Background/Summary

CROSS REFERENCE TO RELATED APPLICATIONS [0001] The present application claims the benefit of U.S. Provisional patent application 63/084,699 filed Sep. 29, 2021, the entire contents of which is incorporated by reference herein.

TECHNICAL FIELD

[0003] This invention relates to inhibitors of PF4 tetramerization useful in treating, for example, heparin induced thrombocytopenia (HIT) or heparin induced thrombocytopenia and thrombosis (HITT).

BACKGROUND

[0004] Heparin-induced thrombocytopenia and thrombosis (HITT) is a serious complication of heparin therapy. Heparin is a naturally-occurring anticoagulant that prevents the formation of clots and extension of existing clots within the vasculature. Major medical applications of heparin include dialysis, cardiac catheterization, and cardiopulmonary bypass surgery. However, heparin therapy may lead to a serious complication known as heparin induced thrombocytopenia (HIT). HIT is caused by an immunological reaction that targets platelets leading to a low platelet count (thrombocytopenia). HIT increases the risk of blood clots forming within blood vessels and blocking the flow of blood (thrombosis), referred to as HITT when thrombosis occurs. HITT develops in approximately 1-3% of patients treated with heparin for 5-10 days. Affected individuals have a 20-50% risk of developing new thromboembolic events, a mortality rate of about 20%, and an additional ~10% of patients require amputations or suffer other major morbidity. The rate of occurrence of HITT is about 10-20 cases/yr/hospital, and the patients with this condition are not

adequately treated by existing therapies.

[0005] Despite the introduction of low molecular weight heparins (LMWH) and the synthetic pentasaccharide fondaparinux, HITT continues to be a significant medical problem. This is likely due to the fact that heparin remains the anticoagulant of choice for many patients (such as patients undergoing cardiopulmonary bypass or percutaneous coronary intervention, at high risk for bleeding, or with renal failure). HITT occurs even after treatment with LMWHs, although at a reduced rate compared to unfractionated heparin in some patients. As a large number of hospitalized patients are exposed to heparin, HITT is a major treatment-induced cause of morbidity and mortality in this patient population.

SUMMARY

[0006] The present application provides compounds that inhibit platelet activation by directly inhibiting tetramerization of platelet factor 4 (PF4), and may be useful in treating diseases and conditions in which increased blood clotting is indicated. Suitable examples of such diseases include HIT and HITT. The compounds of the present application have high potency at a μM level, little or no activity against other chemokines, excellent ADMET properties including microsome stability and little or no cytochrome P450 inhibition, little or no cytotoxicity, little or no hERG inhibition, good aqueous solubility and PK parameters suitable for intravenous (IV) administration, such as moderate-long half-life, and low clearance and volume of distribution. DETAILED DESCRIPTION

[0057] The clinical manifestations of HITT are caused by antibodies that recognize a complex composed of heparin and tetramers of platelet factor 4 (PF4). PF4 is a 70 amino acid, lysine-rich 7.8 kDa platelet-specific protein that belongs to the CXC (or beta) chemokine subfamily. PF4 is synthesized by megakaryocytes and comprises 2-3% of the total released protein in mature platelets. PF4 exists as a tetramer in the α-granules of platelets and is secreted in high concentrations when platelets are activated. PF4 tetramers bind avidly to glycosaminoglycans (GAGs). The interaction of PF4 with GAGs, including heparin, contributes to the pathogenesis of HITT with the formation of ultra large complexes of PF4 tetramers and heparin (ULCs) representing the major antigen recognized by pathogenic HITT antibodies. A transgenic mouse model of HITT demonstrates that heparin, PF4 (forming ULC), anti-heparin/PF4 antibody, and the platelet receptor FcγRIIa are necessary and sufficient to recapitulate the salient features of HITT in vivo. Treatment of patients with heparin is thought to favor the formation of the ULCs, placing these patients at risk for HITT.

[0058] A simplified mechanism of HITT pathophysiology is shown in FIG. 2, and demonstrates the feed-forward nature of this disorder. Specifically, antibody recognition of ULC leads to platelet activation, releasing more PF4, which can form additional ULC to be recognized by antibody. The compounds of the present application inhibit cellular activation by limiting the ULC formation. Referring to FIG. 2, in step (1) PF4 released from activated platelets as a tetramer forms a complex (ULC) with heparin which has been administered to a patient as an anticoagulant; in step (2) pathogenic antibodies bind to the complex of heparin and PF4 tetramer; in step (3) an antibody-decorated heparin-PF4 complex binds to a platelet via its FcγRIIa receptor; and in step (4) crosslinking of FcγRIIa leads to platelet activation and release of additional PF4, which can bind to heparin and feed the pathogenic cycle.

[0059] No specific treatments for heparin-induced thrombosis currently exist. For example, current treatment for HITT relies on removal of all heparin exposure from patients with suspected HITT and administration of a non-heparin alternative anticoagulant, typically a direct thrombin inhibitor, which may carry a significant risk of bleeding. Hence, despite discontinued heparin, the patients remain at significant risk for thrombosis and death.

[0060] Also disclosed herein are methods of treating thrombosis induced by a vaccine. Vaccine-induced immune thrombotic thrombocytopenia (VITT) is induced in otherwise healthy individuals after an adenovirus-based vaccine and is characterized by development of thrombocytopenia and thrombosis in atypical locations (including, but not limited to, the cerebral and/or splanchnic veins) within weeks of receiving a vaccination. VITT has most recently been identified in subject receiving adenovirus-based SARS-CoV-2 vaccines, which involves, in part, antibodies directed toward PF4 and/or PF4-heparin complexes.

[0061] Accordingly, the present application provides compounds that directly target and intervene in the pathophysiology of thrombosis, and limit and/or prevent the complications of this condition

and related diseases. Exemplary embodiments of the compounds, and methods of making and using these compositions, are described below.

