6 eq) and H₂SO₄ (conc., 1.5-2.7 eq). The mixture was stirred for 1-16 h, allowing to warm to r.t., then poured over ice water and extracted with CH₂Cl₂. The crude material was purified by ISCO flash chromatography.

(123) General Procedure C (Hydrogenation). To a solution containing the appropriate reactant (1 eq) and EtOAc (with or without added MeOH), was added Pd/C (5% C by wt., 10 mol %) and the mixture was stirred under a H₂ atmosphere for 16 h. The mixture was filtered through celite, concentrated, and purified by ISCO flash chromatography if required.

(124) General Procedure D (Nitro Reduction). To a mixture containing the corresponding nitrobenzene and HOAc, iron powder was added. The reaction mixture was allowed to stir overnight at room temperature, then filtered and concentrated. The crude material was purified by ISCO chromatography or preparative HPLC.

(125) Some compounds of the current invention, in which the aniline is substituted with an ester, can be conveniently prepared by first reacting an appropriately substituted aniline with an appropriately substituted sulfonyl chloride in an appropriate solvent, such as dichloromethane, tetrahydrofuran, or the like, and using an appropriate base, such as pyridine, triethyl amine, diisopropylethyl amine, or the like. Then, the ester can be converted to a compound of the present invention by reacting the ester-substituted compound with a reagent capable of hydrolyzing the ester, such as lithium hydroxide, sodium hydroxide, or the like, in a suitable solvent, such as ether, tetrahydrofuran, methanol, water, or the like. This procedure is shown in Scheme 3 and exemplified by General Procedures E and F.

(126) ##STR00015##

(127) General Procedure E (Sulfonamide Coupling). To a solution containing the corresponding aniline (1-1.5 eq), sulfonyl chloride (1.0-1.5 eq), and CH₂Cl₂, at 0.2 M at r.t., was added pyridine (3 eq). The mixture was allowed to stir for 1-16 h, then concentrated under reduced pressure and purified by ISCO flash chromatography or preparative HPLC, unless otherwise stated.

(128) General Procedure F (Ester Hydrolysis). A $\sim$ 0.2 M solution containing the corresponding ester

(1 eq) and THF or a THF/MeOH mixture was added a 2 M aqueous solution of LiOH or a 1 M aqueous solution of NaOH. The reaction mixture was heated at 45-65° C. for 1-16 h, unless otherwise stated. The mixture was acidified with hydrochloric acid, extracted with EtOAc and washed with brine. The crude material was purified by preparative HPLC.

(129) Some compounds of the present invention can be conveniently synthesized by reacting an ester-containing compound with an appropriate amine in a suitable solvent, such as tetrahydrofuran, dioxane, dimethylsulfoxide, or the like, and at a temperature of 30-150° C., optionally in the presence of a suitable base, such as potassium carbonate, trimethylamine, diisopropylethyl amine, or the like. Similar compounds can also be conveniently prepared by converting an acid-containing compound to an amide-containing compound using a suitable amine. Those of skill in the art will recognize that there are numerous ways to accomplish this transformation. Methods useful for the preparation of compounds of the current invention which contain an amide include treating an appropriately substituted acid-containing compound with a suitable coupling agent, such as EDC, HATU, or Pybrop, in a suitable solvent, such as dichloromethane, tetrahydrofuran, dimethylformamide, or the like, in the presence of an appropriately substituted amine, and using a suitable base, such as triethyl amine or diisopropyl amine. These procedures for converting an ester- or acid-containing compound to an amide-containing compound are shown in Scheme 4 and exemplified by General Procedures G, H, I, and J.

(130) ##STR00016##

A 0.2 M solution containing the corresponding carboxylic acid (1 eq) and DIPEA (3 eq) in CH.sub.2Cl.sub.2 was cooled to 0° C. in an ice/water bath. HATU (1.5 eq) was added and the reaction mixture was stirred for 30 mins, followed by the addition of amine (1.1 eq). The solution was warmed to r.t. and stirred for 16 h, then diluted with CH.sub.2Cl.sub.2 and washed with H.sub.2O. Crude product was purified by ISCO flash chromatography or preparative HPLC.

