Background/Summary

TECHNICAL FIELD

[0001] The present disclosure belongs to the field of pharmaceuticals, and relates to a fused imidazole derivative, a preparation method therefor and pharmaceutical use thereof. In particular, the present disclosure relates to a fused imidazole derivative of general formula (IM), a preparation method therefor, a pharmaceutical composition comprising the derivative, and use of the derivative as a GLP-1 receptor agonist in the field of diabetes treatment.

BACKGROUND

[0002] Diabetes is a metabolic disease of multiple etiologies characterized by chronic hyperglycemia accompanied by disturbances in the metabolism of sugars, lipids and proteins due to a deficiency of insulin secretion or its action. Diabetes is a very ancient disease, and is caused by the absolute or relative deficiency of insulin in the human body, so that the concentration of glucose in blood is increased, and then a large amount of sugar is discharged from urine, accompanied by symptoms such as polydipsia, diuresis, polyphagia and emaciation.

[0003] Generally, there are two types of diabetes. Patients with type I diabetes, i.e., patients with insulin-dependent diabetes, produce little or no insulin by themselves. Insulin is a hormone used in the body to regulate glucose utilization. Patients with type II diabetes, i.e., patients with non-insulin-dependent diabetes, have the same or higher insulin level in their plasma as or than the non-diabetic population. However, such patients develop resistance to insulin which stimulates glucose and lipid metabolism in cells of major insulin-sensitive tissues, such as muscle, liver and adipose tissues. Even with elevated plasma insulin level, the patients' significant resistance to insulin cannot be overcome.

[0004] In addition to insulin resistance resulting from a reduction in the number of insulin receptors, a deficiency of insulin receptors can also lead to insulin resistance and this mechanism has not been fully understood. Insulin responsiveness (insulin resistance) results in failure of insulin to activate the uptake, oxidation and storage of glucose in muscle tissue, failure of effective inhibition of lipolysis in adipose tissue, and failure of effective inhibition of the production and secretion of glucose in the liver.

[0005] Glucagon-like peptide-1 (GLP-1) is an incretin hormone secreted from L-cells in the distal intestine.

[0006] GLP-1 plays a corresponding role by binding to its ubiquitous specific receptor. Organs in which GLP-1 receptor is now clearly present include islet cells, gastrointestinal, pulmonary, brain, kidney, hypothalamus and cardiovascular systems, and GLP-1 receptor may also be present in liver, adipose tissues and skeletal muscle. GLP-1 not only acts on β cells to promote insulin secretion,

but also acts on a cells to inhibit glucagon secretion. There is generally no significant difference in serum GLP-1 levels in patients with normal glucose tolerance, impaired glucose tolerance, and type II diabetes. However, there is a deficiency of the response of R cells to GLP-1 after eating, and under certain conditions, the response is significantly enhanced after continuous infusion of GLP-1. Since the duration of action of human GLP-1 is very short ($t_{1/2} < 1.5$ minutes via intravenous injection), human GLP-1 is not suitable for clinical treatment of diabetes.

[0007] Peptidic GLP-1 receptor agonists (e.g., liraglutide and exenatide) have effects on improving blood glucose level in type II diabetic patients by lowering fasting and postprandial glucose.

However, since the peptidic GLP-1 has poor oral bioavailability and is inconvenient to take, small molecule agonists of GLP-1 receptors with good oral bioavailability are highly desirable.

[0008] The small molecule agonists of GLP-1 receptors are disclosed in patent applications including WO2009111700A2, WO2010114824A1, WO2018109607A1, WO2019239319A1, WO2018056453A1, and the like.

Biological Evaluation

Test Example 1: Evaluation of Agonist Activity Against GLP-1 Receptor

I. Purpose

[0661] This experiment was intended to test the agonist activity of the compound molecules against the GLP-1 receptor and evaluate the in vitro activity of the molecules according to EC.sub.50. The experiment adopted a ONE-Glo™ Luciferase Assay System (Promega, E6110). Under the action of compound molecules, GLP-1R downstream signaling pathways were activated to cause elevated cAMP level. The combination of cAMP and CRE could start the transcription expression of CRE downstream luciferase genes, the luciferase could emit fluorescence when reacting with substrates thereof, and the activity of the compound for agonizing GLP-1 receptors was reflected by measuring fluorescence signals through a ONE-Glo™ reagent.

II. Method

[0662] Stably-expressed CHO-K1/CRE-luc/GLP-1 receptor cell strains (self-construction of GLP-1 receptor plasmid; CRE-luc plasmid Promega E8471) were constructed. CHO-K1/CRE-luc/GLP-1 receptor cells were digested, and resuspended after centrifugation. Single cell suspension was

uniformly mixed, and adjusted to a viable cell density of 2.5×10^5 cells/mL with a cell culture medium (DME/F-12+10% FBS), and the resulting solution was added to a 96-well cell culture plate at 90 μ L/well (Corning, #3903). The plate was incubated in an incubator for 16 h (37° C., 5% CO₂).