Definitions

[0062] The term “PF4” as used herein refers to platelet factor 4 which is a 70 amino acid, lysine-rich, 7.8 kDa platelet-specific protein that belongs to the CXC (or beta) chemokine subfamily, in which the first two of the four conserved cysteine residues are separated by one amino acid residue. In some embodiments, PF4 is naturally occurring, i.e., wild-type. In other embodiments, PF4 may be synthesized by recombinant or chemical methods. The term PF4 also refers to mutations thereof in which one or more of the amino acids is replaced with a different amino acid. Examples of PF4 mutations are described in International Patent Publication No. WO 02/006300 and the inventors' prior publication WO2013/142328, which is incorporated herein by reference.

[0063] As used herein, the term “compound” is meant to include all stereoisomers, geometric isomers, tautomers, and isotopes of the structures named or depicted. Compounds herein identified by name or structure as one particular tautomeric form are intended to include other tautomeric forms unless otherwise specified.

[0064] As used herein, the term “tautomer” refers to compounds which are capable of existing in a state of equilibrium between two isomeric forms. Such compounds may differ in the bond connecting two atoms or groups and the position of these atoms or groups in the compound. Suitable examples of an equilibrium between the tautomeric forms are depicted in FIGS. 7A and 7B.

[0065] Referring to FIG. 7A, an indane-1,3-dione moiety having an R(C=O)— substituent in the 2-position may exist as an equilibrium between forms A, B, C, D and E. In this example, the R— group may correspond to C.sub.1-6 alkoxy, C.sub.1-6 alkyl or an NH(R.sup.a1) fragment, as in any one of the substituents R.sup.1-R.sup.4 in a compound of Formula (I) described herein. Based on the analysis of literature and NMR data presented herein, a compound containing an R(C=O)— substituent as depicted in FIG. 7A most likely exists in solution as an equilibrium between forms E and D. See, e.g., Liepinš, E. et al. *Magnetic Resonance in Chemistry* 1989, 27:907; Song, J. et al. *Organic Letters* 2007, 9, 4307; and Paul, B. K.; Guchhait, N. *Computational and Theoretical Chemistry* 2013, 1012, 2. Referring to FIG. 7B, an indane-1,3-dione moiety that is unsubstituted in the 2-position may exist as an equilibrium between forms F, G and H. This is the case of a compound of Formula (I) described herein when either R.sup.1 and R.sup.2 are both H, or R.sup.3 and R.sup.4 are both H, or R.sup.1—R.sup.4 are all H. Based on the analysis of NMR data, form F is favored in solution of such a compound.

[0066] As used herein, the term “isomer” refers to structural, geometric and stereo isomers. As the compound of the present application may have one or more chiral centers, it is capable of existing in enantiomeric forms.

[0067] As used herein, the phrase “optionally substituted” means unsubstituted or substituted. As used herein, the term “substituted” means that a hydrogen atom is removed and replaced by a substituent. It is to be understood that substitution at a given atom is limited by valency.

Methods of Use

[0385] Disruption of the functionally-active PF4 tetrameric state to form functionally-inactive monomers and dimers also inhibits PF4 function. To form a ULC, PF4 must be in the tetrameric state. As schematically shown in FIG. 1, inhibition of formation of a PF4 tetramer (FIG. 1B) consequently inhibits the formation of the ULC with heparin.

[0386] Although PF4 crystallizes as a tetramer, in solution it exists in a dynamic equilibrium between monomeric, dimeric and tetrameric forms (see scheme in FIG. 1). As such, the relative abundance of the oligomeric form of PF4 can be influenced by shifting this equilibrium. Given that the salt bridges between Glu28 and Lys50 are predicted to stabilize the tetrameric form of PF4, Lys50 was mutated to glutamic acid in an attempt to disrupt tetramer formation. PF4 with this mutation (K50E) readily forms dimers, but not tetramers. Importantly, ULCs are not formed when heparin is incubated with K50E mutated PF4. In accordance with this observation, PF4 antagonists of the present disclosure (which are thought to bind near these residues) inhibit both tetramerization and ULC formation.

[0387] In some embodiments, the compounds described herein may be docked and scored on their ability to bind to the dimer interface pocket lined by monomer lysines and glutamine residues in the protein structure of PF4 (see, e.g., FIG. 3).

[0388] In some embodiments, the compound of Formula (I) prevent formation of and/or disrupt the PF4 tetramer. The prevention and/or disruption may occur in vitro, ex vivo or in vivo. For example, the prevention of disruption may occur in a subject (i.e., after administering the compound to the subject), e.g., in need thereof.

[0389] In some embodiments, the compound of Formula (I) may prevent formation and/or disrupt complexes formed between glycosaminoglycan (GAG) or other polyanion and a PF4 tetramer. In some embodiments, pathogenic complexes of GAG and PF4 are very large and are referred to as ultralarge complexes (ULC). GAG (e.g., heparin):PF4 complexes smaller than 600 kDa are typically referred to as small complexes (SC). In some embodiments, ULCs are 600 kDa or larger. In other embodiments, ULCs are 670 kDa or larger.

[0390] GAGs are long unbranched polysaccharides having a repeating disaccharide unit (a hexose

(six-carbon sugar) or a hexuronic acid, linked to a hexosamine (six-carbon sugar containing nitrogen)). In some embodiments, the GAG is selected from among wild-type GAGs or synthetically produced GAGs. In some embodiments, the GAG is heparin, hyaluronan, hyaluronic acid, dermatan sulfate, keratan sulfate, or a chondroitin, or a salt thereof. In some embodiments, the GAG is heparin. In a further embodiment, the GAG is heparan sulfate.

[0391] PF4:heparin ULCs are more pathogenic than heparin:PF4 SCs. Heparin:PF4 ULCs are better recognized by HIT antibodies and lead to more platelet activation in the presence of these antibodies. Disruption of ULC represents a valid therapeutic target in the treatment of a disease mediated by the ULC, such as the HIT.