(138) The synthesis of some compounds of the present invention requires anilines with specific substitutions that are not readily available. The preparation of many of these can be conveniently

accomplished via the reaction of an appropriately substituted aromatic halide, such as a bromide, with an appropriately substituted boronic acid or boronate ester in the presence of an appropriate palladium catalyst and suitable ligand, such as triphenyl phosphine, dppf, Xantphos, or the like, in an appropriate solvent, such as tetrahydrofuran, dioxane, water, or the like, and in the presence of a suitable base, such as sodium carbonate, cesium carbonate, or potassium phosphate, at a temperature of 50-150° C. The anilines can be prepared from the resulting nitro aromatic using many different conditions. One such set of conditions includes exposing the compound in an appropriate solvent, such as ethyl acetate, methanol, isopropanol, or the like to an atmosphere of hydrogen gas and in the presence of an appropriate catalyst, such as palladium on carbon, platinum on carbon, or the like. Alternatively, the nitroaromatic can be converted to the corresponding aniline by treatment with iron powder in an appropriate solvent, such as acetic acid. The reaction mixture was heated at 80° C. for 1-16 h. The cooled mixture was filtered through celite, washing with CH.sub.2Cl.sub.2, and purified by ISCO flash chromatography.

(141) The synthesis of some compounds of the present invention requires an aniline substituted with a cyclopropyl ring. These anilines can be prepared by reacting an appropriately substituted aromatic halide, such as a bromide, with cyclopropyl boronic acid, in the presence of an appropriate palladium catalyst and a suitable ligand, such as triphenyl phosphine, tricyclohexylphosphine, dppf, Xantphos, or the like, in an appropriate solvent, such as tetrahydrofuran, dioxane, toluene, water, or the like, and in the presence of a suitable base, such as sodium carbonate, cesium carbonate, or potassium phosphate, at a temperature of 50-150° C. This procedure is shown in Scheme 5b, and exemplified by General Procedure M. Such anilines can be reacted with appropriately substituted sulfonyl chlorides to synthesize compounds of the present invention.

(143) General Procedure M (Suzuki Coupling—Cyclopropylboronic Acid). A mixture containing the intermediate bromide (1 eq), cyclopropylboronic acid (1.2 eq), Pd(OAc).sub.2 (0.05 eq), PCy.sub.3.Math.HBF.sub.4 (0.1 eq), and K.sub.3PO.sub.4 (2.5 eq) in a mixture of toluene:H.sub.2O (10:1, 0.2 M final concentration) was heated at 110° C. for 1-16 h. The cooled reaction mixture was filtered through celite, washed with CH.sub.2Cl.sub.2, and purified by ISCO flash chromatography.

(144) Some anilines required for the synthesis of some compounds of the present invention can be prepared by reacting an appropriately substituted aromatic bromide with phenyl formate in the presence of an appropriate palladium catalyst and a suitable ligand, such as tricyclohexylphosphine, tributylphosphine, or Xantphos, in an appropriate solvent, such as toluene, tetrahydrofuran, acetonitrile, or the like, at a temperature of 50-150° C. and using an appropriate base, such as triethylamine, cesium carbonate, potassium phosphate, or the like. The phenol can be revealed by reacting the resulting aromatic ether with boron tribromide in a suitable solvent, such as dichloromethane, dichloroethane, toluene, or the like. The phenol resulting from this set of procedures can then be reacted with nitric acid in the presence of sulfuric and in an appropriate solvent, such as dichloromethane, dichloroethane, or the like. Subsequently, the resulting nitro aromatic compound can be converted to the aniline using many different conditions. One such set of conditions includes exposing the compound in an appropriate solvent, such as ethyl acetate,

methanol, isopropanol, or the like to an atmosphere of hydrogen gas and in the presence of an appropriate catalyst, such as palladium on carbon, platinum on carbon, or the like. Alternatively, the nitroaromatic can be converted to the corresponding aniline by treatment with iron powder in an appropriate solvent, such as acetic acid. These procedures are shown in Scheme 6 and exemplified with General Procedures N, O, B, and C or D. Such anilines can be reacted with appropriately substituted sulfonyl chlorides to synthesize compounds of the present invention.

