# VIDEO PROCESSING METHOD AND APPARATUS, ELECTRONIC DEVICE, AND STORAGE MEDIUM

## CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a national stage of International Application No. PCT/CN2022/094744, filed on May 24, 2022, which claims priority to Chinese Patent Application No. 202110926600.0, filed on Aug. 12, 2021. The disclosures of both of the aforementioned applications are hereby incorporated by reference in their entireties.

## TECHNICAL FIELD

This application relates to the technical field of video shooting, and in particular to a video processing method and apparatus, an electronic device, and a storage medium.

## BACKGROUND

With the development of technologies, users have increasingly high requirements for effects and styles of videos shot through terminals such as mobile phones. However, in a current mobile phone, a filter principle in a shooting mode is usually used for a filter used to capture a video, and a video processed by the filter cannot meet a high color grading requirement.

## SUMMARY

A video processing method and apparatus, an electronic device, and a storage medium are provided, to enable, based on a characteristic of a LUT, a video shot through the electronic device to present a different style effect, meeting a higher color grading requirement.

According to a first aspect, a video processing method is provided. The method includes: determining one video style template among a plurality of video style templates, where each video style template is corresponding to a preset look up table LUT; obtaining a video shot through a camera; processing the video shot through the camera by using a logarithm LOG curve corresponding to a current photosensitivity ISO of the camera, to obtain a LOG video; and processing the LOG video based on a 2D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a first frame rate, to obtain a video corresponding to the determined video style template; or processing the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the determined video style template, where the first frame rate is greater than the second frame rate.

In a possible implementation, a process of processing the LOG video based on a 2D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a first frame rate, to obtain a video corresponding to the determined video style template is performed in HSV color space. Therefore, the 2D-LUT is used based on a characteristic of the HSV color space.

In a possible implementation, a process of processing the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a second frame rate, to

2

obtain a video corresponding to the determined video style template includes: establishing cube interpolation space based on the LUT; determining a cube to which each pixel in the LOG video belongs in the cube interpolation space, where the cube is divided into six tetrahedrons; determining a tetrahedron to which each pixel in the LOG video belongs; converting a pixel value of a pixel corresponding to a vertex of a cube into a pixel value obtained by LUT processing; and performing interpolation, based on the tetrahedron to which each pixel belongs, on a pixel not corresponding to the vertex of the cube, and converting the pixel value into a pixel value obtained by LUT processing.

In a possible implementation, before a process of processing the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the determined video style template, the method further includes: converting the LOG video from a LOG video in RGB color space to a LOG video in YUV color space; and performing YUV denoising on the LOG video in the YUV color space, to obtain a denoised LOG video. Because noise is introduced into the LOG video when the video is processed by using the LOG curve, the LOG video may be converted into a LOG video in the YUV color space and then subject to YUV denoising, and the noise is reduced by an algorithm, to improve quality of a video image.

In a possible implementation, before a process of processing the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the determined video style template, the method further includes: converting the denoised LOG video from a LOG video in the YUV color space to a LOG video in the RGB color space; and after a process of processing the LOG video based on a LUT corresponding to the determined video style template, to obtain a video corresponding to the determined video style template, the method further includes: converting a video that is in the RGB color space and that is corresponding to the determined video style template into a video in the YUV color space.

In a possible implementation, when a capture frame rate of the video shot through the camera is a first frame rate, a video corresponding to a determined video style template is divided into two streams. One stream is stored, and the other stream is previewed. This can enable a previewed video and a finally obtained video to have a same visual effect, to help a user preview a video based on a style after color grading.

In a possible implementation, the first frame rate is 120 frames per second FPS or 60 FPS, and the second frame rate is 30 FPS.

According to a second aspect, a video processing apparatus is provided. The video processing apparatus includes: a processor and a memory. The memory is configured to store at least one instruction. The instruction is loaded and executed by the processor to implement the foregoing video processing method.

According to a third aspect, an electronic device is provided. The electronic device includes: a camera and the foregoing video processing apparatus.

According to a fourth aspect, a computer-readable storage medium is provided. The computer-readable storage medium stores a computer program. When the computer program is run on a computer, the computer is enabled to perform the foregoing video processing method.

In the video processing method and apparatus, the electronic device, and the storage medium in the embodiments of this application, during video recording, the LOG video is processed by using a LUT technology in a movie industry and based on the LUT corresponding to the determined video style template. This enables a recorded video to have a style effect corresponding to the determined video style template, to meet a high color grading requirement, and enables the recorded video to have movie quality. In addition, when a capture frame rate of a video is low, the 3D-LUT is used to process the video, to implement color control more accurately. When the capture frame rate of a video is high, the 2D-LUT is used to process the video, to implement LUT processing within a limited frame interval.

### BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of a structure of an electronic device according to an embodiment of this application;

FIG. 2 is a flowchart of a video processing method according to an embodiment of this application;

FIG. 3 is a schematic diagram of a user interface in a movie mode according to an embodiment of this application;

FIG. 4 is a schematic diagram of a LOG curve according to an embodiment of this application;

FIG. 5 is a specific flowchart of step 104 in FIG. 2;

FIG. 6 is a schematic diagram of relations between cubes and tetrahedrons in cube interpolation space according to an embodiment of this application;

FIG. 7 is a flowchart of another video processing method according to an embodiment of this application;

FIG. 8 is a schematic diagram of a UV plane;

FIG. 9 is a block diagram of another structure of an electronic device according to an embodiment of this application;

FIG. 10 is a block diagram of another structure of an electronic device according to an embodiment of this application;

FIG. 11 is a block diagram of a software structure of an electronic device according to an embodiment of this application; and

FIG. 12 is a schematic diagram of a user interface in a professional mode according to an embodiment of this application.

### DETAILED DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

Terms used in implementations of this application are merely intended to explain specific embodiments of this application, but are not intended to limit this application.

Before introducing embodiments of this application, an electronic device in the embodiments of this application is first described. As shown in FIG. 1, the electronic device 100 may include a processor 110, camera 193, displays 194, and the like. It may be understood that a structure shown in this embodiment of the present invention does not constitute a specific limitation on the electronic device 100. In some other embodiments of this application, the electronic device 100 may include more or fewer components than those shown in the figure, combine some components, split some components, or have a different component arrangement. The components shown in the figure may be implemented in hardware, software, or a combination of software and hardware.

The processor 110 may include one or more processing units. For example, the processor 110 may include a graphics

processing unit (graphics processing unit, GPU), an image signal processor (image signal processor, ISP), a controller, a video codec, a digital signal processor (digital signal processor, DSP), and the like. Different processing units may be separate devices or may be integrated into one or more processors. The controller may generate an operation control signal based on instruction operation code and a time sequence signal, to complete control of instruction fetching and instruction execution. A memory may be further disposed in the processor 110 and is configured to store instructions and data.

The electronic device 100 implements a display function by using the GPU, the displays 194, an application processor, and the like. The GPU is a microprocessor for image processing and is connected to the displays 194 and the application processor. The GPU is configured to perform mathematical and geometric computation and render a graph. The processor 110 may include one or more GPUs and execute program instructions to generate or change display information.

The electronic device 100 may implement a shooting function by using the ISP, the camera 193, the video codec, the GPU, the displays 194, the application processor, and the like.

The ISP is configured to process data fed back by the camera 193. For example, during shooting, a shutter is pressed, and light is transmitted to a photosensitive element of the camera through a lens. An optical signal is converted into an electrical signal, and the photosensitive element of the camera transmits the electrical signal to the ISP for processing, to convert the electrical signal into a visible image. The ISP may further perform algorithm optimization on noise, luminance, and complexion of the image. The ISP may further optimize parameters such as exposure and a color temperature in a shooting scene. In some embodiments, the ISP may be disposed in the camera 193.

The camera 193 is configured to capture a still image or a video. An optical image of an object is generated through the lens and is projected onto the photosensitive element. The photosensitive element may be a charge coupled device (charge coupled device, CCD) or a complementary metal-oxide-semiconductor (complementary metal-oxide-semiconductor, CMOS) phototransistor. The photosensitive element converts the optical signal into the electrical signal and then transmits the electrical signal to the ISP to convert the electrical signal into a digital image signal. The ISP outputs the digital image signal to the DSP for processing. The DSP converts the digital image signal into an image signal in a standard format such as RGB or YUV. In some embodiments, the electronic device 100 may include one or N camera 193, where N is a positive integer greater than 1.

The digital signal processor is configured to process a digital signal and may process another digital signal in addition to the digital image signal. For example, when the electronic device 100 selects a frequency, the digital signal processor is configured to perform Fourier transformation or the like on frequency energy.

The video codec is configured to compress or decompress a digital video. The electronic device 100 may support one or more video codecs. In this way, the electronic device 100 may play or record videos in a plurality of encoding formats, for example, moving picture experts group (moving picture experts group, MPEG)1, MPEG2, MPEG3, and MPEG4.

As shown in FIG. 2, an embodiment of this application provides a video processing method. The video processing method may be performed by a processor 110, that is, an ISP

or a combination of the ISP and another processor. The video processing method includes the following steps.

Step 101: Determine one video style template among a plurality of video style templates, where each video style template is corresponding to a preset look up table (Look Up Table, LUT).