[0392] In some embodiments, the compounds described herein bind to PF4 monomers, PF4 trimers, PF4 dimers, and/or PF4 tetramers and inhibit the formation of the PF4 tetramers and/or inhibit a ULC formed with the PF4 tetramers. In some embodiments, the present compounds also disrupt a salt bridge in a PF4 tetramer and thereby disrupt or inhibit formation of the PF4 tetramer. In some embodiments, the compound binds to a specific site (e.g., specific amino acid) at the PF4 tetramer, trimer, dimer or monomer. In some embodiments, the compounds are capable of antagonizing an electrostatic attraction between the PF4 monomers, dimers, and trimers in the PF4 tetramer, and therefore successfully disrupt the salt bridge of the tetramer. For example, a functional group of the present compound of Formula (I) binds stronger to the PF4 monomer, dimer, or trimer, than they bind to one other.

[0393] The salt bridge between oligomers in the PF4 tetramer is formed via electrostatic interactions of a negatively charged amino acid, such as glutamic acid, of a first PF4 monomer or PF4 dimer, and a positively charged amino acid, such as lysine, of a second PF4 monomer or PF4 dimer. This salt bridge is typically formed by interaction of at least one Glu or at least one Lys on a first PF4 monomer or PF4 dimer, and at least one Lys or at least one Glu on a second PF4 monomer or PF4 dimer. In some embodiments, the salt bridge is formed via at least electrostatic interactions between Lys50 in a first PF4 monomer Glu28 in a second PF4 monomer. In other embodiments, the salt bridge is formed an electrostatic interaction between Glu128 or Lys350 of a first PF4 monomer or dimer, and Glu328 or Lys150 of a second PF4 monomer or dimer. In other embodiments, the salt bridge is formed via an electrostatic interactions between Glu228 or Lys450 of a first PF4 monomer or dimer and Glu428 or Lys250 of a second PF4 monomer or dimer. In some embodiments, the salt bridge is formed on a PF4 dimer-dimer interface. That is, the compound of the present disclosure disrupts the salt bridge on the PF4 dimer-dimer interface.

[0394] Typically, a PF4:heparin ULC is antigen that promotes production of an antibody that is specific to the complex. The antibody recognizes the complex composed of heparin and the PF4 tetramer, and forms a pathogenic ULC-antibody complex. By inhibiting formation and/or disruption PF4 tetramer, the compounds described herein inhibit binding of the pathogenic ULC-antibody complex to a FcγRIIa receptor on a surface of a platelet. This leads to inhibition of platelet activation, and results in decreased production of PF4 by the platelet. When the platelet is contacted with the compound in vitro, ex vivo, or in vivo (e.g., by administering the compound to the subject), the inhibition of binding of ULC-antibody complex to a FcγRIIa also leads to inhibition of platelet aggregation, increased high density lipoproteins, modulated (e.g., reduced) blood clotting or hemostasis, and corrected platelet imbalance in the subject (e.g., in need thereof). In some embodiments, the platelet imbalance results from heparin administration to the subject.

[0395] In one general aspect, the present application provides a method for diagnostic use or for use in determination of a dosage, or for pharmaceutical evaluation of a composition containing a compound of Formula (I) as described herein. Such methods include measuring a first level of PF4 tetramer in a first biological sample obtained from a subject and administering a first effective amount of the compound of Formula (I) that is required to decrease the first PF4 tetramer level. In other embodiments, methods for disrupting PF4 tetramers are provided and include measuring a first level of PF4 tetramer in a first biological sample obtained from a subject, administering a first

effective amount of the compound of Formula (I) required to decrease the first PF4 tetramer level, and optionally administering a medication which disrupts PF4 tetramers. The medication which disrupts PF4 tetramers may be administered prior to, concurrent with, or subsequent to the PF4 antagonists discussed herein.

[0396] In other embodiments, methods for disrupting PF4 tetramers are provided and include measuring a first level of PF4 tetramer in a first biological sample obtained from a subject, administering a first effective amount of the compound of Formula (I) required to decrease the first PF4 tetramer level, measuring a second level of PF4 tetramer in a second biological sample obtained from the subject, and administering a second effective amount of the compound of Formula (I) required to decrease the second PF4 tetramer level. Multiple samples can be obtained from the subject at any interval required, for example, to prevent or treat the medical condition.

[0397] In a further embodiment, methods for disrupting ULCs containing PF4 tetramers and heparin are provided. These methods include measuring a first level of ULCs in a first biological sample obtained from a subject and administering a first effective amount of the compound of Formula (I) required to decrease the first ULC tetramer level.

[0398] In yet other embodiments, methods for disrupting ULCs containing PF4 tetramers and heparin include measuring a first level of ULCs in a first biological sample obtained from a subject, administering a first effective amount of the compound of Formula (I) required to decrease the first ULC level, measuring a second level of ULCs in a second biological sample obtained from the subject, and administering a second effective amount of the compound of Formula (I) required to decrease the second ULC level.

[0399] In still a further embodiment, methods for preventing the formation of PF4 tetramers include measuring a first level of PF4 tetramer in a first biological sample obtained from a subject, administering a first effective amount of the compound of Formula (I) required to prevent formation of the PF4 tetramer, measuring a second level of PF4 tetramer in a second biological sample obtained from the subject, and administering a second effective amount of the compound of Formula (I) required to prevent formation of PF4 tetramer.

[0400] Also provided are methods for using the antagonistic compounds described herein for determining a subject's sensitivity to side effects or secondary medical conditions related to heparin administration. Further provided are methods for determining the likelihood of a subject to acquire a medical condition related to the formation of PF4 tetramers or ULCs containing PF4 tetramers and heparin. In some embodiments, these screening methods are useful in monitoring e.g., cancer patients. In other embodiments, these screening methods are useful in determining the likelihood of cancer patients being administered heparin in developing HIT or HITT. According to this method, biological samples are obtained from subjects and the level of PF4 tetramer and/or PF4 tetramer:GAG (heparin) ULC measured. The screening may be conducted using techniques commonly known and used in the art. Comparison of the levels of PF4 tetramer and/or PF4 tetramer:heparin ULC to a control level and/or negative control provides evidence that the patient may be treated using one or more of the antagonistic compounds described herein. In some embodiments, if the subject's PF4 tetramer and/or PF4 tetramer:heparin ULC level is higher than the PF4 tetramer and/or PF4 tetramer:heparin ULC level of a healthy subject, then antagonistic compound administration may be contemplated.

