HEAVY DUTY TIRE**REFERENCE TO RELATED APPLICATION**

[0001] The present application claims priority based on Japanese Patent Application No. 2024-034616 filed in Japan on Mar. 7, 2024, and entire contents of this Japanese Patent Application are incorporated herein by reference.

TECHNICAL FIELD

[0002] The present invention relates to heavy duty tires.

BACKGROUND ART

[0003] From the viewpoint of consideration for the environment and safety, reduction of rolling resistance and improvement of running performance on a wet road surface (hereinafter referred to as wet performance) are required.

[0004] For example, in PATENT LITERATURE 1, rolling resistance is reduced by providing projection portions projecting toward each other from land portions adjacent to each other with a circumferential groove therebetween, and wet performance is improved by providing an outside groove space on the radially outer side of the projection portions, providing an inside groove space on the radially inner side of the projection portions, and providing communication recesses that provide communication between both spaces.

CITATION LIST**Patent Literature**

[0005] PATENT LITERATURE 1: Japanese Laid-Open Patent Publication No. 2017-94891

SUMMARY OF THE INVENTION**Technical Problem**

[0006] An object of the present invention is to provide a heavy duty tire that can suppress a decrease in wet performance due to wear while reducing rolling resistance.

Solution to Problem

[0007] A heavy duty tire according to an aspect of the present invention includes a tread formed from a rubber composition containing a rubber component including a styrene butadiene rubber and a filler including silica. The tread has a tread surface configured to come into contact with a road surface. The tread includes a plurality of circumferential grooves continuously extending circumferentially. The plurality of circumferential grooves provides the tread with a plurality of land portions aligned axially. The plurality of land portions includes a plurality of main land portions positioned between the circumferential grooves adjacent to each other. Each of the main land portions includes a plurality of main lateral grooves connecting the circumferential grooves adjacent to each other. The plurality of main lateral grooves provides the main land portions with a plurality of main blocks aligned circumferentially. Each of the main lateral grooves includes a groove portion and a sipe portion positioned radially inside the groove portion and provided continuously to the groove portion. The sipe portion is smaller in groove width than the groove portion. The circumferential groove positioned

between the main land portions adjacent to each other is a circumferential narrow groove. In the plurality of main land portions, the main land portions positioned axially outermost are outer main land portions. The circumferential groove positioned axially outside each of the outer main land portions is a circumferential wide groove larger in groove width than the circumferential narrow groove. The circumferential narrow groove includes a body portion and an enlarged width portion positioned radially inside the body portion. The body portion includes a body portion main body provided continuously from the enlarged width portion. The tread is deformed to bring facing wall surfaces of the circumferential narrow groove into contact with each other at the body portion main body. The enlarged width portion has a maximum groove width larger than a minimum groove width of the body portion main body. Between the body portion main body and a position at which the enlarged width portion has the maximum groove width, a position at which the enlarged width portion has a groove width equal to 2.0 times the minimum groove width of the body portion main body is a width reference position. The groove portion has a groove depth MH smaller than a groove depth HB from a groove opening of the circumferential narrow groove to the width reference position. An amount CSB of the styrene butadiene rubber in 100 parts by mass of the rubber component is not less than 10 parts by mass. An amount BS of the silica per 100 parts by mass of the rubber component is not less than 15 parts by mass. The amount CSB of the styrene butadiene rubber, the amount BS of the silica, the groove depth MH (mm) of the groove portion, and the groove depth HB (mm) from the groove opening of the circumferential narrow groove to the width reference position satisfy the following relational expression.

$$(CSB + BS)/(HB - MH) \geq 5$$

Advantageous Effects of the Invention

[0008] The present invention can provide a heavy duty tire that can suppress a decrease in wet performance due to wear while reducing rolling resistance.

BRIEF DESCRIPTION OF DRAWINGS

[0009] FIG. 1 is a developed view showing a part of a tread of a heavy duty tire according to an embodiment of the present invention.

[0010] FIG. 2 is a developed view showing a part of FIG. 1.

[0011] FIG. 3 is a cross-sectional view taken along a line III-III in FIG. 1.

[0012] FIG. 4 is a cross-sectional view taken along a line IV-IV in FIG. 2.

[0013] FIG. 5 is a cross-sectional view taken along a line V-V in FIG. 2.

[0014] FIG. 6 is a cross-sectional view taken along a line VI-VI in FIG. 2.

[0015] FIG. 7 is a cross-sectional view of a transverse sipe shown in FIG. 6 according to a variation.