The LUT is essentially a mathematical transformation model. An image data value may be output as another image data value by using the LUT, to change an exposure and a color of an image. LUTs corresponding to different video styles may be generated in advance. Before recording a video, the electronic device first determines a video style template. For example, the electronic device may determine the video style template based on a selection of a user or automatically determine the video style template based on a scene corresponding to an image obtained by a current camera through artificial intelligence (Artificial Intelligence, AI). For example, it is assumed that the electronic device is a mobile phone, in a possible implementation, as shown in FIG. 3, a user operates the mobile phone to display a shooting interface. The shooting interface includes a movie mode option. When the user further selects the movie mode option to display a movie mode, a corresponding movie mode interface includes a plurality of video style template options, including, for example, a style template of a movie "A", a style template of a movie "B", and a style template of a movie "C". Only the style template of a movie "A" is shown in the user interface shown in FIG. 3. It may be understood that a plurality of different movie style templates may be displayed side by side in the user interface. LUTs corresponding to different movie style templates may be generated in advance based on corresponding movie color matching styles, and color conversion of the LUTs has a style characteristic of a corresponding movie. For example, a color matching style of the movie "A" is a complementary color. The complementary color means that two corresponding colors form a contrast effect. Contrast is emphasized by two colors of a warm color system and a cold color system, to improve a bright and prominent effect. Usually, two contrasting colors symbolize a conflicting behavior. Through presentation of external complementary colors, that a role is in a conflict state or an exhausted state is expressed. A LUT corresponding to the style template of the movie "A" is used for presenting the complementary colors more distinctly after color mapping is transformed, to simulate the color matching style of the movie "A". In a possible implementation, as shown in FIG. 3, the user operates the mobile phone to display the movie mode, and the mobile phone obtains an image currently shot through a camera, determines a scene corresponding to the image according to an AI algorithm, and determines a recommended video style template corresponding to the scene. For example, if it is recognized that a subject of a currently shot image is a young female character, the corresponding recommended video style template is determined to be the style template of the movie "C" according to the algorithm. The movie "C" is a movie themed on the young female character, and a color matching style of the movie "C" may be simulated for a corresponding LUT. For example, if it is recognized that a currently shot image is a city street, the corresponding video style template is determined to be the style template of the movie "B" according to the algorithm. The movie "B" is a movie with a city street as a main scene, and a color matching style of the movie "B" may be stimulated for a corresponding LUT. In this way, a video style template conforming to a current scene may be automatically recom-

mended to the user. A LUT appropriate for a mobile electronic device may be generated by pre-extraction from the movie style.

Step 102: Obtain a video shot through a camera. For example, after determining the video style template in step 101, if the user taps a shooting option, the mobile phone starts to obtain the video shot through the camera.

Step 103: Process, by using a logarithm (Logarithm, LOG) curve corresponding to a current photosensitivity ISO of the camera, the video shot through the camera, to obtain a LOG video.

The LOG curve is a scene-based curve, and the LOG curve is slightly different in different ISOs. As the ISO increases, a maximum value of the LOG curve is also increased. When the ISO is increased to a level, a highlight is presented in a shoulder shape, keeping the highlight from overexposure. FIG. 4 shows a LOG curve in which an abscissa is a linear signal, expressed by a 16-bit coded value (Code Value), and an ordinate is a LOG signal processed by using the LOG curve, expressed by a 10-bit coded value. Through processing by using the LOG curve, a signal input of a camera may be used for encoding information of a dark interval to a middle tone (as shown in a steep part of the curve in FIG. 4), to form 10-bit signal output. This conforms to a LOG sensing rule for light by human eyes, and keeps information of a dark part maximally. For a LOG video, a limited bit depth may be used for keeping details of a shadow and a highlight maximally. An ASA in FIG. 4 is photosensitivity, and different ASAs correspond to different ISOs, both of which belong to different standards.

Step 1041: Process the LOG video based on a 2D-LUT corresponding to the determined video style template when a capture (capture) frame rate of the video shot through the camera is a first frame rate, to obtain a video corresponding to the determined video style template.

Step 1042: Process the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the determined video style template. The first frame rate is greater than the second frame rate.

Specifically, after the LOG video is obtained, the LOG video is used as an input, to be used in the LUT corresponding to the video style template determined in step 101. Mapping conversion is performed on a LOG video image. After mapping conversion, the video corresponding to the determined video style template may be obtained. A video output by processing the LOG video based on a LUT may be a video with a Rec.709 color standard or a video with a high-dynamic range (High-Dynamic Range, HDR) 10 standard. In other words, the video may be converted into a video with the HDR10 standard by processing the LOG video by using the LUT.

The capture frame rate means a read-out frame rate of a sensor of a camera or a shooting frame rate of a video. For video recording, a frame rate during shooting by the camera affects a video effect. For example, shooting at a higher-than-normal frame rate is a technical means in movie shooting, and can achieve different effects. When a capture frame rate of a video is greater than a play frame rate, it is referred to as shooting at a higher-than-normal frame rate. For example, a frame rate during video playing is 30 frames per second, that is, the frame rate is 30 frames per second (Frames Per Second, FPS), while a frame rate during shooting is 60 FPS, which is referred to as shooting at a higher-than-normal frame rate. An effect that can be achieved by shooting at a higher-than-normal frame rate is a slow

motion. In shooting at a higher-than-normal frame rate, a frame rate during shooting by a camera is appropriate for different scene expressions. For example, shooting at a higher-than-normal frame rate of 60 FPS is appropriate for expressing scenes such as translation, walking slowly, laughing, and clapping, while shooting at a higher-than-normal frame rate of 120 FPS is appropriate for expressing scenes such as running, turning around, running a hand through hair, and scattering flowers. Therefore, during video recording, a user may select shooting at a higher-than-normal frame rate, or perform shooting at a high frame rate in another manner. As a capture frame rate of a video shot through a camera is faster, a frame interval is shorter. This requires that a processing speed during video recording is faster. At a capture frame rate of 60 FPS, a time for which an LUT is to be used for processing a video is within 15 ms. At a capture frame rate of 120 FPS, a time for which an LUT is to be used for processing a video is within 8 ms. The LUT may be a 3D-LUT or 2D-LUT. Compared with the 2D-LUT, the 3D-LUT may implement color control more accurately. However, a long time is required for processing when the 3D-LUT is used due to algorithm complexity, while a short time is required for processing when the 2D-LUT is used. Therefore, in this embodiment of this application, when the capture frame rate of the video shot through the camera is a high first frame rate, the 2D-LUT is used, to implement LUT processing within a limited frame interval. When the capture frame rate of the video shot through the camera is a low second frame rate, the 3D-LUT is used, to implement LUT processing within a sufficiently long frame interval, implementing color control more accurately. It should be noted that this embodiment of this application is not limited to shooting at a higher-than-normal frame rate, and this embodiment of this application is also applicable to other ways in which a high capture frame rate is required.

Different LUTs are used for the electronic device, and related modules in the electronic device may be matched, to be adapted to LUTs of different styles. For example, if the determined video style template in step 101 is a gray-tone video style template, a gray-tone image is characterized with a strong texture feeling, a low saturation, no more color interference except a color of a person's skin, and a cold color of a dark part. Based on these characteristics, the electronic device may adjust related module parameters while recording a video, keep a texture in an image without strong denoising and sharpening, appropriately reduce the saturation of the image, keep real restoration of a skin color in the image, and adjust the dark part of the image to a cold color.

In the video processing method in this embodiment of this application, during video recording, the LOG video is processed by using a LUT technology in a movie industry and based on the LUT corresponding to the determined video style template. This enables a recorded video to have a style effect corresponding to the determined video style template, to meet a high color grading requirement, and enables the recorded video to have movie quality. In addition, when a capture frame rate of a video is low, the 3D-LUT is used to process the video, to implement color control more accurately. When the capture frame rate of a video is high, the 2D-LUT is used to process the video, to implement LUT processing within a limited frame interval.

In a possible implementation, as shown in FIG. 5, a process of step 1042: processing the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the

camera is a second frame rate, to obtain a video corresponding to the determined video style template includes:

Step 10421: Establish cube interpolation space based on a LUT, where the LUT is a 3D-LUT.

Implementation of the 3D-LUT is performed in the RGB domain, and the 3D-LUT is a color grading and mapping relationship commonly used in a movie industry. An arbitrarily input RGB pixel value may be converted into a corresponding another RGB pixel value. For example, if a 12-bit RGB video image is input, a 12-bit RGB video image is output after LUT processing and mapping. In step 1041, entire RGB color space is evenly divided into, for example,  $33 \times 33 \times 33$  cubes, corresponding to LUTs. A side length step\_size of each cube is, for example,  $2^{(12-5)} = 2^7$ .

Step 10422: Determine a cube to which each pixel in the LOG video belongs in the cube interpolation space, where the cube is divided into six tetrahedrons.

The LOG video is used as an input during LUT processing. A pixel is obtained by processing and mapping each pixel in an image of the LOG video by using the LUT, that is, a process of processing the LOG video by using the LUT may be implemented. In step 10422, a cube to which each pixel in each LOG video as an input belongs in the foregoing cube interpolation space is to be determined, and the cube is divided into six tetrahedrons.

Step 10423: Determine a tetrahedron to which each pixel in the LOG video belongs.

Step 10424: Convert a pixel value of a pixel corresponding to a vertex of a cube into a pixel value obtained by LUT processing, perform interpolation, based on the tetrahedron to which each pixel belongs, on a pixel not corresponding to the vertex of the cube, and converting the pixel value into a pixel value obtained by LUT processing.