(148) Those of skill in the art will recognize that there are many ways to prepare intermediates needed to synthesize the anilines necessary to synthesize compounds of the present invention. In some instances, an appropriately substituted hydroxybenzoic acid can be converted to the corresponding methyl ester using a variety of techniques. One such technique involves the reaction of the carboxylic acid with trimethylsilyldiazomethane in an appropriate solvent, such as ether, tetrahydrofuran, water, or the like. Subsequently, the free phenol can be masked using a number of protecting groups that will be evident to those of ordinary skill. One such protecting group is a benzyl ether, which can be installed by reacting the phenol with benzyl bromide in an appropriate solvent, such as tetrahydrofuran, acetonitrile, toluene, or the like, and in the presence of a suitable base, such as triethyl amine, potassium carbonate, sodium hydride, or the like. The aromatic compound produced in this way can be brominated using reagents evident to those of skill in the art. One such brominating reagent is N-bromosuccinimide. Those of skill in the art will recognize that there are numerous ways to remove the benzyl group. One such method involves the reaction of the benzyl ether with boron tribromide in a suitable solvent, such as dichloromethane, dichloroethane, toluene, or the like. The phenol resulting from this set of procedures can then be reacted with nitric acid in the presence of sulfuric acid in an appropriate solvent, such as dichloromethane, dichloroethane, or the like. Subsequently, the resulting nitro aromatic compound can be converted to the aniline using many different conditions. One such set of conditions includes exposing the compound in an appropriate solvent, such as ethyl acetate, methanol, isopropanol, or the like to an atmosphere of hydrogen gas and in the presence of an appropriate catalyst, such as palladium on carbon, platinum on carbon, or the like. Alternatively, the nitroaromatic can be converted to the corresponding aniline by treatment with iron powder in an appropriate solvent, such as acetic acid. These procedures are shown in Scheme 7 and exemplified with General Procedures P, Q, L or M, B, O, and C or D. (166) Appropriately substituted anilines required for the synthesis of compounds of the present invention can be conveniently prepared by reacting an appropriately substituted aromatic iodide or bromide with sodium methanesulfinate in an appropriate solvent such as dimethylsulfoxide or dimethylformamide, in the presence of a suitable catalyst, such as copper iodide, an appropriate ligand, such as proline, and using a suitable base, such as sodium hydroxide, at a temperature of $40\text{--}100^\circ\text{C}$. In the instances in which the resulting aromatic compounds are substituted with an appropriate ester, the corresponding aniline can be synthesized by initial reaction with diphenylphosphoryl azide along with tert-butanol in an appropriate solvent, such as dioxane, dimethoxyethane, and the like, and at a temperature of $50\text{--}110^\circ\text{C}$. Those of skill in the art will recognize that this reaction produces a tert-butyl carbamate, which can be converted to the corresponding aniline by treatment with a number of acid reagents, such as hydrochloric acid or trifluoroacetic acid, in an appropriate solvent, such as dichloromethane, dichloroethane, or the like. These procedures are shown in Scheme 11 and exemplified by General Procedures S and X. Such anilines can be reacted with appropriately substituted sulfonyl chlorides to synthesize compounds of the present invention.

(168) General Procedure X (Curtius rearrangement). A 0.2 M mixture containing the corresponding carboxylic acid (1 eq), t-BuOH (5 eq), diphenylphosphoryl azide (DPPA, 1.2 eq), and 1,2-dimethoxyethane was heated at 100°C . for 16-20 h. The reaction mixture was allowed to reach room temperature, quenched with a saturated solution of NH_4Cl , and extracted with EtOAc. The organic phase was washed with a saturated solution of NaHCO_3 and then with water. The organic phase was dried over Na_2SO_4 and filtered, and the solvent removed under vacuum.

(169) The crude residue was resuspended in CH_2Cl_2 (at 0.2 M) and trifluoroacetic acid (TFA, 0.007 eq) was added. The reaction mixture was stirred at room temperature for 1-16 h, quenched by the addition of a saturated solution of NaHCO_3 , and then extracted with CH_2Cl_2 . The organic phase was dried over a phase separator and the solvent removed under vacuum. The crude residue was purified using ISCO flash chromatography.