[0016] FIG. 8 is an explanatory cross-sectional view on disposition of a main lateral groove, a circumferential narrow groove, and a transverse sipe.

[0017] FIG. 9 is an explanatory cross-sectional view on disposition of a main lateral groove, a circumferential narrow groove, and a transverse sipe according to a variation.

[0018] FIG. 10 is an explanatory cross-sectional view on disposition of a main lateral groove, a circumferential narrow groove, and a transverse sipe according to another variation.

DETAILED DESCRIPTION

[0019] A tire of the present disclosure is fitted on a rim. The inside of the tire is filled with air to adjust the internal pressure of the tire. The tire fitted on the rim is also referred to as tire-rim assembly. The tire-rim assembly includes the rim and the tire fitted on the rim.

[0020] In the present disclosure, a state where a tire is fitted on a normal rim, the internal pressure of the tire is adjusted to a normal internal pressure, and no load is applied to the tire is referred to as a normal state.

[0021] In the present disclosure, unless otherwise specified, the dimensions and angles of each component of the tire are measured in the normal state.

[0022] The dimensions and angles of each component in a meridian cross-section of the tire, which cannot be measured in a state where the tire is fitted on the normal rim, are measured in a cut plane of the tire obtained by cutting the tire along a plane including a rotation axis. In this measurement, the tire is set such that the distance between right and left beads is equal to the distance between the beads in the tire that is fitted on the normal rim. The configuration of the tire that cannot be confirmed in a state where the tire is fitted on the normal rim is confirmed in the above-described cut plane.

[0023] The normal rim means a rim specified in a standard on which the tire is based. The “standard rim” in the JATMA standard, the “Design Rim” in the TRA standard, and the “Measuring Rim” in the ETRTO standard are normal rims.

[0024] The normal internal pressure means an internal pressure specified in the standard on which the tire is based. The “highest air pressure” in the JATMA standard, the “maximum value” recited in the “TIRE LOAD LIMITS AT VARIOUS COLD INFLATION PRESSURES” in the TRA standard, and the “INFLATION PRESSURE” in the ETRTO standard are normal internal pressures.

[0025] A normal load means a load specified in the standard on which the tire is based. The “maximum load capacity” in the JATMA standard, the “maximum value” recited in the “TIRE LOAD LIMITS AT VARIOUS COLD INFLATION PRESSURES” in the TRA standard, and the “LOAD CAPACITY” in the ETRTO standard are normal loads.

[0026] In the present disclosure, a tread portion of the tire is a portion of the tire that comes into contact with a road surface. A bead portion is a portion of the tire that is fitted to a rim. A sidewall portion is a portion of the tire that extends between the tread portion and the bead portion. The tire includes a tread portion, a pair of bead portions, and a pair of sidewall portions as portions thereof.

[0027] A center portion of the tread portion is also referred to as crown portion. A portion of the tread portion at an end thereof is also referred to as shoulder portion.

Findings Supporting the Present Disclosure

[0028] A tire has rolling resistance reduced by revising blending of a rubber composition forming a tread so as to decrease $\tan \delta$ at 70° C. However, $\tan \delta$ at 0° C. is also decreased in this case. Higher $\tan \delta$ at 0° C. is more preferred for improvement of wet performance. Revising blending of the rubber composition is difficult to achieve both reduction in rolling resistance and improvement of wet performance.

[0029] A narrow groove having wall surfaces that can support each other due to deformation of a tread can effectively suppress deformation of the tread.

[0030] Carving a circumferentially extending narrow groove (hereinafter, circumferential narrow groove) in a tread in place of a conventional circumferential main groove may achieve reduction of rolling resistance without revising blending the rubber composition. However in this case, the tread is higher in stiffness than a conventional tread and may thus be decreased in wet performance. Considered in order to suppress the decrease in wet performance is also providing a lateral groove traversing a land portion.

[0031] A tread wears. This decreases capacity of a groove carved in the tread. The decrease in groove capacity leads to a decrease in drainability. In the case where a tread is provided with a circumferential narrow groove and a lateral groove, a tire can be reduced in rolling resistance while suppressing a decrease in wet performance at an initial stage of wear. However, wet performance may be decreased at or after a middle stage of wear.

[0032] Assume that the circumferential narrow groove includes a radially inner portion provided with an enlarged width portion enlarged in groove width, the lateral groove includes a radially inner portion provided with a sipe portion, and the enlarged width portion and the sipe portion are formed to be exposed at or after the middle stage of wear. In this case, the decrease in wet performance may be suppressed at or after the middle stage of wear.