Specifically, if an input pixel is located at a vertex of a cube, a mapped RGB pixel value may be directly obtained based on an index of the vertex and a 3D-LUT, that is, a pixel value of the pixel may be mapped and converted into a corresponding pixel value directly by using the LUT. If the pixel is located between vertices of the cube, interpolation is performed based on the tetrahedron to which the pixel belongs.

In a possible implementation, as shown in FIG. 6, a cube has a  $0^{th}$  vertex to a  $7^{th}$  vertex, which are respectively expressed by numbers 0 to 7 in FIG. 6. A direction from the  $0^{th}$  vertex to a  $1^{st}$  vertex is a coordinate axis direction of a blue B channel. A direction from the  $0^{th}$  vertex to a  $4^{th}$  vertex is a coordinate axis direction of a red R channel. A direction from the  $0^{th}$  vertex to a  $2^{nd}$  vertex is a coordinate axis direction of a green G channel. The  $0^{th}$  vertex, the  $1^{st}$  vertex, the  $2^{nd}$  vertex, and a  $3^{rd}$  vertex are located in a same plane. The  $1^{st}$  vertex, the  $3^{rd}$  vertex, a  $5^{th}$  vertex, and the  $7^{th}$  vertex are located in a same plane. The  $4^{th}$  vertex, the  $5^{th}$  vertex, a  $6^{th}$  vertex, and the  $7^{th}$  vertex are located in a same plane. The  $0^{th}$  vertex, the  $2^{nd}$  vertex, the  $4^{th}$  vertex, and the  $6^{th}$  vertex are located in a same plane. The  $0^{th}$  vertex, the  $1^{st}$  vertex, the  $5^{th}$  vertex, and the  $7^{th}$  vertex form a first tetrahedron. The  $0^{th}$  vertex, the  $1^{st}$  vertex, the  $3^{rd}$  vertex, and the  $7^{th}$  vertex form a second tetrahedron. The  $0^{th}$  vertex, the  $2^{nd}$  vertex, the  $3^{rd}$  vertex, and the  $7^{th}$  vertex form a third tetrahedron. The  $0^{th}$  vertex, the  $4^{th}$  vertex, the  $5^{th}$  vertex, and the  $7^{th}$  vertex form a fourth tetrahedron. The  $0^{th}$  vertex, the  $4^{th}$  vertex, the  $6^{th}$  vertex, and the  $7^{th}$  vertex form a fifth tetrahedron. The  $0^{th}$  vertex, the  $2^{nd}$  vertex, the  $6^{th}$  vertex, and the  $7^{th}$  vertex form a sixth tetrahedron. Coordinates of an  $i^{th}$  vertex are (Ri, Gi, Bi), and a value of i is 0, 1, 2, 3, . . . , or 7. A pixel value of the  $i^{th}$  vertex obtained by LUT processing is VE (Ri, Gi, Bi), where E is R, G, and B respectively.

In step 1044, a process of performing interpolation, based on the tetrahedron to which each pixel belongs, on a pixel not corresponding to the vertex of the cube, and converting the pixel value into a pixel value obtained by LUT processing includes the following.

A pixel value  $VE(R, G, B)$  of a E channel obtained by LUT processing is generated based on a current pixel  $(R, G, B)$ , where E is R, G, and B respectively, and the current pixel means a pixel to be interpolated currently in an input LOG video.

$$VE(R, G, B) = VE(R_0, G_0, B_0) + (\text{delta\_valueR\_E} \times \text{deltaR} + \text{delta\_valueG\_E} \times \text{deltaG} + \text{delta\_valueB\_E} \times \text{deltaB} + (\text{step\_size} \gg 1)) / (\text{step\_size}).$$

$VE(R_0, G_0, B_0)$  is a pixel value of a E channel obtained by LUT processing at the  $0^{th}$  vertex  $(R_0, G_0, B_0)$ , where E is R, G, and B respectively.

$\text{delta\_valueR\_E}$  is a difference between pixel values of the E channel that are obtained by LUT processing and that are of two vertices in the coordinate axis direction of the R channel corresponding to the tetrahedron to which the current pixel belongs.  $\text{delta\_valueG\_E}$  is a difference between pixel values of the E channel that are obtained by LUT processing and that are of two vertices in the coordinate axis direction of the G channel corresponding to the tetrahedron to which the current pixel belongs.  $\text{delta\_valueB\_E}$  is a difference between pixel values of the E channel that are obtained by LUT processing and that are of two vertices in the coordinate axis direction of the B channel corresponding to the tetrahedron to which the current pixel belongs.

$\text{deltaR}$  is a difference between an R value in the current pixel  $(R, G, B)$  and an  $R_0$  value at the  $0^{th}$  vertex  $(R_0, G_0, B_0)$ ,  $\text{deltaG}$  is a difference between a G value in the current pixel  $(R, G, B)$  and a  $G_0$  value at the  $0^{th}$  vertex  $(R_0, G_0, B_0)$ , and  $\text{deltaB}$  is a difference between a B value in the current pixel  $(R, G, B)$  and a  $B_0$  value at the  $0^{th}$  vertex  $(R_0, G_0, B_0)$ .

$\text{step\_size}$  is a side length of the cube.

$\gg$  represents a right shift operation, and  $(\text{step\_size} \gg 1)$  represents a right shift of  $\text{step\_size}$  by one bit.

Specifically, for example, for the input current pixel  $(R, G, B)$ ,  $\text{deltaR}$ ,  $\text{deltaG}$ , and  $\text{deltaB}$  are calculated.  $\text{deltaR}$ ,  $\text{deltaG}$ , and  $\text{deltaB}$  represent distances between the current pixel  $(R, G, B)$  and the  $0^{th}$  vertex respectively, and  $\text{deltaR} = R - R_0$ ,  $\text{deltaG} = G - G_0$ , and  $\text{deltaB} = B - B_0$ . In step 1043, a tetrahedron to which the current pixel belongs may be determined based on a relationship between  $\text{deltaR}$ ,  $\text{deltaG}$ , and  $\text{deltaB}$ . If  $\text{deltaB} \geq \text{deltaR}$  and  $\text{deltaR} \geq \text{deltaG}$ , it is determined that the current pixel belongs to the first tetrahedron. If  $\text{deltaB} \geq \text{deltaG}$  and  $\text{deltaG} \geq \text{deltaR}$ , it is determined that the current pixel belongs to the second tetrahedron. If  $\text{deltaG} \geq \text{deltaB}$  and  $\text{deltaB} \geq \text{deltaR}$ , it is determined that the current pixel belongs to the third tetrahedron. If  $\text{deltaR} \geq \text{deltaB}$  and  $\text{deltaB} \geq \text{deltaG}$ , it is determined that the current pixel belongs to the fourth tetrahedron. If  $\text{deltaR} \geq \text{deltaG}$  and  $\text{deltaG} \geq \text{deltaB}$ , it is determined that the current pixel belongs to the fifth tetrahedron. If the relationship between  $\text{deltaR}$ ,  $\text{deltaG}$ , and  $\text{deltaB}$  does not meet any condition for the first tetrahedron to the fifth tetrahedron, it is determined that the current pixel belongs to the sixth tetrahedron. It is assumed that the current pixel  $(R, G, B)$  belongs to the first tetrahedron, during calculation of a pixel value  $VR(R, G, B)$  of the R channel of the pixel after LUT processing,  $\text{delta\_valueR\_E}$  is a difference between pixel values of the E channel that are obtained by LUT processing and that are of two vertices in the coordinate axis direction of the R channel corresponding to the tetrahedron to which the current pixel belongs, that is,

$\text{delta\_valueR\_R} = VR(R_5, G_5, B_5) - VR(R_1, G_1, B_1)$ ,  $\text{delta\_valueG\_R} = VR(R_7, G_7, B_7) - VR(R_5, G_5, B_5)$ ,  $\text{delta\_valueB\_R} = VR(R_1, G_1, B_1) - VR(R_0, G_0, B_0)$ ,  $VR(R, G, B) = VR(R_0, G_0, B_0) + (\text{delta\_valueR\_R} \times \text{deltaR} + \text{delta\_valueG\_R} \times \text{deltaG} + \text{delta\_valueB\_R} \times \text{deltaB} + (\text{step\_size} \gg 1)) / (\text{step\_size})$ . During calculation of a pixel value  $VG(R, G, B)$  of the G channel of the pixel after LUT processing,  $\text{delta\_valueG\_E}$  is a difference between pixel values of the E channel that are obtained by LUT processing and that are of two vertices in the coordinate axis direction of the G channel corresponding to the tetrahedron to which the current pixel belongs, that is,  $\text{delta\_valueR\_G} = VR(R_5, G_5, B_5) - VR(R_1, G_1, B_1)$ ,  $\text{delta\_valueG\_G} = VG(R_7, G_7, B_7) - VG(R_5, G_5, B_5)$ ,  $\text{delta\_valueB\_G} = VG(R_1, G_1, B_1) - VG(R_0, G_0, B_0)$ ,  $VG(R, G, B) = VG(R_0, G_0, B_0) + (\text{delta\_valueR\_G} \times \text{deltaR} + \text{delta\_valueG\_G} \times \text{deltaG} + \text{delta\_valueB\_G} \times \text{deltaB} + (\text{step\_size} \gg 1)) / (\text{step\_size})$ . During calculation of a pixel value  $VB(R, G, B)$  of the B channel of the pixel after LUT processing,  $\text{delta\_valueB\_E}$  is a difference between pixel values of the E channel that are obtained by LUT processing and that are of two vertices in the coordinate axis direction of the B channel corresponding to the tetrahedron to which the current pixel belongs, that is,  $\text{delta\_valueR\_B} = VB(R_5, G_5, B_5) - VB(R_1, G_1, B_1)$ ,  $\text{delta\_valueG\_B} = VB(R_7, G_7, B_7) - VB(R_5, G_5, B_5)$ ,  $\text{delta\_valueB\_B} = VB(R_1, G_1, B_1) - VB(R_0, G_0, B_0)$ ,  $VB(R, G, B) = VB(R_0, G_0, B_0) + (\text{delta\_valueR\_B} \times \text{deltaR} + \text{delta\_valueG\_B} \times \text{deltaG} + \text{delta\_valueB\_B} \times \text{deltaB} + (\text{step\_size} \gg 1)) / (\text{step\_size})$ . If the current pixel  $(R, G, B)$  belongs to another tetrahedron, the calculation process is similar, and a difference lies in calculation of  $\text{delta\_valueR\_E}$ . For example, for the second tetrahedron,  $\text{delta\_valueR\_R} = VR(R_7, G_7, B_7) - VR(R_3, G_3, B_3)$ ,  $\text{delta\_valueG\_R} = VR(R_3, G_3, B_3) - VR(R_1, G_1, B_1)$ ,  $\text{delta\_valueB\_R} = VR(R_1, G_1, B_1) - VR(R_0, G_0, B_0)$ . The calculation process based on the another tetrahedron is not described herein in detail.