[0401] In some embodiments, the present application provides a method of treating a disease or condition characterized by PF4 tetramerization (e.g., a disease or medical condition related directly or indirectly to the formation of PF4 tetramers). The disease or medical condition may also be caused by the formation of PF4 tetramers. In some embodiments, the subject or patient has elevated levels of PF4 tetramer. In yet a further embodiment, the subject or patient has elevated levels of PF4 tetramer:GAG ULCs.

[0402] Suitable examples of a disease or condition include, but are not limited to, heparin-induced thrombocytopenia (HIT), heparin-induced thrombocytopenia and thrombosis (HIT), thrombotic

complication of HIT, antiphospholipid syndrome or atherosclerotic vascular disease, platelet imbalance or insufficiency, antiphospholipid syndrome, inflammation or inflammatory disease, vaccine-induced immune thrombotic thrombocytopenia (VITT), or clotting or hemostasis disorders.

[0403] In some embodiment, the disease or medical condition is heparin-induced thrombocytopenia (HIT). HIT results from the development of thrombocytopenia (low platelet count), for example, due to the administration of an anticoagulant (e.g., heparin or warfarin). In other embodiments, the disease or medical condition is heparin-induced thrombocytopenia and/or with thrombosis (HITT). HITT results when HIT precedes thrombosis (abnormal antibodies and abnormal blood clots form inside a blood vessel). In some embodiments, the thrombosis is characterized by lower than normal thrombin-antithrombin complex (TAT) level.

[0404] In other embodiments, the disease or medical condition is vaccine-induced immune thrombotic thrombocytopenia (VITT) also known as thrombosis with thrombocytopenia syndrome. In some embodiments, the VITT is caused by an adenovirus-based vaccine. In some embodiments, the vaccine is a adenovirus-based SARS-CoV-2 vaccine.

[0405] Treatment of atherosclerotic vascular disease typically involves anti-platelet therapy (e.g., aspirin and Plavix® that is not tolerated in all patients). For the treatment of thrombocytopenia, TPO analogs and mimetics (MPL agonists which activate MPL—the TPO receptor) may be used, but these drugs have significant side effects and compliance issues. Finally, some lipid lowering therapies are able to increase HDL, but the ability of available drugs to do so is limited. In other embodiments, the disease that may be successfully treated by the compound of Formula (I) is antiphospholipid syndrome.

[0406] In a further embodiment, atherosclerosis resulting from the formation of a PF4 tetramer may be treated using a compound of Formula (I) described herein. In still other embodiments, the disease or medical condition is a platelet imbalance. The treatment method thereby includes correcting this platelet imbalance or preventing a platelet imbalance. In one example, platelet levels are increased by stimulating platelet production. In another example, a decrease in platelet production is prevented. In a further example, the platelet imbalance (e.g., low levels of platelets) results from the formation of a PF4 tetramer. In yet another example, the platelet imbalance, i.e., low levels of platelets, results from heparin administration to a subject.

[0407] The compounds of Formula (I) discussed herein may also be an alternative therapy utilized to treat diseases related to thrombopoietin (TPO). The compounds may also be contemplated for use in preventing or treating inflammation which results from the formation of PF4 tetramers. The inflammation may be caused by any number of factors. In some embodiments, the inflammation is acute or chronic. In other embodiments, the inflammation is localized or systemic. The inflammation may be the result of a variety of factors and/or conditions. The compounds of Formula (I) may also be useful in therapies for subjects having atherosclerotic vascular disease in which the patient is intolerant to the conventional treatments (e.g., statins). In some embodiments, an inflammatory disease is chronic inflammatory demyelinating polyneuropathy, inflammatory myopathy, inflammatory bowel diseases (IBDs), Crohn disease (CD), ulcerative colitis (UC), chronic inflammatory condition with polygenic susceptibility, inflammation of the uvea (e.g., anterior uveitis, e.g., iridocyclitis or iritis; intermediate uveitis (also known as pars planitis); posterior uveitis; or chorioretinitis, e.g., pan-uveitis).

[0408] The compounds described herein may further be useful for modulating clotting or hemostasis. In one example, the compounds may be useful in patients that are intolerant to conventional therapies. Alternatively, the compounds of the present application may be synergistic with the conventional therapies.

[0409] The compounds of Formula (I) are also useful in increasing high density lipoproteins (HDL) in a subject. Alternatively, the PF4 antagonists of the present application are useful in preventing a decrease of HDLs.

See, for example, Remington: The Science and Practice of Pharmacy, Lippincott Williams & Wilkins, Baltimore, MD (20th ed. 2000). Such preparative methods include the step of bringing into association with the molecule to be administered ingredients such as the carrier that constitutes one or more accessory ingredients. In general, the compositions are prepared by uniformly and intimately bringing into association the active ingredients with liquid carriers, liposomes or finely divided solid carriers, or both, and then, if necessary, shaping the product.

[0425] In some embodiments, any one of the compounds and therapeutic agents disclosed herein