[0033] A worn tread is decreased in volume. The tread is thus increased in apparent stiffness. The increase in stiffness advantageously affects rolling resistance but disadvantageously affects wet performance. Accordingly, in a case where the sipe portion is exposed formerly and a maximum groove width position of the enlarged width portion is exposed latterly, the tire may fail to sufficiently suppress the decrease in wet performance with only the sipe portion exposed formerly.

[0034] In view of this, in order to achieve both reduction in rolling resistance and improvement of wet performance, the present inventors provide the tread with the circumferential narrow groove including the enlarged width portion and the lateral groove including the sipe portion and have focused on and considered amounts of a styrene butadiene rubber and silica contained in the rubber composition forming the tread (specifically a cap portion) and timing of exposing the enlarged width portion and a tubular portion, to complete the following invention.

Details of Embodiment of the Present Disclosure

[0035] Description is made in detail hereinafter to a preferred embodiment of the present disclosure with reference to the drawings as appropriate.

[0036] The present disclosure provides a heavy duty tire including a tread formed from a rubber composition containing a rubber component including a styrene butadiene

rubber and a filler including silica, the tread having a tread configured surface to come into contact with a road surface, in which

- [0037] the tread includes a plurality of circumferential grooves continuously extending circumferentially,
- [0038] the plurality of circumferential grooves provides the tread with a plurality of land portions aligned axially,
- [0039] the plurality of land portions includes a plurality of main land portions positioned between the circumferential grooves adjacent to each other,
- [0040] each of the main land portions includes a plurality of main lateral grooves connecting the circumferential grooves adjacent to each other,
- [0041] the plurality of main lateral grooves provides the main land portions with a plurality of main blocks aligned circumferentially,
- [0042] each of the main lateral grooves includes a groove portion and a sipe portion positioned radially inside the groove portion and provided continuously to the groove portion,
- [0043] the sipe portion is smaller in groove width than the groove portion,
- [0044] the circumferential groove positioned between the main land portions adjacent to each other is a circumferential narrow groove,
- [0045] in the plurality of main land portions, the main land portions positioned axially outermost are outer main land portions,
- [0046] the circumferential groove positioned axially outside each of the outer main land portions is a circumferential wide groove larger in groove width than the circumferential narrow groove,
- [0047] the circumferential narrow groove includes a body portion and an enlarged width portion positioned radially inside the body portion,
- [0048] the body portion includes a body portion main body provided continuously from the enlarged width portion,
- [0049] the tread is deformed to bring facing wall surfaces of the circumferential narrow groove into contact with each other at the body portion main body,
- [0050] the enlarged width portion has a maximum groove width larger than a minimum groove width of the body portion main body,
- [0051] between the body portion main body and a position at which the enlarged width portion has the maximum groove width, a position at which the enlarged width portion has a groove width equal to 2.0 times the minimum groove width of the body portion main body is a width reference position,
- [0052] the groove portion has a groove depth MH smaller than a groove depth HB from a groove opening of the circumferential narrow groove to the width reference position,
- [0053] an amount CSB of the styrene butadiene rubber in 100 parts by mass of the rubber component is not less than 10 parts by mass,
- [0054] an amount BS of the silica per 100 parts by mass of the rubber component is not less than 15 parts by mass, and
- [0055] the amount CSB of the styrene butadiene rubber, the amount BS of the silica, the groove depth MH (mm) of the groove portion, and the groove depth HB (mm)

from the groove opening of the circumferential narrow groove to the width reference position satisfy a following relational expression.

$$(CSB + BS)/(HB - MH) \geq 5$$

[0056] The tread of the tire wears in use. The tire according to the present disclosure can suppress a decrease in wet performance due to wear while reducing rolling resistance not only at the initial stage of wear but also at the middle stage of wear from exposure of the sipe portion of the main lateral groove to exposure of the width reference position of the enlarged width portion in the circumferential narrow groove. A mechanism exhibiting such an effect is not clarified but is inferred as follows.

[0057] The tread is deformed when the tread surface comes into contact with a road surface. This deformation brings the wall surfaces of the circumferential narrow groove into contact with each other at the body portion main body. The main land portions positioned on both sides of the circumferential narrow groove support each other. This suppresses deformation of the tread. The body portion main body can contribute to reduction in rolling resistance. The tread is increased in apparent stiffness. This may cause a decrease in wet performance. However, the groove portion of the main lateral groove connecting between the circumferential grooves adjacent to each other suppresses the decrease in wet performance. It is inferred that the tire can suppress a decrease in wet performance due to wear while reducing rolling resistance in this manner at the initial stage of wear.