In a possible implementation, a process of step 1041: processing the LOG video based on a 2D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a first frame rate, to obtain a video corresponding to the determined video style template is performed in HSV color space.

Specifically, when the capture frame rate of the video shot through the camera is the first frame rate, that is, when the LOG video is processed based on the 2D-LUT, the 2D-LUT is obtained by 3D-LUT simulation in advance. For example, the 3D-LUT and corresponding input data and output data of the 3D-LUT are known in advance, and both the input data and output data belong to RGB color space. In this case, the input data may be converted from the RGB color space to the HSV color space, and the output data may be converted from the RGB color space to the HSV color space. Through a conversion relationship of data in the HSV color space, a specific model of the 2D-LUT may be obtained, to facilitate use of the 2D-LUT during video recording. Because conversion may be implemented based on only two variables in the 2D-LUT, a tone H and saturation S may be converted, and a luminance V may be ignored, to achieve an effect of 3D-LUT simulation for the 2D-LUT.

In a possible implementation, as shown in FIG. 7, before a process of step 1042: processing the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the determined video style template, the method further includes: Step 105: Convert the LOG video from a LOG video in RGB color space to a LOG video in

## 11

YUV color space; and Step **106**: Perform YUV denoising on the LOG video in the YUV color space, to obtain a denoised LOG video. The LOG video using the LUT in step **1042** is the LOG video obtained by YUV denoising in step **106**. Because noise is introduced into the LOG video obtained in step **103**, the LOG video may be converted into a LOG video in the YUV color space and then subject to YUV denoising, and the noise is reduced by an algorithm, to improve quality of a video image.

In a possible implementation, as shown in FIG. 7, before a process of step **1042**: processing the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the determined video style template, the method further includes: Step **107**: Convert the denoised LOG video from the LOG video in the YUV color space to the LOG video in the RGB color space. After a process of step **104**: processing the LOG video based on a LUT corresponding to the determined video style template, to obtain a video corresponding to the determined video style template, the method further includes: Step **108**: Convert a video that is in the RGB color space and that is corresponding to the determined video style template into a video in the YUV color space. Because a process of processing the LOG video based on a LUT in step **1042** is implemented based on the RGB color space, before step **1042**, the video in the YUV color space is first converted into the video in the RGB color space, and then after step **1042**, the video in the RGB color space is reconverted into the video in the YUV color space.

YUV (also referred to as YCbCr) is a color coding method used in a European television system. In a modern color television system, a three-tube color camera or a color CCD camera is usually used for image shooting, and then an obtained color image signal is subject to color separation, amplification, and correction, so that an RGB signal is obtained. The RGB signal is then changed into a luminance signal Y and two color difference signals B-Y (U) and R-Y (V) by using a matrix conversion circuit. Finally, a transmit end encodes the three signals respectively and then transmits encoded signals through a same channel. This color representation method is the YUV color space. YCbCr is a specific implementation of a YUV model and is actually a scaled and shifted copy of YUV. Y has a same meaning as Y in YUV, and Cb and Cr both mean colors, except that Cb and Cr differ in a representation method. In a YUV family, YCbCr is a most widely used member in a computer system and is used in a wide application field, such as JPEG and MPEG. Generally, YUV mostly means YCbCr. A UV plane is shown in FIG. 8.

Interconversion of the RGB color space and the YUV color space may be implemented by a matrix of 3×3:

$$\begin{pmatrix} Y \\ U \\ V \end{pmatrix} = M_{rgb2yuv} \begin{pmatrix} R \\ G \\ B \end{pmatrix}, \begin{pmatrix} R \\ G \\ B \end{pmatrix} = M_{yuv2rgb} \begin{pmatrix} Y \\ U \\ V \end{pmatrix}$$

YUV has four main sampling formats: YCbCr 4:2:0, YCbCr 4:2:2, YCbCr 4:1:1, and YCbCr 4:4:4.

In a possible implementation, as shown in FIG. 9, an electronic device may specifically include a camera **193**, demosaic (Demosaic) modules **21**, warp modules **22**, a fusion module **23**, noise processing modules **24**, color correction matrix (Color Correction Matrix, CCM) modules **25**, global tone mapping (Global Tone Mapping, GTM)

## 12

modules **26**, scaling (Scaler) modules **27**, YUV denoising modules **28**, and LUT-based processing modules **29**. For example, during video recording, the camera **193** obtains a video image of a long exposure frame and a video image of a short exposure frame by shooting when a capture frame rate of a video shot through the camera **193** is a second frame rate. An exposure time corresponding to the video image of a long exposure frame is greater than an exposure time corresponding to the video image of a short exposure frame.

The video image of a long exposure frame and the video image of a short exposure frame are processed by the demosaic modules **21** respectively. This enables the images to be converted from a RAW domain to an RGB domain. Then the two video images are processed by the warp (warp) modules **22** respectively, so that alignment and stabilization effects are achieved by warping the video images. Then the two video images are processed by the fusion module **23**, so that the two video images are fused as one video image, and fused data is divided into two data streams. A video processing method includes a first video processing procedure S1 and a second video processing procedure S2. One of the two data streams processed by the fusion module **23** enters the first video processing procedure S1 and the other of the two data streams enters the second video processing procedure S2.

In the first video processing procedure S1, a process of step **103**: processing, by using a logarithm LOG curve, the video shot through the camera, to obtain a LOG video, and a process of step **104**: processing the LOG video based on a LUT corresponding to the determined video style template, to obtain a video corresponding to the determined video style template are performed.

For example, the first video processing procedure S1 includes: The noise processing module **24** denoises a video that is from the fusion module **23** and that is shot through the camera **193**, the CCM module **25** processes a denoised video to be converted into a video in wide-gamut RGB color space, the GTM modules **26** performs step **103** to process a converted video by using a LOG curve to obtain a LOG video, the scaling module **27** scales the video, the YUV denoising module **28** performs step **106** to perform YUV denoising on the video, and then the LUT-based processing module **29** performs step **1042** to process a video obtained by YUV denoising by using the 3D-LUT, to obtain the video corresponding to the determined video style module. After the first video processing procedure S1, the video corresponding to the determined video style template in the first video processing procedure S1 is stored as the video 1. In other words, a video with a style may be obtained.

The second video processing procedure S2 includes: The noise processing module **24** denoises a video that is from the fusion module **23** and that is shot through the camera **193**, the CCM module **25** processes a denoised video to be converted into a video in wide-gamut RGB color space, the GTM module **26** performs step **103** to process a converted video by using a LOG curve to obtain a LOG video, the scaling module **27** scales the video, the YUV denoising module **28** performs step **106** to perform YUV denoising on the video, and then the LUT-based processing module **29** performs step **1042** to process a video obtained by YUV denoising by using the 3D-LUT, to obtain the video corresponding to the determined video style module. The video corresponding to the determined video style template in the second video processing procedure S2 is previewed.

That is, during video recording, two video streams are respectively processed in the first video processing procedure S1 and the second video processing procedure S2. Two

same algorithms are respectively used in the two video streams. The two procedures each include processing based on the LOG curve in step **103** and processing based on the 3D-LUT in step **1042**. One video stream is used for encoding and storage, and the other video stream is used for preview.

The following describes relevant content of the RAW and YUV.

**Bayer domain:** Each lens on a digital camera is provided with an optical sensor to measure luminance of light. However, to obtain a full-color image, three optical sensors are usually required to obtain information on three primary colors, red, green, and blue, respectively. To reduce costs and a volume of the digital camera, a manufacturer usually uses a CCD image sensor or CMOS image sensor. Usually, a raw image output by the CMOS image sensor is in RGB format of the Bayer domain, and a single pixel includes only one color value. To obtain a gray value of an image, color information of each pixel is to be inserted and supplemented, and then a gray value of each pixel is to be calculated. In other words, the Bayer domain means a raw image format in the digital camera.