are administered orally. Compositions of the present application suitable for oral administration may be presented as discrete units such as capsules, sachets, granules or tablets each containing a predetermined amount (e.g., effective amount) of the active ingredient; a powder or granules; a solution or a suspension in an aqueous liquid or a non-aqueous liquid; an oil-in-water liquid emulsion; a water-in-oil liquid emulsion; packed in liposomes; or as a bolus, etc. Soft gelatin capsules can be useful for containing such suspensions, which may beneficially increase the rate of compound absorption. In the case of tablets for oral use, carriers that are commonly used include lactose, sucrose, glucose, mannitol, and silicic acid and starches. Other acceptable excipients may include: a) fillers or extenders such as starches, lactose, sucrose, glucose, mannitol, and silicic acid, b) binders such as, for example, carboxymethylcellulose, alginates, gelatin, polyvinylpyrrolidinone, sucrose, and acacia, c) humectants such as glycerol, d) disintegrating agents such as agar-agar, calcium carbonate, potato or tapioca starch, alginic acid, certain silicates, and sodium carbonate, e) solution retarding agents such as paraffin, f) absorption accelerators such as quaternary ammonium compounds, g) wetting agents such as, for example, cetyl alcohol and glycerol monostearate, h) absorbents such as kaolin and bentonite clay, and i) lubricants such as talc, calcium stearate, magnesium stearate, solid polyethylene glycols, sodium lauryl sulfate, and mixtures thereof. The formulations may be presented in unit-dose or multi-dose containers, for example, sealed ampules and vials, and may be stored in a freeze dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example water for injections, saline (e.g., 0.9% saline solution) or 5% dextrose solution, immediately prior to use. Extemporaneous injection solutions and suspensions may be prepared from sterile powders, granules and tablets. The injection solutions may be in the form, for example, of a sterile injectable aqueous or oleaginous suspension. This suspension may be formulated according to techniques known in the art using suitable dispersing or wetting agents and suspending agents. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose, any bland fixed oil may be employed including synthetic mono- or diglycerides. Fatty acids, such as oleic acid and its glyceride derivatives are useful in the preparation of injectables, as are natural pharmaceutically-acceptable oils, such as olive oil or castor oil, especially in their polyoxyethylated versions. These oil solutions or suspensions may also contain a long-chain alcohol diluent or dispersant.

[0427] The pharmaceutical compositions of the present application may be administered in the form of suppositories for rectal administration. After 5 min the dry ice acetone bath was removed and contents stirred for 18 hours. Once LCMS confirmed the reaction to be complete the reaction vessel was placed in an ice water bath. Then 2N HCl 15.0 ml was added and a solid fell from solution. Stirring was maintained for a 30 min and then filtered. The solid was washed with 25 ml of 2N HCl and 25 ml of Et.sub.2O and then air dried overnight. The solid was then added to an excess of 1 N NaOH (basic solution according to pH) and 10 ml of CHCl.sub.3 and sonicated for 10 min. The resulting suspension was filtered and air dried overnight. To this was added NBS (2.97 g, 16.68 mmol), which briefly turned the mixture a deep orange color. The mixture was allowed to stir at ambient temperature and followed by LCMS. As the reaction progressed it became a very thick orange slurry. Once complete, the reaction was diluted with 50 ml of DCE, then filtered to remove the SiO.sub.2. After filtration, charge 50 ml of 10 wt % sodium metabisulfite solution and transfer to a separatory funnel. The layers were split and the lower organic was dried with sodium sulfite, filtered and concentrated to a foam. The foam was dissolved, concentrated on silica and then purified by column chromatography using EtOAc/hexanes to provide the product as a fine white solid (1.25 g, 35% yield). The mixture was stirred at -70°C . for 5 min and allowed to warm to rt. 2,3-Dimethyl 6-chloropyridine-2,3-dicarboxylate (CAS Regno: 32383-03-2, 220 mg, 0.95 mmol) was added, followed by dry DMF (2 ml). The mixture was stirred at rt for 1 day, diluted with EtOAc (90 ml), washed with 5% aq HCl (20 ml), 1 M aq NaOH (20 ml) and brine (20 ml), and dried over Na.sub.2SO.sub.4. Removal of the solvent left an oil (330 mg), which was chromatographed on a 40 g silica cartridge, eluted with a 0-50% EtOAc in hexanes gradient to give 2,3-dimethyl 6-[3,4-bis(methoxycarbonyl)phenoxy]pyridine-2,3-dicarboxylate (126 mg, 33%) as an oil. .sup.1H NMR (300 MHz, CHLOROFORM-d) δ 8.17-8.38 (m, 1H), 7.79 (d, J=8.35 Hz, 1H), 7.46 (d, J=2.64 Hz, 1H), 7.29-7.37 (m, 1H), 7.05 (d, J=8.35 Hz, 1H), 3.90 (s, 6H), 3.89 (s, 6H). LC-MS ESI.sup.+ t.sub.R 4.43 min, m/z 426, 404, 372.

[0748] Step 2: A solution of 2,3-dimethyl 6-[3,4-bis(methoxycarbonyl)phenoxy]pyridine-2,3-dicarboxylate (126 mg, 0.31 mmol) in MeOH (9 ml) and 1 M aq NaOH (3 ml, 3.0 mmol) was stirred at rt for 3 day. Additional MeOH (3 ml) and 1 M aq NaOH (1.5 ml, 1.5 mmol) were added and stirring at rt was continued for 4 days. The mixture was concentrated under reduced pressure. The solid residue was taken up in 5% aq HCl (5 ml) and MeCN (5 ml) and concentrated to dryness under reduced pressure to leave crude 6-(3,4-dicarboxyphenoxy)pyridine-2,3-dicarboxylic acid which was used directly in the next step. LC-MS ESI.sup.+ t.sub.R 2.63 min, m/z 330, 312.

[0749] Step 3: Crude 6-(3,4-dicarboxyphenoxy)pyridine-2,3-dicarboxylic acid (50.31 mmol) from the previous step was heated at reflux with toluene (6 ml) and SOCl.sub.2 (2.7 ml) for 18 hr. The mixture was concentrated, chasing with CH.sub.2Cl.sub.2, to give crude 2-[(1,3-dioxo-1,3-dihydro-2-benzofuran-5-yl)oxy]-5H,7H-furo[3,4-b]pyridine-5,7-dione which was used directly in the next step.