[0058] As the tread gradually wears, the circumferential grooves and the like are decreased in groove capacity. This may cause a decrease in wet performance. However, the enlarged width portion is positioned radially inside the body portion. The sipe portion is positioned radially inside the groove portion. The enlarged width portion larger in groove width than the body portion main body is exposed after the body portion main body disappears. The sipe portion smaller in groove width than the groove portion is exposed after the groove portion disappears. The enlarged width portion and the sipe portion can contribute to suppressing a decrease in wet performance. The groove depth MH of the groove portion is smaller than the groove depth HB from the groove opening of the circumferential narrow groove to the width reference position. This avoids simultaneous exposure of the sipe portion and a portion having a groove width larger than 2.0 times the minimum groove width of the body portion main body. This suppresses uneven wear due to a rapid change in pattern. Each of the main lateral groove and the circumferential narrow groove can stably exhibit its function.

[0059] Wear decreases volume of the tread. The portion having a groove width larger than 2.0 times the minimum groove width of the body portion main body is exposed after the sipe portion is exposed. However, the tread is decreased in deformation allowance and is thus increased in apparent stiffness. The increase in stiffness can contribute to reduction in rolling resistance.

[0060] The increase in stiffness advantageously affects rolling resistance but disadvantageously affects wet performance. However, the rubber composition forming the tread

of the tire contains a styrene butadiene rubber and silica. This increases a glass transition temperature (T_g) of the rubber component as well as improves a road surface following property in a micro-deformation region. The tread can contribute to improvement of wet performance regardless of the stage of wear. In particular, the amount CSB of the styrene butadiene rubber, the amount BS of the silica, the groove depth MH of the groove portion, and the groove depth HB from the groove opening of the circumferential narrow groove to the width reference position are set to satisfy the above relational expression. Accordingly, the styrene butadiene rubber and the silica synergistically suppress a decrease in wet performance also at the middle stage of wear from exposure of the sipe portion of the main lateral groove to exposure of the width reference position of the enlarged width portion in the circumferential narrow groove. The tire can suppress a decrease in wet performance while maintaining low rolling resistance from the start of use until the tire needs to be replaced.

[0061] The present disclosure provides the tire that can suppress a decrease in wet performance due to wear while reducing rolling resistance.

[0062] Preferably, the rubber component further includes a natural rubber and a butadiene rubber, and the amount CSB of the styrene butadiene rubber, an amount CN of the natural rubber, and an amount CB of the butadiene rubber in 100 parts by mass of the rubber component satisfy a following relational expression.

$$CN \geq CSB + CB$$

[0063] When the rubber component further includes the natural rubber (hereinafter, NR) and the butadiene rubber (hereinafter, BR) so as to satisfy the above relational expression, it is inferred that the silica is enhanced in dispersibility in the rubber composition while durability of the tread is maintained. In this case, it is inferred that the tire can suppress a decrease in wet performance due to wear while reducing rolling resistance.

[0064] Preferably, an amount CS of the silica in 100 parts by mass of the filler is not less than 40 parts by mass in 100 parts by mass. Accordingly, the tread can further improve the road surface following property in the micro-deformation region and the tire can improve wet performance regardless of the stage of wear.

[0065] Preferably, the silica includes silica made from a biomass material. This is because such silica can contribute to reduction in environmental load.

[0066] Preferably, the filler includes silica having an average primary particle diameter of not greater than 16 nm. This is because such silica can contribute to improvement of wear resistance and durability.

[0067] Preferably, the filler further includes carbon black, and the carbon black includes recycled carbon black. This is because the recycled carbon black may be able to contribute to reduction of environmental load as well as reduce friction between a surface thereof and a rubber molecular chain to suppress heat generation.

[0068] Preferably, the filler further includes carbon black, and the carbon black includes carbon black having an average primary particle diameter of not greater than 19 nm.

This is because such carbon black can contribute to improvement of wear resistance and durability.

[0069] Preferably, the rubber composition further contains a resin component. This is because the resin component can contribute to improvement of wet performance.

[0070] Preferably, a land ratio defined below is not less than 75%. In this case, the land portions are likely to support each other to effectively increase stiffness of the tread. The tire can be effectively reduced in rolling resistance as well as can be improved in wear resistance.