The RAW domain, alternatively referred to as a RAW format, means an unprocessed image. Further, the RAW image may be understood as raw data of a digital signal into which a photosensitive element of a camera, such as a complementary metal oxide semiconductor (Complementary Metal Oxide Semiconductor, CMOS) or a charge-coupled device (Charge-coupled Device, CCD), converts a captured light source signal. A RAW file is a file in which raw information of a sensor of the digital camera is recorded, and setting of some metadata (Metadata, such as photosensitivity ISO (International Organization for Standardization), a shutter speed, an aperture value, and a white balance) generated due to shooting by the camera is recorded. The RAW domain is a format without non-linear processing and compression by the ISP. A full name of the RAW format is a RAW image format.

**YUV** is a color encoding method and is usually used in various video processing components. When encoding a picture or a video, in consideration of human perceptibility, YUV allows a bandwidth of chrominance to be reduced. YUV is a kind of compiled true-color space (color space), and proprietary terms such as Y'UV, YUV, YCbCr, and YPbPr may all be referred to as YUV, and overlap each other. "Y" represents luminance (Luminance or Luma), that is, a grayscale value. "U" and "V" represent chrominance (Chrominance or Chroma), and are used for describing a color and saturation of a video and specifying a color of a pixel. Generally, YUV is divided into two formats. One of the two formats is a packed format (packed format) in which Y, U, V are stored as a macro pixel array in a manner similar to a manner in which RGB is stored. The other of the two formats is a planar format (planar format) in which three components of Y, U, and V are stored in different matrices respectively. The planar format (planar format) means that every Y component, U component, and V component are organized in separate planes, that is, all U components are behind the Y component, and the V component is behind all U components.

In a possible implementation, as shown in FIG. 9, before a process of step **1042**: processing the LOG video based on a 3D-LUT corresponding to the determined video style template, to obtain a video corresponding to the determined video style template, the method further includes: storing the LOG video, namely, storing a video 2. That is, after the LOG video is obtained in step **103**, one stream of the LOG video is divided and directly stored, that is, a LOG video without

a style is stored, referred to as the video 2, and the other stream of the LOG video is stored after being processed based on the 3D-LUT in step **1042**, that is, a video corresponding to a video style template is stored, referred to as a video 1. For example, during recording, two video files are encoded and stored in a temporary folder simultaneously, and one of the video files is determined as a final video file based on a user selection. If the user wants to directly record and generate a video file with a style of a movie "B", the video 1 is used as the final video file. If the user wants to store a raw material, to improve a capability of subsequent editing, the video 2 is used as the final video file. It should be noted that a process of storing a stream of the LOG video may be performed after a process in which the scaling module **27** scales a video and before a process in which the LUT-based processing module **29** performs step **104**.

In a possible implementation, as shown in FIG. 9, before a process of step **1042**: processing the LOG video based on a 3D-LUT corresponding to the determined video style template, to obtain a video corresponding to the determined video style template, the method further includes: converting the LOG video into a video with a Rec.709 color standard; and storing the video with the Rec.709 color standard, namely, the video 2. That is, after the LOG video is obtained in step **103**, one stream of the LOG video is converted into a video with a raw color, and the video with a raw color is stored as the video 2. No color grading is performed on the video. The other stream of the LOG video is stored based on 3D-LUT processing in step **1042**. That is, a video with a corresponding video style template is stored, referred to as the video 1. For example, during recording, two video files are encoded and stored in a temporary folder simultaneously, and one of the video files is determined as a final video file based on a user selection. If the user wants to directly record and generate a video file with a style of movie "B", the video with a corresponding video style template, namely, the video 1, is used as the final video file. If the user wants to store a video without color grading, a LOG video without color grading is converted into a standard video file, and the standard video file, namely, the video 2, is used as the final video file. It should be noted that a process of dividing a video into streams without color grading may be performed after a process in which the scaling module **27** scales a video and before a process in which the LUT-based processing module **29** performs step **1042**.

In a possible implementation, as shown in FIG. 10, when a capture frame rate of a video shot through a camera **193** is a first frame rate, a video corresponding to a determined video style template is divided into two streams. One stream is stored, and the other stream is previewed. The electronic device further includes a 2D-LUT-based processing module **30** in addition to the camera **193**, the demosaic modules **21**, the warp modules **22**, the fusion module **23**, the noise processing module **24**, the CCM module **25**, the GTM module **26**, and the scaling module **27**. The 2D-LUT-based processing module **30** may be a hardware module in an ISP, and the LUT-based processing module **29** may be a software module. For example, during video recording, the camera **193** obtains a video image of a long exposure frame and a video image of a short exposure frame by shooting when a capture frame rate of a video shot through the camera **193** is a second frame rate. An exposure time corresponding to the video image of a long exposure frame is greater than an exposure time corresponding to the video image of a short exposure frame. The video image of a long exposure frame and the video image of a short exposure frame are processed

15

by the demosaic modules **21** respectively. This enables the images to be converted from a RAW domain to an RGB domain. Then the two video images are processed by the warp (warp) modules **22** respectively, so that alignment and stabilization effects are achieved by warping the video images. Then the two video images are processed by the fusion module **23**, so that the two video images are fused as one video image. The fused video image is denoised by the noise processing module **24** and then processed by the CCM module **25**, to convert the video into a video in wide-gamut RGB color space. The GTM module **26** performs step **103** to process the video by using a LOG curve, to obtain the LOG video. The 2D-LUT-based processing module **30** performs step **1041**: processing the LOG video based on a 2D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a first frame rate, to obtain a video corresponding to the determined video style template. The scaling module **27** scales the video. A processed video is divided into two streams. One stream is stored, and the other stream is previewed. Based on comparison of FIG. 9 and FIG. 10, it may be learned that when the capture frame rate of the video shot through the camera **193** is a first frame rate, because the capture frame rate is low, the video may be processed by using a 3D-LUT with a more complex algorithm, to implement better color control. In addition, the two video streams may be respectively processed in modules. One of the two video streams is stored, and the other of the two streams is previewed, to enable a preview image to present a better effect and be approximately the stored video. When the capture frame rate of the video shot through the camera **193** is a second frame rate, because the capture frame rate is high, to ensure that video processing may be completed at a high frame rate, the video may be processed by using a 2D-LUT with a simple algorithm. In addition, only one video stream is used for processing in each module. After processing, one video is divided into two streams. One stream is stored, and the other stream is previewed.

Embodiments of this application are described below with reference to a software architecture. In an embodiment of this application, an Android system of a layered architecture is used as an example to describe a software structure of the electronic device **100**. FIG. 11 is a block diagram of the software structure of the electronic device **100** according to an embodiment of this application.

Software is divided into several layers by using the layered architecture, and each layer has a definite role and task. The layers communicate with each other by using a software interface. In some embodiments, an Android system is divided into five layers: an application (Application) layer, an application framework (framework) layer, a system library (library), a hardware abstraction layer (Hardware Abstraction Layer, HAL) layer, and a kernel layer from top to bottom.

The application layer may include applications such as a camera.

The application framework layer may include a camera application programming interface (Application Programming Interface, API), MediaRecorder, Surfaceview, and the like. MediaRecorder is configured to record video or picture data and to enable such data accessible to an application. Surfaceview is configured to display a previewed image.

The system library may include a plurality of functional modules, for example, CameraService.

The hardware abstraction layer is configured to provide interface support, including, for example, a camera procedure CameraPipeline to be called by a camera service.

16

The kernel layer is a layer between hardware and software. The kernel layer includes a display driver, a camera driver, and the like.

With reference to a specific scene in which a video is captured, the HAL reports capability information of recording two videos simultaneously, and the application layer sends a capturerequest (CaptureRequest) to request a stream corresponding to the video 1, a stream corresponding to the video 2, and a preview stream, and creates two mediacodec (mediacodec) examples simultaneously to receive encoding of two video streams. The HAL calls back three streams based on the dataflow (dataflow). The preview stream is sent for display, and two video streams are sent to the mediacodec respectively.

The recorded video processing method provided in embodiments of this application may be represented by a plurality of functions in two shooting modes. The two shooting modes may mean a movie mode and a professional mode.

The movie mode is a shooting mode related to a movie theme. In this mode, an image displayed by an electronic device wo may present an effect of viewing a movie to the user from senses. The electronic device wo further provides a plurality of video style templates related to the movie theme. The user may use the video style templates to obtain a tone-adjusted image or video. Tones of the images or videos are similar to or the same as tones of a movie. In the following embodiments of this application, in the movie mode, at least an interface for the user to trigger a LUT function and an HDR10 function may be provided. Refer to the following embodiment for description of the LUT function and the HDR10 function in detail.

For example, it is assumed that the electronic device **100** is a mobile phone. In a possible implementation, as shown in FIG. 3, the electronic device may display a movie mode in response to an operation of a user. For example, the electronic device **100** may detect a touch operation performed by the user on a camera application. In response to the operation, the electronic device **100** displays a default shooting interface of the camera application. The default shooting interface may include: a preview box, a shooting mode list, a gallery shortcut key, a shutter control, and the like.

The preview box may be used to display an image captured by a camera **193** in real time. The electronic device **100** may refresh display content in the preview box in real time, so that the user previews an image currently captured by the camera **193**.