[0663] The compound was dissolved in DMSO to prepare a stock solution with an initial concentration of 20 mM. The starting concentration of the small molecule compound was 0.2 mM, and the compound underwent 3-fold serial dilution for a total of 10 concentration points, with DMSO at the 11^{sup}.th point. To another 96-well plate was added 95 µL of cell culture medium (DME/F-12+10% FBS), 5 µL of test samples with different concentrations were added to each well, followed by uniform mixing, and then 10 µL of test samples with different concentrations were added to each well, with two duplicate wells set for each sample. The plate was incubated in an incubator for 6 h (37° C., 5% CO₂). The 96-well cell culture plate was taken out, and 100 µL of ONE-Glo™ reagent was added to each well, followed by incubation at room temperature for 10 min. The plate was placed in a microplate reader (EnVision 2105, PE) for determination of chemiluminescence.

III. Data Analysis

[0664] Data were processed and analyzed using Microsoft Excel and Graphpad Prism 5. EC.sub.50 values of the compounds were obtained, and the results are shown in Table 1 below.

Test Example 2: Effect of Compounds of the Present Disclosure on hERG Potassium Ion Channel

I. Purpose

[0665] This example is intended to assess the blocking effect of the compounds of the present disclosure and positive compound 1 (see the compound of Example 7 on page 125 of WO2019239319A1) on hERG potassium currents in a stable cell strain transfected with an hERG potassium channel by a manual patch-clamp assay. The structure of positive compound 1 is shown below:

##STR00197##

II. Method

1. Cell Culture

[0666] The cells used in this experiment were from a CHO cell line (provided by Sophion Bioscience, Denmark) transfected with hERG cDNA and stably expressing hERG channel at cell passage number of P5. Cells were cultured in a medium containing the following components (all from Invitrogen): Ham's F12 medium, 10% (v/v) inactivated fetal bovine serum, 100 g/mL hygromycin B, and 100 g/mL geneticin.

[0667] CHO hERG cells were grown in a culture dish containing the above culture medium and cultured in an incubator at 37° C. with 5% CO₂. 24-48 h before the electrophysiological experiment, CHO hERG cells were transferred to round slides placed in the culture dish and grown in the same culture medium and culture conditions as above. The density of CHO hERG cells on each round slide was required to achieve the requirement that most cells were independent and individual.

3. Electrophysiological Recording System

[0668] In this experiment, a manual patch-clamp system (HEKA EPC-10 signal amplifier and digital conversion system, purchased from HEKA Electronics, Germany) was used for whole cell current recording. Round slides with CHO hERG cells grown on the surface were placed in an electrophysiological recording chamber under an inverted microscope. The chamber was continuously perfused with extracellular fluid (approximately 1 mL/min). The experimental procedures were performed by conventional whole-cell patch-clamp current recording technology. Unless otherwise stated, the experiment was performed at room temperature (−25° C.). The cells were clamped at a voltage of −80 mV. The cell clamp voltage was depolarized to +20 mV to activate the hERG potassium channel, and then clamped to −50 mV 5 s later to eliminate inactivation and generate tail currents. The tail current peak was used as a value for the numeral value of the hERG current. After the hERG potassium currents recorded in the above step were stable under the continuous extracellular fluid perfusion in the recording chamber, the drug to be tested could be added for perfusion until the inhibitory effect of the drug on the hERG current reached a stable state. Generally, the last superposition of 3 consecutive current recording lines is used as a criterion for determining whether a stable state is reached. After reaching a stable state, the chamber was flushed by perfusion with extracellular fluid until the hERG currents returned to the level before dosing. One or more drugs, or multiple concentrations of the same drug, can be tested on one cell, but extracellular fluid flushes are required between different drugs. Cisapride (purchased from Sigma) was used as a positive control in the experiment to ensure that the cells used were of normal quality.

4. Procedures

[0669] To obtain IC.sub.50 of the compounds, the following concentrations (30 μM, 10 μM, 3 μM, 1 μM, 0.3 μM and 0.1 μM) were selected for testing. Prior to the test, the compound was formulated into a 10 mM DMSO stock solution with DMSO (Sigma), which was diluted in a gradient to obtain stock solutions at 3 mM, 1 mM, 0.3 mM and 0.1 mM. The stock solutions were then diluted with extracellular fluid to the final M test concentrations. The final concentration of DMSO was 0.1% in each concentration of compound solution except for the 30 M compound test solution in which the final concentration of DMSO was about 0.3%. The test concentration of the control cisapride was 0.1 μM. All compound solutions were routinely sonicated and shaken for 5 to 10 min to ensure complete dissolution of the compounds.

[0670] The experimental data were analyzed by data analysis software supplied by HEKA Patchmaster (V2×73.2), Microsoft Excel, and Graphpad Prism 5.0.