[0750] Step 4: To a stirred mixture of crude 2-[(1,3-dioxo-1,3-dihydro-2-benzofuran-5-yl)oxy]-5H,7H-furo[3,4-b]pyridine-5,7-dione (50.31 mmol) from the previous step, pentane-2,4-dione (80 mg, 0.79 mmol) and acetic anhydride (1.4 ml, 14.8 mmol) was added Et.sub.3N (0.4 ml, 2.8 mmol). The mixture was stirred at rt for 1 hr and 5% aq HCl (5 ml) was added. The mixture was stirred at rt for 2 hr, diluted with water (5 ml) and extracted with CH.sub.2Cl.sub.2 (45 ml). The organic layer was washed with brine (5 ml), dried over Na.sub.2SO.sub.4 and concentrated to leave an oil (200 mg). Chromatography on a silica cartridge, eluted with a 0-100% EtOAc in hexanes gradient, gave two fractions: 6,6-diacetyl-2-[(2,2-diacetyl-1,3-dioxo-2,3-dihydro-1H-inden-5-yl)oxy]-5H,6H,7H-cyclopenta[b]pyridine-5,7-dione (32 mg, eluted first) and 6,6-diacetyl-2-[(2-acetyl-1,3-dioxo-2,3-dihydro-1H-inden-5-yl)oxy]-5H,6H,7H-cyclopenta[b]pyridine-5,7-dione (60 mg, eluted second). Each fraction was separately taken up in acetic anhydride (1.5 ml) and treated with Et.sub.3N (0.15 ml). The mixtures were each stirred overnight at rt, diluted with water (5 ml) and extracted with CH.sub.2Cl.sub.2 (2 $\times$ 35 ml). The combined CH.sub.2Cl.sub.2 extracts from each reaction were washed with brine (10 ml), dried over Na.sub.2SO.sub.4 and concentrated to give two crude products (60 mg from each) which both contained desired product. Prep HPLC gave the title compound (7.6 mg, 6% from Step 1 product) as an ochre yellow solid. .sup.1H NMR (300 MHz, DMSO-d6) δ 7.92-8.07 (m, 1H), 7.72 (br d, J=8.35 Hz, 1H), 7.42-7.51 (m, 1H), 7.39 (br s, 1H), 7.19-7.28 (m, 1H), 2.43 (s, 3H), 2.32 (s, 3H). Example A1—Inhibition of PF4 Tetramer Formation

[0831] Compounds of Examples 1-38, 65-301, 303, 305, 307, 309, 311, 313, 314, 316, and 318-404 were tested using SDS PAGE analysis of BS3 crosslinked PF4 for their ability to prevent PF4 tetramer formation. ULCs containing PF4 tetramers were distinguished from PF4 alone using dynamic light scattering (DLS). See, Suvana et al., *Throm. Res*, 122:211-220 (2008), which is hereby incorporated by reference, at least for a detailed description of this technique.

[0832] cDNA encoding human PF4 was cloned into the plasmid μ MT/BiPN5-His A (Invitrogen Corp., Carlsbad CA) for expression in the Drosophila Expression System (Invitrogen, Carlsbad, CA). Cloning was performed using Bg1 II and Age I cloning sites. A hexanucleotide encoding Bg1 II site was then eliminated by site-directed mutagenesis so that the expressed protein contained full-length wild type (wt) PF4 or PF4.sup.K50E with an identical sequence as their counterparts expressed in *E. coli*. See, method described in Sachais et al (Sachais, B. S. et al. (2012). *Blood* 119(25): 5955-5961). PF4 expression was induced by adding copper sulfate (0.5 mM). The induced S.sub.2 cells were incubated in serumfree Insect-Xpress™ media (Lonza, Walkersville, MD) for 3-5 days; supernatants were collected, sodium azide (0.02% final concentration) and EDTA (2.5 mM final concentration) were added, and the media were filtered through an Express® PLUS 0.22 μ m filter (Millipore Corp., Billerica, MA).

[0833] Wild-type (WT) human PF4 in the pT7-7 vector (Novagen, Madison, WI) was expressed in the *Escherichia coli* strain BL21DE30 pLysS (Stratagene, La Jolla, CA), and purified and characterized as described by Rauova et al. (Rauova, L. et al. (2006). *Blood* 107(6): 2346-2353) and Park et al., (*Blood*, 75:1290-1295 (1990)), which are hereby incorporated by reference. Briefly, recombinant protein was isolated from the supernatant of the bacterial lysate by affinity chromatography using a HiTrap high-performance (HP) affinity column. WT PF4 was purified from the media on a heparin HiTrap® column on an ÄTKAPrime™ system (GE Healthcare) at 4° C. in Tris (10 mM), EDTA (1 mM), and pH 8 buffer. Media was loaded in buffer containing NaCl (0.5 M) and PF4 was eluted at 1.8 M NaCl using a linear gradient. Fractions containing purified PF4 as detected by silver staining of 12% NuPAGE Bis-Tris gels (Invitrogen) were pooled, concentrated and buffer exchanged into 50 mM HEPES, 0.5 M NaCl, pH—7.2 using an Amicon® Ultra centrifugal filter (3K NMWL, Millipore Corp). Protein was quantified using a BCA assay.

Experiment 1

[0834] Compounds of Examples 1-38, 65-196, and 209-228 were then tested for their ability to inhibit PF4 tetramer formation using a cross-linking assay as described in Rauova cited above. Specifically, hPF4 (10 μ g/ml) in phosphate-buffered saline (PBS) was incubated at 37° C. for 15 min in the absence of the antagonistic compounds (control sample) and presence of compounds. Cross-linking and SDS-PAGE analysis were then performed as described in “Analysis of PF4 multimerization” of Rauova. The relative amounts of PF4 in each of the monomer, dimer, trimer and tetramer form were calculated by analyzing the samples on a 12% SDS-polyacrylamide gel under reducing conditions. Bands were quantified using the Kodak ID Image Analysis system (Kodak, Rochester, NY). The SigmaMarker™ reagent served as the molecular weight standard. Data was compiled and bar graphed as % PF4 for the tetramer, trimer, dimer, and monomer as a function of concentration for the test and control samples. These data show that certain compounds were effective in inhibiting PF4 tetramer formation at tested concentrations.

Experiment 2

[0835] This experiment was performed in a manner similar to experiment 1, but PF4 (10 μ g/ml) in PBS was independently incubated with compounds of Examples 1-38, 65-196, and 209-228 for 60 min at room temperature, followed by the addition of cross-linking reagent bis(sulfosuccinimidyl)suberate (0.2 mM) for 30 min at room temperature. The reaction was stopped by adding NuPAGE® lithium dodecyl sulfate (LDS) sample buffer, and denatured by heating to 70° C. for 10 min according to the manufacturer's instructions. The analysis and compilation of the data also was performed as described above in Experiment 1. Table 1 shows the data for the PF4

tetramerization of these compounds.