One or more shooting mode options may be displayed in the shooting mode list. The one or more shooting mode options may include: a portrait mode option, a video mode option, a photo mode option, a movie mode option, and a professional option. The one or more shooting mode options may be expressed as text information on an interface, such as "PORTRAIT", "VIDEO", "PHOTO", "MOVIE", and "PRO". This application is not limited thereto. The one or more shooting mode options may be alternatively displayed as icons or interactive elements (interactive element, IE) in other forms on the interface.

The gallery shortcut may be used for starting a gallery application. The gallery application is an application for picture management on an electronic device such as a smartphone or a tablet computer, and may also be referred to as an "album". A name of the application is not limited in this embodiment. The gallery application may support the user in performing various operations on a picture stored in

the electronic device **100**, for example, operations such as browsing, editing, deleting, and selecting.

The shutter control may be configured to monitor an operation performed by the user to trigger shooting. The electronic device **100** may detect a user operation acting on the shutter control. In response to the operation, the electronic device **100** may store an image in the preview box as a picture in the gallery application. In addition, the electronic device **100** may further display a thumbnail of a stored image in the gallery shortcut. That is, the user may tap the shutter control to trigger image shooting. The shutter control may be a button or a control in another form.

The electronic device **100** may detect a touch operation by a user acting on the movie mode option. In response to the operation, the electronic device displays a user interface shown in FIG. 3.

In some embodiments, the electronic device **100** may start the movie mode by default after the camera application is started. This application is not limited thereto. The electronic device **100** may alternatively start the movie mode in another manner. For example, the electronic device **100** may alternatively start the movie mode based on a voice instruction of a user, which is not limited in this embodiment of this application.

The electronic device **100** may detect a touch operation by a user acting on the movie mode option. In response to the operation, the electronic device displays a user interface shown in FIG. 3.

The user interface shown in FIG. 3 includes functional options including an HDR10 option, a flash option, a LUT option, and a setting option. The plurality of functional options may detect a touch operation of the user. In response to the operation, a corresponding shooting function is enabled or disabled, such as an HDR10 function, a flash function, a LUT function, and a setting function.

The electronic device may enable the LUT function. The LUT function may change a display effect of a previewed image. Actually, a look up table is introduced in the LUT function. The look up table is equivalent to a color conversion model capable of outputting an adjusted color value based on an input color value. A color value of an image captured by a camera is equivalent to an input value. After different color values pass through the color conversion model, output values can be obtained correspondingly. Finally, an image displayed in the preview box is an image adjusted by the color conversion model. The electronic device **100** uses the LUT function to display an image including color values adjusted by the color conversion model, to achieve an effect of adjusting an image tone. After the LUT function is enabled, the electronic device **100** may provide a plurality of video style templates. One video style template is corresponding to one color conversion model, and different video style templates may bring different display effects to a previewed image. In addition, the video style templates may be associated with the movie theme. The video style templates may provide the previewed image with an adjusted tone that is similar to or the same as a tone in a movie, creating an atmosphere for the user in which a movie is shot.

In addition, after the electronic device **100** enables the LUT function, the electronic device **100** may determine one video style template among a plurality of video style templates based on a currently previewed video image. The determined video style template may be displayed in an interface, so that the user may understand the currently determined video style template. For example, the plurality of video style templates include a style template of a movie

"A", a style template of a movie "B", and a style template of a movie "C". LUTs corresponding to different style templates of movies may be generated in advance based on corresponding color matching styles of movies. Color conversion of the LUT has a style characteristic corresponding to a movie. A LUT appropriate for a mobile electronic device may be generated by pre-extraction from the movie style. Enabling the LUT function changes a tone of the previewed video image. As illustrated in FIG. 3, the electronic device **100** determines and displays the style template of the movie "A".

In some embodiments, the electronic device **100** may select a video style template based on a sliding operation of a user. Specifically, after the electronic device **100** detects a user operation of the user to enable the LUT function and displays a LUT preview window, the electronic device **100** may select a first video style template in the LUT preview window by default as a video style template selected by the electronic device **100**. Then the electronic device **100** may detect a left-right sliding operation of the user acting on the LUT preview window and move a position of each video style template in the LUT preview window. When the electronic device **100** no longer detects the sliding operation of the user, the electronic device **100** uses the first video style template displayed in the LUT preview window as the video style template selected by the electronic device **100**.

In some embodiments, in addition to changing a display effect of a previewed image by using a video style template, the electronic device **100** may detect a user operation of starting to record a video after the video style template is detected. In response to the operation, the electronic device **100** starts to record a video, to obtain a video with a display effect adjusted by using the video style template. In addition, during video recording, the electronic device **100** may also detect a user operation of shooting a photo. In response to the operation, the electronic device **100** stores, as a picture, a previewed image to which a video style template is added in the preview box, to obtain an image with a display effect adjusted by using the video style template.

The electronic device may enable the HDR10 function. In the HDR10 mode, HDR is a high-dynamic range (High-Dynamic Range, HDR). Compared with a normal image, HDR can provide more dynamic ranges and image details, and can better reflect a visual effect in a real environment. 10 in HDR10 is 10 bits, and HDR10 can record a video in a high dynamic range of 10 bits.

The electronic device **100** may detect a touch operation of the user acting on the professional mode option, to display the professional mode. As shown in FIG. 12, when the electronic device is in the professional mode, functional options that may be included in a user interface are, for example, a LOG option, a flash option, a LUT option, and a setting option. In addition, the user interface further includes a parameter adjustment option, for example, a photometric M option, an ISO option, a shutter S option, an exposure value EV option, a focusing manner AF option, and a white balance WB option.

In some embodiments, the electronic device **100** may start the professional mode by default after the camera application is started. This application is not limited thereto. The electronic device **100** may alternatively start the professional mode in another manner. For example, the electronic device **100** may alternatively start the professional mode based on a voice instruction of a user, which is not limited in this embodiment of this application.

The electronic device **100** may detect a user operation of the user acting on the LOG option. In response to the

operation, the electronic device **100** enables the LOG function. The LOG function can apply a logarithmic function to an exposure curve, to keep details of a highlight and shadow of an image captured by a camera to the maximum extent, so that a finally presented previewed image has a low saturation. A video recorded by using the LOG function is referred to as a LOG video.

In the professional mode, the electronic device **100** may record a video to which a video style template is added, may alternatively add a video style template to a video to which no video style template is added, or record a LOG video after enabling the LOG function, and then add a video style template to the LOG video. In this way, the electronic device **100** may not only adjust a display effect of an image before recording a video, but also adjust a display effect of a recorded video after completing video recording, increasing flexibility and freedom of image adjustment.

An embodiment of this application further provides a video processing apparatus. The apparatus includes: a video style determining module, configured to determine one video style template among a plurality of video style templates, where each video style template is corresponding to a preset three-dimensional look up table LUT; a video obtaining module, configured to obtain a video shot through a camera; a first processing module, configured to process a video shot through the camera by using a logarithm LOG curve corresponding to a current photosensitivity ISO of the camera, to obtain a LOG video; and a second processing module, configured to process the LOG video based on a 2D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a first frame rate, to obtain a video corresponding to the determined video style template; and a third processing module, configured to process the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the determined video style template. The first frame rate is greater than the second frame rate.

The foregoing video processing method may be applied to the video processing apparatus. A specific process and principle are not described herein again. The first processing module may be specifically the GTM module **26** in the foregoing embodiment, the second processing module may be specifically the 2D-LUT-based processing module **30** in the foregoing embodiment, and the third processing module may be specifically the LUT-based processing module **29** in the foregoing embodiment.

In a possible implementation, the third processing module is specifically configured to: establish cube interpolation space based on a LUT, where the LUT is a 3D-LUT; determine a cube to which each pixel in the LOG video belongs in the cube interpolation space, where the cube is divided into six tetrahedrons; determine a tetrahedron to which each pixel in the LOG video belongs; convert a pixel value of a pixel corresponding to a vertex of a cube into a pixel value obtained by LUT processing; and perform interpolation, based on the tetrahedron to which each pixel belongs, on a pixel not corresponding to the vertex of the cube, and converting the pixel value into a pixel value obtained by LUT processing.

In a possible implementation, the second processing module is specifically configured to process the LOG video based on a 3D-LUT corresponding to the determined video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video

corresponding to the determined video style template. The first frame rate is greater than the second frame rate.

In a possible implementation, the video processing apparatus further includes a video stream dividing and processing module, configured to divide a video corresponding to a determined video style template into two streams when a capture frame rate of a video shot through a camera is a first frame rate. One stream is stored, and the other stream is previewed.

In a possible implementation, the first frame rate is 120 frames per second FPS or 60 FPS, and the second frame rate is 30 FPS.

In a possible implementation, the video processing apparatus further includes: a conversion module, configured to convert the LOG video from a LOG video in RGB color space to a LOG video in YUV color space, where the conversion module may be specifically located between the scaling module **27** and the YUV denoising module **28** in FIG. **9**, and the conversion module is not shown in FIG. **9**; and a YUV denoising module **28**, configured to perform YUV denoising on the LOG video in the YUV color space, to obtain a denoised LOG video.

In a possible implementation, the video processing apparatus further includes: a first conversion module, configured to convert the denoised LOG video from the LOG video in the YUV color space to the LOG video in the RGB color space, where the first conversion module may be located between the YUV denoising module **28** and the LUT-based processing module **29** in FIG. **9**; and a second conversion module, configured to convert a video that is in the RGB color space and that is corresponding to the determined video style template into a video in the YUV color space, where the second conversion module may be located between the LUT-based processing module **29** and a process of storing the video **1** in FIG. **9**. The first conversion module and the second conversion module are not shown in FIG. **9**.