(170) Some anilines required for the synthesis of compounds of the current invention can be

obtained by first reacting an appropriately substituted phenol with chlorosulfonic acid. The sulfonyl chlorides obtained in this way can be reacted with an appropriate amine in an appropriate solvent, such as ether, tetrahydrofuran, dichloromethane, dichloroethane, or the like, in the presence of a suitable base, such as triethylamine, diisopropylethylamine, potassium carbonate, or the like. The corresponding sulfonamides can then be converted to the corresponding aniline using many different conditions. One such set of conditions includes exposing the compound, in an appropriate solvent, such as ethyl acetate, methanol, isopropanol, or the like, to an atmosphere of hydrogen gas and in the presence of an appropriate catalyst, such as palladium on carbon, platinum on carbon, or the like. Alternatively, the nitroaromatic can be converted to the corresponding aniline by treatment with iron powder in an appropriate solvent, such as acetic acid. These procedures are shown in Scheme 12 and exemplified by General Procedures A, Y, and C or D. Such anilines can be reacted with appropriately substituted sulfonyl chlorides to synthesize compounds of the present invention.

(171) ##STR00027##

(172) General Procedure Y (Sulfonamide Coupling B). To a mixture containing the corresponding amine (1.5 eq) in THF (at [0.8 M]) was added Et.sub.3N (1.5 eq) was added. The reaction mixture was cooled to 0° C. in an ice/water bath. Then, the corresponding sulfonyl chloride (1 eq) was added and the reaction mixture allowed to come to rt and stir for 1-4 h at room temperature. Upon completion of the reaction, the mixture was cooled to 0° C. was quenched by the addition of 3 M aqueous HCl. The mixture was extracted using CH.sub.2Cl.sub.2. The organic phase was dried over phase separator and the solvent removed under reduced pressure. The crude material was purified using ISCO flash chromatography.

(173) Compounds of the present invention which are substituted with a methylsulfoxide or methylsulfone can be conveniently prepared by first reacting an appropriately substituted aromatic halide with sodium methanethiolate in an appropriate solvent, such as tetrahydrofuran or dioxane, in the presence of an appropriate palladium catalyst and a suitable ligand, such as Xantphos, at a temperature of 50-110° C. The aromatic sulfides produced in this way can be converted to the corresponding sulfones via the use of an oxidizing agent, such as Oxone or sodium periodate, in a suitable solvent, such as tetrahydrofuran, methanol, ethanol, water, or the like. Alternatively, the aromatic sulfides produced in this way can be converted to the corresponding sulfoxides via the use of an oxidizing agent, such as Oxone, sodium periodate, or meta-chloroperoxybenzoic acid, in a suitable solvent, such as tetrahydrofuran, methanol, ethanol, water, or the like, but with fewer equivalents of oxidizing agent and shorter reaction times compared to the synthesis of the sulfones. Aromatic compounds synthesized in this way can be reacted with nitric acid in the presence of sulfuric acid and in an appropriate solvent, such as dichloromethane, dichloroethane, or the like. Appropriately substituted nitro-substituted aromatic compounds synthesized in this way can be converted to the corresponding aniline using many different conditions. One such set of conditions includes exposing the compound, in an appropriate solvent, such as ethyl acetate, methanol, isopropanol, or the like, to an atmosphere of hydrogen gas and in the presence of an appropriate catalyst, such as palladium on carbon, platinum on carbon, or the like. Alternatively, the nitroaromatic can be converted to the corresponding aniline by treatment with iron powder in an appropriate solvent, such as acetic acid. These procedures are shown in Scheme 10 and exemplified by General Procedures Z, U or V, B, and C or D. Such anilines can be reacted with appropriately substituted sulfonyl chlorides to synthesize compounds of the present invention.

Then, THF (to [0.34 M]) and Et.sub.3N (1.25 eq) were added and the reaction mixture was heated at 76° C. for 18 h. Upon cooling, the mixture was filtered and the solvent was removed under vacuum. The crude was purified using ISCO Flash chromatography.