The IC.SUB.50 .data for inhibition of PF4 tetramerization is shown in Table 1 below

[0836] In general, the active compounds are acidic and have low log P values. The clog P (pH 7.4) calculated values range from 1.7 to -13 and therefore should generally have good aqueous solubility. Since most compounds are bis-acids, with pKa values ranging from 6.5 to -1.7 , most should have poor cell permeability. These characteristics are beneficial for IV administration and also for engagement of the molecular target PF4 which is a blood protein. For example, the compound in Example 1 has an experimentally determined log D value of 0.53 and a pKa of 1.99. It has experimentally determined kinetic solubility of $>200 \mu\text{M}$ at pH 7.4.

Example A2—Inhibition of Formation of Ultra Large Complexes (ULC) of PF4 Tetramers And Heparin

[0837] Since ULCs are formed as part of a dynamic equilibrium between heparin and PF4, dynamic light scattering (DLS) was performed to measure the ability of the exemplified compounds to disrupt preformed ULCs. Samples were analyzed and included PF4 incubated in the absence or presence of unfractionated heparin (UFH) for 20 min at room temperature at PF4 to heparin ratios (PHR) of 1:0 (no heparin), 2:1, and 0.64:1. The samples were then analyzed using photon correlation spectroscopy on a DynaPro® DLS instrument and Dynamics® software (V6.7.6; Microsoft) to obtain correlation function. The results of the DLS analysis indicate the percentage of ULCs and small PF4 particles. Data for the small particles (a population of particles with a mean hydrodynamic diameter of about 1 nm) and data for the large particles (a population of particles with a mean hydrodynamic diameter of about 300 nm) is assessed. Data are expressed as the percent of total intensity from each measurement, the mean of 10 measurements, and representative of two such experiments. Larger amounts of heparin result in the disruption of larger particles, i.e., ULCs, demonstrated by the presence of virtually all of the PF4 as small particles (data not shown).

[0838] Since the PF4 antagonists discussed herein are capable of disrupting preformed ULCs, the following experiment was performed to determine if the exemplified compounds inhibit formation of ULCs.

[0839] ELISA measurement and gel filtration measurement of ULC inhibition were performed as described in International Patent Publication No. WO2013/142328, which is incorporated herein by reference. Similarly, assays in which heparin concentrations are varied to determine the effect on ULC inhibition were performed as described in that publication.

[0840] Certain compounds were evaluated for their ability to inhibit formation of ultra large complexes (ULC) between PF4 tetramers and heparin. The results are illustrated in Table 2 below.

.sup.aIC.sub.50 values are $\pm 20\%$. .sup.bCells are exposed to compounds for 1 hour in the absence of serum. Compounds are removed and metabolically active cells are measured using MTS reduction, $N = 3$. None of the tested compounds were cytotoxic. This observation is in line with the finding of the previous example that the exemplified compounds apparently lack the ability to permeate cell membranes.

Example A3—Modulation of Antibody Binding to ULC

[0841] The effect of the exemplified compounds on antibody binding to intact ULCs was evaluated. ULC were formed as described above, with the exception that the PF4 was incubated with heparin for 30 min. Certain compounds (1 mM) were then added to wells pre-coated with KKO (monoclonal hit like antibody). These solutions were then incubated in the KKO wells overnight at 37°C . Antibody binding was detected by adding HRP (horseradish peroxidase)-conjugated sheep polyclonal anti-human PF4 antibody and developed with TMB substrate. After stopping the enzymatic reaction with 1M H.sub.3PO.sub.4, absorbance was measured at 450 nm in

a Packard SpectraCount™ plate reader.

Example A4—Inhibition of Platelet Activation and Serotonin Release Assay

[0842] Since one of the therapeutic goals of using ULC antagonists in patients with HIT is to prevent activation, compounds were evaluated for the ability to inhibit platelet activation. Data were generated using a serotonin release assay as described in Hirschman, Br. J. Haematol., 24(6):793-802 (1973), and Rauova and Cines, N. Engl. J. Med., 303:788-795 (1980), which are hereby incorporated by reference. See also WO2013/142328.

[0843] In this assay, platelet rich plasma (PRP) from healthy donors was incubated with 0.5 μ L .sup.14C-5-hydroxytryptamine creatinine sulfate (GE Life Sciences, Piscataway, NJ) per milliliter of PRP for 20 min at 37° C. to produce .sup.14C-labeled platelets. Serotonin uptake is inhibited by adding 1 mmol/ml imipramine (Sigma-Aldrich, St. Louis, MO) to the PRP. The radiolabeled platelets are mixed with KKO (170 μ g/ml) or with known platelet-activating HIT plasma in the absence (buffer control) or presence of a selected PF4 antagonist compound of Table 1 (2.5-3.0 mM).

[0844] Negative and positive controls contain sera from patients previously known to have negative or positive serotonin release, respectively. The assay was performed in the presence of heparin (1.0 U/ml), i.e., heparin added to the positive control serum, and in the absence of heparin (background). The percent release of serotonin is calculated for all conditions. Negative controls without antibody were studied in parallel. .sup.14C-5-hydroxytryptamine released from platelets was measured by scintillation counter. Data are expressed as % maximal release of radioactivity with release by the positive control plasma and 1.0 U/ml heparin defined as 100%. Compounds that inhibit platelet activation by KKO are measured by the serotonin release assay. (Rauova, L. (2005). Blood 105(1): 131-138).

Example A5—ADMET (Absorption, Distribution, Metabolism, Excretion and Toxicity) Properties

[0845] Certain exemplified compounds were examined for ADMET (absorption, distribution, metabolism, excretion and toxicity) profiling using conventional assays with the results shown in the Tables 3A-3C below.

[0846] As shown by Tables 3A-3C, for representative compounds described herein, no serious ADMET issues have arisen and the compounds meet drug property criteria for intravenous administration.