In a possible implementation, the video processing apparatus further includes: a first storing module, configured to store a video corresponding to the determined video style template; and a second storing module, configured to store the LOG video.

In a possible implementation, the video processing apparatus further includes: a first storing module, configured to store a video corresponding to the determined video style template; a backup and conversion module, configured to convert the LOG video into a video with a Rec.709 color standard; and a second storing module, configured to store the video with the Rec.709 color standard.

In a possible implementation, in a first video processing procedure, a process of processing, by using a logarithm LOG curve, the video shot through the camera, to obtain a LOG video, and a process of processing the LOG video based on a LUT corresponding to the determined video style template, to obtain a video corresponding to the determined video style template are performed. The video processing method further includes a second video processing procedure. The second video processing procedure includes: a process of processing, by using a logarithm LOG curve, the video shot through the camera, to obtain a LOG video; and a process of processing the LOG video based on a LUT corresponding to the determined video style template, to obtain a video corresponding to the determined video style template. The video processing method further includes: a first storing module, configured to store the video corresponding to the determined video style template in the first video processing procedure; and a preview module, config-

ured to preview the video corresponding to the determined video style template in the second video processing procedure.

In a possible implementation, a cube has a 0<sup>th</sup> vertex to a 7<sup>th</sup> vertex. A direction from the 0<sup>th</sup> vertex to a 1<sup>st</sup> vertex is a coordinate axis direction of a blue B channel. A direction from the 0<sup>th</sup> vertex to a 4<sup>th</sup> vertex is a coordinate axis direction of a red R channel. A direction from the 0<sup>th</sup> vertex to a 2<sup>nd</sup> vertex is a coordinate axis direction of a green G channel. The 0<sup>th</sup> vertex, the 1<sup>st</sup> vertex, the 2<sup>nd</sup> vertex, and a 3<sup>rd</sup> vertex are located in a same plane. The 1<sup>st</sup> vertex, the 3<sup>rd</sup> vertex, a 5<sup>th</sup> vertex, and the 7<sup>th</sup> vertex are located in a same plane. The 4<sup>th</sup> vertex, the 5<sup>th</sup> vertex, a 6<sup>th</sup> vertex, and the 7<sup>th</sup> vertex are located in a same plane. The 0<sup>th</sup> vertex, the 2<sup>nd</sup> vertex, the 4<sup>th</sup> vertex, and the 6<sup>th</sup> vertex are located in a same plane. The 0<sup>th</sup> vertex, the 1<sup>st</sup> vertex, the 5<sup>th</sup> vertex, and the 7<sup>th</sup> vertex form a first tetrahedron. The 0<sup>th</sup> vertex, the 1<sup>st</sup> vertex, the 3<sup>rd</sup> vertex, and the 7<sup>th</sup> vertex form a second tetrahedron. The 0<sup>th</sup> vertex, the 2<sup>nd</sup> vertex, the 3<sup>rd</sup> vertex, and the 7<sup>th</sup> vertex form a third tetrahedron. The 0<sup>th</sup> vertex, the 4<sup>th</sup> vertex, the 5<sup>th</sup> vertex, and the 7<sup>th</sup> vertex form a fourth tetrahedron. The 0<sup>th</sup> vertex, the 4<sup>th</sup> vertex, the 6<sup>th</sup> vertex, and the 7<sup>th</sup> vertex form a fifth tetrahedron. The 0<sup>th</sup> vertex, the 2<sup>nd</sup> vertex, the 6<sup>th</sup> vertex, and the 7<sup>th</sup> vertex form a sixth tetrahedron. The first processing module is specifically configured to generate a pixel value VE (R, G, B) of a E channel obtained by LUT processing based on a current pixel (R, G, B), where E is R, G, and B respectively.  $VE(R, G, B) = VE(R0, G0, B0) + (\Delta R \times \Delta R + \Delta G \times \Delta G + \Delta B \times \Delta B + (\text{step\_size} \gg 1)) / (\text{step\_size})$ . VE (R0, G0, B0) is a pixel value of a E channel obtained by LUT processing at the 0<sup>th</sup> vertex (R0, G0, B0), where E is R, G, and B respectively.  $\Delta R$  is a difference between pixel values of the R channel that are obtained by LUT processing and that are of two vertices in the coordinate axis direction of the R channel corresponding to the tetrahedron to which the current pixel belongs.  $\Delta G$  is a difference between pixel values of the G channel that are obtained by LUT processing and that are of two vertices in the coordinate axis direction of the G channel corresponding to the tetrahedron to which the current pixel belongs.  $\Delta B$  is a difference between pixel values of the B channel that are obtained by LUT processing and that are of two vertices in the coordinate axis direction of the B channel corresponding to the tetrahedron to which the current pixel belongs.  $\Delta R$  is a difference between an R value in the current pixel (R, G, B) and an R0 value at the 0<sup>th</sup> vertex (R0, G0, B0),  $\Delta G$  is a difference between a G value in the current pixel (R, G, B) and a G0 value at the 0<sup>th</sup> vertex (R0, G0, B0), and  $\Delta B$  is a difference between a B value in the current pixel (R, G, B) and a B0 value at the 0<sup>th</sup> vertex (R0, G0, B0).  $\text{step\_size}$  is a side length of the cube.

It should be understood that division of the video processing apparatus into modules is merely logical function division. The modules may be all or partially integrated into a physical entity or may be physically separated in actual implementation. In addition, all of the modules may be implemented in a form of software invoked by using a processing element or may be implemented in a form of hardware. Alternatively, some modules may be implemented in a form of software invoked by using the processing element, and some modules are implemented in a form of hardware. For example, any one of the video style determining module, the video obtaining module, the first processing module, the second processing module, and the third processing module may be an independent processing element, or may be integrated into the video processing appa-

ratus, for example, integrated into a chip of the video processing apparatus, or may be stored in a memory of the video processing apparatus in a form of a program. Functions of the foregoing modules may be called and performed by a processing element of the video processing apparatus. Implementations of other modules are similar thereto. In addition, all or some of these modules may be integrated together or implemented independently. The processing element herein may be an integrated circuit having a signal processing capability. During implementation, steps of the foregoing method or the foregoing modules may be completed through an integrated logic circuit of the hardware in the processor element or an instruction in the form of software.

For example, the modules including the video style determining module, the video obtaining module, the first processing module, the second processing module, and the third processing module may be one or more integrated circuits configured to implement the foregoing method, such as one or more application-specific integrated circuits (Application-Specific Integrated Circuit, ASIC), one or more microprocessors (digital signal processor, DSP), or one or more field programmable gate arrays (Field Programmable Gate Array, FPGA). For another example, when one of the foregoing modules is implemented in a form of a program invoked by the processing component, the processing component may be a general processor, for example, a central processing unit (Central Processing Unit, CPU) or another processor that may invoke the program. For another example, the modules may be integrated in a form of a system-on-a-chip (system-on-a-chip, SOC) for implementation.

An embodiment of this application further provides a video processing apparatus. The video processing apparatus includes: a processor and a memory. The memory is configured to store at least one instruction. The instruction is loaded and executed by the processor to implement the video processing method in any one of the foregoing embodiments.

The foregoing video processing method may be applied to the video processing apparatus. A specific process and principle are not described herein again.

A quantity of processors may be one or more. The processor and memory may be connected via a bus in another manner. The memory, as a non-transitory computer-readable storage medium, may be configured to store a non-transitory software program, a non-transitory computer-executable program, and a module, such as program instructions/module corresponding to the video processing apparatus in this embodiment of this application. The processor runs the non-transitory software program, instructions, and the module that are stored in the memory, to execute various functional applications and data processing, that is, implement a method in any one of the foregoing method embodiments. The memory may include a program storage area and a data storage area. The program storage area may store an operating system, an application required for at least one function, necessary data, and the like. In addition, the memory may include a high speed random access memory, and may also include a non-transient memory, such as at least one magnetic disk storage device, a flash memory, or another non-transient solid state storage device.

As shown in FIG. 1, an embodiment of this application further provides an electronic device. The electronic device includes a camera 193 and the foregoing video processing apparatus. The video processing apparatus includes a processor no.

23

A specific principle and working process of the video processing apparatus are the same as a specific principle and working process in foregoing embodiments. The details are not described herein again. The electronic device may be any product or component having a video shooting function, such as a mobile phone, a television, a tablet computer, a watch, a wristband, or the like.

An embodiment of this application further provides a computer-readable storage medium. The computer-readable storage medium stores a computer program. When the computer program is run on a computer, the computer is enabled to perform the video processing method in any one of the foregoing embodiments.