C. EXAMPLES

(176) All chemical reagents and reaction solvents were purchased from commercial suppliers and used as received. All microwave-assisted reactions were performed using a Biotage Initiator 2.0 microwave reactor. Hydrogenation reactions are performed using an atmospheric balloon, or using a Parr hydrogenation shaker apparatus where stated. Analytical thin-layer chromatography (TLC) was performed on Kieselgel 60 F254 glass plates precoated with a 0.25 mm thick silica gel. TLC plates were visualized with UV light and iodine.

(177) All compounds were obtained at 95% purity or higher, unless otherwise noted, as measured by analytical reversed-phase HPLC. Analytical HPLC was performed on an Agilent 1200 series system with UV detection at 214 and 254 nm, along with evaporative light-scattering detection (ELSD). Low-resolution mass spectra were obtained on an Agilent 6140 mass spectrometer with electrospray ionization (ESI). For LCMS characterization of the compounds in the present invention, one of the following methods were used: Method A: A Phenomenex Kinetex 2.6 μm XB-C18 100 Å LC column (50 Å~2.1 mm) was used with a 2 min gradient of 5-95% MeCN in H.sub.2O and 0.1% TFA. Normal phase flash silica gel-based column chromatography was performed using ready-to-connect cartridges from ISCO, on irregular silica gel, particle size 15-40 μm using a Teledyne ISCO Combiflash Rf system. Preparative reverse-phase HPLC was performed on a Gilson instrument equipped with a Phenomenex Kinetex C18 column, using varying concentrations of MeCN in H.sub.2O and 0.1% TFA, unless otherwise stated.

(178) Proton nuclear magnetic resonance (.sup.1H NMR) spectra were recorded at either 400 or 600 MHz on a Bruker spectrometer, as stated. For .sup.1H NMR spectra, chemical shifts are reported in parts per million (ppm) relative to residual nondeuterated solvent signals. Coupling constants are reported in hertz (Hz). 3. Pharmaceutical Compositions

(1168) The disclosed compounds may be incorporated into pharmaceutical compositions suitable for administration to a subject (such as a patient, which may be a human or non-human).

(1169) The pharmaceutical compositions may include a “therapeutically effective amount” or a “prophylactically effective amount” of the agent. A “therapeutically effective amount” refers to an amount effective, at dosages and for periods of time necessary, to achieve the desired therapeutic result. A therapeutically effective amount of the composition may be determined by a person skilled in the art and may vary according to factors such as the disease state, age, sex, and weight of the individual, and the ability of the composition to elicit a desired response in the individual. A therapeutically effective amount is also one in which any toxic or detrimental effects of a compound of the invention [e.g., a compound of formula (I) or (II)] are outweighed by the therapeutically beneficial effects. A “prophylactically effective amount” refers to an amount effective, at dosages and for periods of time necessary, to achieve the desired prophylactic result. Typically, since a prophylactic dose is used in subjects prior to or at an earlier stage of disease, the prophylactically effective amount will be less than the therapeutically effective amount.

(1170) For example, a therapeutically effective amount of a compound of formula (I) or (II), may be about 1 mg/kg to about 1000 mg/kg, about 5 mg/kg to about 950 mg/kg, about 10 mg/kg to about 900 mg/kg, about 15 mg/kg to about 850 mg/kg, about 20 mg/kg to about 800 mg/kg, about 25 mg/kg to about 750 mg/kg, about 30 mg/kg to about 700 mg/kg, about 35 mg/kg to about 650 mg/kg, about 40 mg/kg to about 600 mg/kg, about 45 mg/kg to about 550 mg/kg, about 50 mg/kg to about 500 mg/kg, about 55 mg/kg to about 450 mg/kg, about 60 mg/kg to about 400 mg/kg, about 65 mg/kg to about 350 mg/kg, about 70 mg/kg to about 300 mg/kg, about 75 mg/kg to about 250 mg/kg, about 80 mg/kg to about 200 mg/kg, about 85 mg/kg to about 150 mg/kg, and about 90 mg/kg to about 100 mg/kg.