[0847] Compounds of Example 1, Example 3 and Example 20 showed excellent stability and low intrinsic clearance in mouse and human microsome assays. In addition, Example 3 showed good aqueous solubility and high protein binding. Examples 1 and 3 were evaluated as inhibitors of the five P450s that are the source of most DDI issues. Both compounds showed good profiles with no inhibition of 2C19, 2D6 or 3A4 midazolam and only moderate inhibition of 2C9. Example 1 had moderate inhibition of 1A2 as well. These two compounds were also evaluated in a hERG patch

clamp assay and no significant inhibition was observed at 30 μ M concentration. The tested compounds meet drug property criteria for IV administration.

Example A6—Pharmacokinetic Parameters

[0848] Table 4 shows the results in pharmacokinetic (PK) parameters for compound of Example 1 after CD-1 mice were administered an intravenous bolus dose of the compound at 1 mg/kg (0.500 mg/ml in 5% DMSO/95% PBS (pH8)) for an average of 3 mice. PK parameters were measured and reported in Table 4 as follows: C.sub.0 represents concentration in ng/ml at t=0 min; AUC.sub.0-last represents area under the curve for t=0 min to last time point; AUC.sub.0- ∞ represents area under the curve for t=0 min to infinity.

TABLE-US-00006 TABLE 4 PK Parameters Volume of AUC.sub.0-last AUC.sub.0- ∞ distribution Clearance t.sub.1/2 (hr) C.sub.0 (ng/ml) (ng*h/ml) (ng*h/ml) (Vd.sub.ss) in L/kg (ng/ml) 4.59 $\pm$ 0.584 15078 $\pm$ 2071 9188 $\pm$ 704 9348 $\pm$ 778 0.448 $\pm$ 0.0121 1.79 $\pm$ 0.147

[0849] Compound of Example 1 showed a long half-life, low clearance and volume of distribution (see Table 4), all good parameters for an IV drug interacting with an extracellular blood protein. The concentration of Example 1 was sustained above 1 μ M for greater than 4 hours at 1 mg/kg (see FIG. 5).

Example A7—In Vivo Activity

[0850] Heparin-PF4-KKO mice that were induced to thrombocytopenia were administered the compound of Example 1. The dosing regimen was guided by the PK results in Table 4 (see Example A6). At T.sub.0hr, 5 mg/kg of Compound 1 was given by retro-orbital injection. 1000 units/kg heparin was injected subcutaneously at T.sub.3hr. At T.sub.4hr, 20 mg/kg of KK0 antibody was administered by retro-orbital injection. Also at T.sub.4hr, an additional 5 mg/kg of the compound was injected intraperitoneally. Platelet count was measured at T.sub.8hr.

[0851] Results are shown in the graph of FIG. 4. The mice tolerated the 5 mg/kg IV and IP doses of the compound well. Three of the four mice tested with the compound of Example 1 showed almost complete protection, with platelet counts 4 hr after KK0 administration at >80% of baseline, while the remaining mouse showed platelet counts at 4 hr only a little higher than DMSO controls. The results show that the compound of Example 1 reduced heparin-PF4-KK0 induced thrombocytopenia in vivo and ameliorated the low platelet count seen with vehicle control.

Example A8—P-Selectin Inhibition Assay

[0852] FIGS. 8 and 9 show that in human platelet activation assays, compounds of examples 15, 11, 31, 29, 33, 34, 22, 18, 28 and 32 are inhibitory.

[0853] FIG. 22 shows that the compounds of Examples 31, 29, 44, 34, 22, 28, 36 and 32 modulate the activity of normalized P-selectin.

Experimental Protocol

[0854] Fc γ RIIA transgenic murine blood was drawn from inferior vena cava under anesthesia into a 1 ml syringe with 10% volume of acid citrate dextrose (ACD). Whole blood was diluted with 1 $\times$ Tyrode buffer (5 mM N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid, 0.1% BSA, 134 mM NaCl, 0.3 mM NaH.sub.2PO.sub.4, 3 mM KCl, 2 mM MgCl.sub.2, 12 mM NaHCO.sub.3, 5 mM glucose) with 0.02 U/ml apyrase and 1 μ M PGE1 and centrifuged at 100 g for 10 min. Platelet rich plasma (PRP) was carefully removed and centrifuged at 1000 g for 5 min. Platelet pellet was resuspended in Tyrode buffer with 0.02 U/ml apyrase at 2 $\times$ 10⁸/ml concentration at 37° C. PF4 antagonists are diluted in Tyrode buffer, and are incubated with 10 μ g/ml human PF4 purified protein at room temperature for 30 min. The PF4-drug complex is then incubated with 1 $\times$ 10⁸/ml platelets with 1 mM CaCl.sub.2, 0.1% BSA at 37° C. for 10 min. 40 μ g/ml KK0 and 10 μ g/ml anti-CD62P (P-selectin) antibodies are added into the reaction. One milliliter ice-cold PBS is added to each reaction after 5 min of incubation. Labelled platelets are then analyzed by a BD Accuri C6 flow cytometer. The results are represented by both the mean fluorescence intensity and by the percentage of positive platelets.

Example A9—P-Selectin Levels in Human Platelets

[0855] FIGS. 10-13 show effect of PF4 concentration, a combination of PF4 and heparin, and a combination of PF4 and example 15 on P-selectin levels in human platelets.

Experimental Protocol

[0856] For 100 μ L reaction, add 2.5×10^7 /ml human platelets, add 1.5 mM CaCl₂, 37.5 μ g/ml or 65 μ g/ml PF4, 10 p/ml heparin (2 μ L of 500 U/ml), with or without 100 μ M of the exemplified compound (5 μ L of 2 mM) for 30 min. Add KKO at 50 μ g/ml (2 μ L 2.6 mg/ml KKO) all at RT for 20 min. FL2-A is P-selectin.

Example A10—P-Selectin Levels in the HIT Mouse Model

[0857] FIGS. 14-21 show efficacy of exemplified compounds 33, 34, 22, 32, 28, 36, 31 and 29 in preventing P-selectin expression in Fc γ RIIA transgenic murine platelets.

Experimental Protocol

[0858] 37.5 μ g/ml PF4 with/without 50 μ M of the exemplified compound incubated with 3×10^7 /ml platelets; 50 μ g/ml KKO.