In the foregoing embodiments, all or some of the foregoing embodiments may be implemented by using software, hardware, firmware, or any combination thereof. When the software is used for implementing the embodiments, all or a part of the embodiments may be implemented in a form of a computer program product. The computer program product includes one or more computer instructions. When the computer program instructions are loaded and executed on a computer, the procedure or functions according to this application are all or partially generated. The computer may be a general-purpose computer, a dedicated computer, a computer network, or another programmable apparatus. The computer instructions may be stored in a computer-readable storage medium or may be transmitted from a computer-readable storage medium to another computer-readable storage medium. For example, the computer instructions may be transmitted from a website, computer, server, or data center to another website, computer, server, or data center in a wired (for example, a coaxial cable, an optical fiber, or a digital subscriber line) or wireless (for example, infrared, radio, or microwave) manner. The computer-readable storage medium may be any usable medium accessible by the computer, or a data storage device, for example, a server or a data center, integrating one or more usable media. The usable medium may be a magnetic medium (for example, a floppy disk, a hard disk, or a magnetic tape), an optical medium (for example, a DVD), a semiconductor medium (for example, a solid state disk (Solid State Disk)), or the like.

In embodiments of this application, “at least one” means one or more, and “a plurality” means two or more. A term “and/or” describes an association relationship between associated objects and indicates that three relationships may exist. For example, A and/or B may indicate the following three cases: Only A exists, both A and B exist, and only B exists, where A and B may be singular or plural. The character “/” generally indicates an “or” relationship between associated objects before and after the character. “at least one of the following” or a similar expression thereof means any combination of these items, including a single item or any combination of a plurality of items. For example, at least one of a, b, and c may represent a, b, c, a and b, a and c, b and c, or a, b, and c. a, b, and c may be single or multiple.

The foregoing descriptions are merely exemplary embodiments of this application, but are not intended to limit this application. Persons skilled in the art understand that this application may have various modifications and variations. Any modification, equivalent replacement, and improvement made without departing from the spirit and principle of this application shall fall within the protection scope of this application.

24

What is claimed is:

1. A video processing method, comprising:

determining a first video style template among a plurality of video style templates, wherein each video style template corresponds to a preset look up table (LUT); obtaining a video shot through a camera;

processing the video shot through the camera by using a logarithm (LOG) curve corresponding to a current photosensitivity ISO of the camera, to obtain a LOG video; and

processing the LOG video based on a 2D-LUT corresponding to the first video style template when a capture frame rate of the video shot through the camera is a first frame rate, to obtain a video corresponding to the first video style template; and

processing the LOG video based on a 3D-LUT corresponding to the first video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the first video style template, wherein the first frame rate is greater than the second frame rate, the processing the LOG video based on the 3D-LUT corresponding to the first video style template comprising:

establishing cube interpolation space based on the 3D-LUT;

determining a cube to which at least one pixel in the LOG video belongs in the cube interpolation space, wherein the cube is divided into six tetrahedrons; determining a tetrahedron to which the at least one pixel in the LOG video belongs;

converting a pixel value of a pixel corresponding to a vertex of the cube into a pixel value processed by using the 3D-LUT; and

performing interpolation, based on the tetrahedron to which the at least one pixel belongs, on a pixel not corresponding to the vertex of the cube, and converting the pixel value into a pixel value obtained by 3D-LUT processing.

2. The video processing method according to claim 1, wherein

processing the LOG video based on the 2D-LUT corresponding to the first video style template when the capture frame rate of the video shot through the camera is a first frame rate, to obtain the video corresponding to the first video style template is performed in HSV color space.

3. The video processing method according to claim 1, wherein

before processing the LOG video based on the 3D-LUT corresponding to the first video style template when the capture frame rate of the video shot through the camera is the second frame rate, to obtain the video corresponding to the first video style template, the method further comprises:

converting the LOG video from a LOG video in RGB color space to a LOG video in YUV color space; and performing YUV denoising on the LOG video in the YUV color space, to obtain a denoised LOG video.

4. The video processing method according to claim 3, wherein

before processing the LOG video based on the 3D-LUT corresponding to the first video style template when the capture frame rate of the video shot through the camera is the second frame rate, to obtain the video corresponding to the first video style template, the method further comprises:

25

converting the denoised LOG video from a LOG video in the YUV color space to a LOG video in the RGB color space; and  
 after processing the LOG video based on the LUT corresponding to the first video style template, to obtain the video corresponding to the first video style template, the method further comprises:  
 converting a video that is in the RGB color space and that is corresponding to the determined video style template into a video in the YUV color space.

5 The video processing method according to claim 1, further comprising:  
 dividing the video corresponding to the first video style template into two streams when the capture frame rate of the video shot through the camera is the first frame rate, wherein one stream is stored, and the other stream is previewed.

15 The video processing method according to claim 1, wherein the first frame rate is 120 frames per second (FPS) or 60 FPS, and the second frame rate is 30 FPS.

20 The video processing method according to claim 1, wherein the LOG video is processed based on the 3D-LUT corresponding to the first video style template.

25 An electronic device, comprising:  
 a camera, a processor and a memory, wherein the memory is configured to store at least one instruction, and when the instruction is loaded and executed by the processor, the electronic device is caused to perform operations comprising:  
 determining a first video style template among a plurality of video style templates, wherein each video style template corresponds to a preset look up table (LUT);  
 obtaining a video shot through the camera;  
 processing the video shot through the camera by using a logarithm (LOG) curve corresponding to a current photosensitivity ISO of the camera, to obtain a LOG video; and  
 processing the LOG video based on a 2D-LUT corresponding to the first video style template when a capture frame rate of the video shot through the camera is a first frame rate, to obtain a video corresponding to the first video style template; and  
 processing the LOG video based on a 3D-LUT corresponding to the first video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the first video style template, wherein the first frame rate is greater than the second frame rate, and processing the LOG video based on the 3D-LUT comprises:  
 establishing cube interpolation space based on the 3D-LUT;  
 determining a cube to which at least one pixel in the LOG video belongs in the cube interpolation space, wherein the cube is divided into six tetrahedrons;  
 determining a tetrahedron to which the at least one pixel in the LOG video belongs;  
 converting a pixel value of a pixel corresponding to a vertex of the cube into a pixel value processed by using the 3D-LUT; and  
 performing interpolation, based on the tetrahedron to which the at least one pixel belongs, on a pixel not corresponding to the vertex of the cube, and converting the pixel value into a pixel value obtained by 3D-LUT processing.

26

9. The electronic device according to claim 8, wherein processing the LOG video based on the 2D-LUT corresponding to the first video style template when a capture frame rate of the video shot through the camera is a first frame rate, to obtain a video corresponding to the first video style template is performed in HSV color space.

10. The electronic device according to claim 8, wherein before processing the LOG video based on the 3D-LUT corresponding to the first video style template when the capture frame rate of the video shot through the camera is the second frame rate, to obtain the video corresponding to the first video style template, the operations further comprise:  
 converting the LOG video from a LOG video in RGB color space to a LOG video in YUV color space; and  
 performing YUV denoising on the LOG video in the YUV color space, to obtain a denoised LOG video.

11. The electronic device according to claim 10, wherein before processing the LOG video based on the 3D-LUT corresponding to the first video style template when the capture frame rate of the video shot through the camera is the second frame rate, to obtain the video corresponding to the first video style template, the operations further comprise:  
 converting the denoised LOG video from a LOG video in the YUV color space to a LOG video in the RGB color space; and  
 after processing the LOG video based on the LUT corresponding to the first video style template, to obtain the video corresponding to the first video style template, the operations further comprise:  
 converting a video that is in the RGB color space and that correspond to the first video style template into a video in the YUV color space.

12. The electronic device according to claim 8, further comprising:  
 dividing the video corresponding to the first video style template into two streams when the capture frame rate of the video shot through the camera is the first frame rate, wherein one stream is stored, and the other stream is previewed.

13. The electronic device according to claim 8, wherein the first frame rate is 120 frames per second (FPS) and the second frame rate is 30 FPS.

14. The electronic device according to claim 8, wherein the first frame rate is 60 frames per second (FPS) and the second frame rate is 30 FPS.

15. The electronic device according to claim 8, wherein the LOG video is processed based on the 3D-LUT corresponding to the first video style template.

16. A non-transitory computer-readable storage medium, wherein the non-transitory computer-readable storage medium stores a computer program, and when the computer program is run on a computer, the computer is enabled to perform operations comprising:  
 determining a first video style template among a plurality of video style templates, wherein each video style template corresponds to a preset look up table (LUT);  
 obtaining a video shot through a camera;  
 processing the video shot through the camera by using a logarithm (LOG) curve corresponding to a current photosensitivity ISO of the camera, to obtain a LOG video; and  
 processing the LOG video based on a 2D-LUT corresponding to the first video style template when a capture frame rate of the video shot through the camera

is a first frame rate, to obtain a video corresponding to the first video style template; and  
 processing the LOG video based on a 3D-LUT corresponding to the first video style template when a capture frame rate of the video shot through the camera is a second frame rate, to obtain a video corresponding to the first video style template, wherein the first frame rate is greater than the second frame rate, wherein processing the LOG video based on the 3D-LUT comprises:  
 establishing cube interpolation space based on the 3D-LUT;  
 determining a cube to which at least one pixel in the LOG video belongs in the cube interpolation space, wherein the cube is divided into six tetrahedrons;  
 determining a tetrahedron to which the at least one pixel in the LOG video belongs;  
 converting a pixel value of a pixel corresponding to a vertex of the cube into a pixel value processed by using the 3D-LUT; and  
 performing interpolation, based on the tetrahedron to which the at least one pixel belongs, on a pixel not corresponding to the vertex of the cube, and converting the pixel value into a pixel value obtained by 3D-LUT processing.

17. The non-transitory computer-readable storage medium according to claim 16, wherein the LOG video is processed based on the 3D-LUT corresponding to the first video style template.