(1171) The pharmaceutical compositions may include pharmaceutically acceptable carriers. 4. Methods of Treatment

(1208) The disclosed compounds and compositions may be used in methods for treatment of MYC-related cancers. The methods of treatment may comprise administering to a subject in need of such treatment a composition comprising a therapeutically effective amount of the compound of formula (I) or (II).

(1209) In one aspect, disclosed is a method of treating cancer, the method comprising administration of a therapeutically effective amount of a compound of formula (I) or (II), or a pharmaceutically acceptable salt thereof to a subject in need thereof.

(1210) In certain embodiments, the cancer being treated is associated with overexpression of MYC.

(1211) In certain embodiments, the cancer is at least one of leukemia, ovarian cancer, breast cancer, colorectal cancer, pancreatic cancer, gastric cancer, stomach cancer, lung cancer, cervical cancer, uterine cancer, cancers of the blood, and cancers of the lymphatic system.

(1212) In another aspect, disclosed is a method of disrupting the protein-protein interaction between WDR5 and MYC, the method comprising administration of a therapeutically effective amount of a compound of formula (I) or (II), or a pharmaceutically acceptable salt thereof to a subject in need thereof.

(1213) The compositions can be administered to a subject in need thereof to bind WDR5 and modulate MYC, to treat a variety of diverse cancers. The present disclosure is directed to methods for administering the composition to inhibit the protein-protein interaction between WDR5 its binding partners such chromatin, cognate transcription and other regulatory factors, including for example the histone methyltransferase MLL.

(1214) The compositions may be useful for treating certain cancers in humans and animals related to MYC overexpression. Treatment of such cancers may be effected by modulating MYC binding to WDR5 in a subject, by administering a compound or composition of the invention, either alone or in combination with another active agent as part of a therapeutic regimen to a subject in need thereof.

(1215) Disruption of the the interaction between WDR5 and its binding partners (such as MYC) may lead to treatment and reduction of cancer or tumor growth, and/or reduce metastasis of cancerous or tumor cells. Accordingly, the disclosed compositions may be used in methods that treat and/or prevent cancer or tumors in a subject administered the composition. The method can treat cancer or tumor-based growth and can be any type of cancer such as, but not limited to, leukemia (mixed-lineage leukemia), ovarian cancer, breast cancer, colorectal cancer, pancreatic cancer, gastric cancer, stomach cancer, lung cancer, cervical cancer, uterine cancer, cancers of the blood, and cancers of the lymphatic system.

(1216) In some embodiments, the administered composition to a subject in need thereof may mediate reduction, clearance or prevention of additional growth of tumor cells by disrupting the ability of MYC, another transcription factor, or chromatin to associate with WDR5, thereby reducing growth/proliferation of tumor cells, but does not have an effect on normal cells.

(1217) In some embodiments, the administered composition may increase tumor free survival, reduce tumor mass, slow tumor growth, increase tumor survival, or a combination thereof in the subject. The administered composition may reduce tumor volume in the subject in need thereof. The administered composition may increase tumor free survival in the subject after administration of the composition.

(1218) In some embodiments, the composition may be administered to clear or eliminate the cancer or tumor expressing the one or more oncogenes without damaging or causing illness or death in the subject administered the composition.

Biological Example 1. Fluorescence Polarization Anisotropy Assay

(1227) Compounds of the present invention were assessed for their ability to bind to WDr5 using a competition-based fluorescence polarization anisotropy assay, similar to the method previously described. (Thomas, Fesik, Tansey, et al, Molecular Cell 2015 (58): 440-452). Fluorescence polarization measurements were performed in 384-well plates (Greiner Bio One) using a Cytation 3 plate reader (BioTek). Fluorescein isothiocyanate (FITC)-labeled peptide probe (FITC-AHx-SEEEIDVVSF) was purchased from GenScript USA Inc and used without further purification. Fluorescein isothiocyanate (FITC)-labeled small molecule probes were synthesized using procedures analogous to the procedures described above. The assay buffer contained 200 mM phosphate, 300 mM NaCl, and 0.5 mM TCEP and 0.1% Chaps at pH 6.0. Compounds were serially

diluted in assay buffer at a top concentration sufficient to yield a 9-point dose-response curve. The change in fluorescence anisotropy was measured and used to calculate an IC₅₀ (inhibitor concentration at which 50% of bound probe is displaced) by fitting the inhibition data using a single-site binding model implemented in the XL Fit software (XLfit). This was converted into a binding dissociation constant (K_d value) according to the formula:

$$K_{d,i} = [I]_{50} / ([L]_{50} / K_{d,l} + [P]_0 / K_{d,l} + 1)$$

where [I]₅₀ is the concentration of the free inhibitor at 50% inhibition, [L]₅₀ is the concentration of the free labeled ligand at 50% inhibition, [P]₀ is the concentration of the free protein at 0% inhibition, and K_d represents the dissociation constant of the FITC labeled probe (Nikolovska-Coleska et al., 2004).

(1228) Data shown in the table below represents a K_d determined from this method for each Example, using either a fluorescently labeled small molecule probe analogous to Example J2 or Example HCH-25, or the peptide probe described above, in the assay.

Biological Example 2. Co-Immunoprecipitation Experiments

(1230) Some compounds of the present invention were also assessed for their ability to interrupt the binding between MYC and WDR5 in whole cells and/or cellular lysates.

(1231) To prepare the cells, procedures analogous to the following procedures were used. HEK293 cells stably expressing MYC2HA were made by retroviral transduction followed by selection in Hygromycin (50 $\mu\text{g/mL}$). The mixed population was then infected with pBabe-Puro expressing GFP or WDR5 with selection in puromycin (1 $\mu\text{g/mL}$). For retroviral transductions, HEK293T cells were transfected with the appropriate pBabe vector, the pCL10A packaging vector, and pMax-GFP to estimate transfection efficiency. Viral supernatant was collected and used to infect HEK293 class over three days. HEK293 cells were maintained in DMEM supplemented with 10% FBS.

Hygromycin B (50 $\mu\text{g/mL}$) and puromycin (100 ng/mL) were added to media to maintain plasmid expression. Both cell lines were tested and confirmed negative of mycoplasma using the VenorGem PCR test kit (Sigma Aldrich). After thawing from liquid nitrogen, cells were passaged at least twice before use in experiments, and passaged for a maximum of 25 times.

(1232) To perform the experiments, procedures analogous to the following procedures were used. HEK293 cells were harvested and lysates were prepared on ice in lysis buffer (50 mM Tris-HCl pH 8.0, 150 mM NaCl, 5 mM EDTA, 1% Triton X100 and supplemented with protease and phosphatase inhibitors). Equal amounts of protein lysate were subject to immunoprecipitation with M2 agarose overnight (for WDR5-c-MYC) or for 2 hours with magnetic M2 beads (for WDR5-RbBP5) at 4° C. Immune complexes were recovered, washed in lysis buffer, and resolved by SDS-PAGE. Immunoblotting was performed using the indicated primary antibodies (the following primary antibodies were used for this study: α -c-MYC (#5605), α -RbBP5 (#13171), α -WDR5 (#13105), α -FLAG (#8146) all purchased from Cell Signaling), incubated with labeled secondary antibodies and membranes were scanned using the Odyssey imager (LiCor).

(1233) The results of co-immunoprecipitation experiments for selected compounds of the invention are shown in FIG. 1, FIG. 2, and FIG. 3. FIG. 1 shows selected compounds tested at 50 μM . FIG. 2. Shows selected compounds tested at 30 μM . FIG. 3. Shows selected compounds tested at 50 μM .

(1234) It is understood that the foregoing detailed description and accompanying examples are merely illustrative and are not to be taken as limitations upon the scope of the invention, which is defined solely by the appended claims and their equivalents.

(1235) Various changes and modifications to the disclosed embodiments will be apparent to those skilled in the art. Such changes and modifications, including without limitation those relating to the chemical structures, substituents, derivatives, intermediates, syntheses, compositions, formulations, or methods of use of the invention, may be made without departing from the spirit and scope thereof.