[0071] Land ratio: a ratio of a total area value of ground-contact surfaces of a plurality of land portions included in a ground-contact surface to an area value of an entirety of the ground-contact surface, the ground-contact surface being obtained by: applying a load, which is 100% of a normal load, to the tire, which is fitted on a normal rim and whose internal pressure is adjusted to a normal internal pressure, with a camber angle as 0 degrees; and bringing the tire into contact with a flat road surface.

[0072] Preferably, each of the main blocks includes a transverse sipe traversing the main block, the transverse sipe includes a sipe body and a tubular portion positioned radially inside the sipe body, and the tubular portion is larger in groove width than the sipe body.

[0073] The sipe body can thus function as an edge component. This maintains excellent wet performance. Furthermore, the tread is deformed and wall surfaces of the sipe body come into tight contact with each other. The wall surfaces thus restrain each other to effectively increase stiffness of the tread. At the initial stage of wear, the sipe body can effectively contribute to maintaining wet performance and reducing rolling resistance. The tubular portion is exposed after the sipe body disappears. The tubular portion thus exposed after the sipe body disappears can contribute to suppressing a decrease in wet performance.

[0074] Preferably, a groove bottom of the groove portion or the width reference position is positioned between a radially outer end and a radially inner end of the tubular portion.

[0075] Accordingly, the tubular portion is exposed after exposure of the groove portion until exposure of the portion having a groove width larger than 2.0 times the minimum groove width of the body portion main body. This period has a large change in pattern, but the tire can maintain excellent wet performance.

[0076] Preferably, the plurality of main land portions includes an inner main land portion positioned between the circumferential narrow grooves adjacent to each other, and the sipe body of the transverse sipe included in the main block of the inner main land portion extends in a zigzag manner in a longitudinal direction and a depth direction.

[0077] Accordingly, when the tread is deformed and the wall surfaces of the sipe body come into tight contact with each other, the wall surfaces restrain each other so as to effectively increase stiffness of the tread. While maintaining wet performance, the tire can be effectively reduced in rolling resistance as well as can be improved in wear resistance.

[0078] Preferably, the circumferential narrow groove includes a first narrow groove close to a first end as one end of the tread surface, a second narrow groove close to a second end as another end of the tread surface, and a connection narrow groove connecting the first narrow groove and the second narrow groove, and the first narrow

groove and the second narrow groove are alternately disposed circumferentially. As described above, when force is applied to deform the tread, the wall surfaces of the circumferential narrow groove come into contact with each other at the body portion. The circumferential narrow groove circumferentially extends while meandering, and the wall surfaces are thus effectively engaged with each other. The main land portions positioned on the both sides of the circumferential narrow groove restrain each other. The tread is increased in apparent stiffness. This effectively suppresses deformation of the tread. The tire can be effectively reduced in rolling resistance as well as can be improved in wear resistance.

[0079] Thus, the heavy duty tire of the present disclosure can suppress a decrease in wet performance due to wear while reducing rolling resistance.

[Rubber Composition]

[0080] The tread is formed from a rubber composition. The tread is a crosslinked product of the rubber composition. The following will describe the rubber composition for the tread. The rubber composition contains a rubber component and a filler.

[Rubber Component]

[0081] The rubber component includes a styrene butadiene rubber (hereinafter referred to as SBR). The rubber component includes an SBR, and may further include a rubber component other than the SBR, or may be composed of only the SBR.

[SBR]

[0082] The SBR is not particularly limited, and examples of the SBR include solution-polymerized SBRs (S-SBRs), emulsion-polymerized SBRs (E-SBRs), and modified SBRs thereof (modified S-SBRs and modified E-SBRs). Examples of modified SBRs include modified SBRs in which the terminals and/or the main chain thereof is modified, and modified SBRs coupled by using tin, a silicon compound, or the like (a condensate, one having a branch structure, etc.). Among them, S-SBRs and modified SBRs are preferable as SBRs included in the rubber component. Furthermore, hydrogenated products of these SBRs (hydrogenated SBRs), etc., can also be used as SBRs in this rubber composition. One of these SBRs may be selected and used alone, or two or more of these SBRs may be selected and used in combination.

[0083] The SBR has excellent viscoelastic properties in a region highly correlated with wet performance (specifically, grip performance on a wet road surface), and has excellent compatibility and reactivity with silica described later. The SBR is considered to be able to contribute to improvement of wet performance and wear resistance.

[0084] From the viewpoint of being able to contribute to improvement of wet performance and wear resistance, the styrene content of the SBR is preferably not less than 5% by mass, more preferably not less than 7% by mass, and further preferably not less than 9% by mass. The styrene content of the SBR is preferably not greater than 24% by mass, more preferably not greater than 18% by mass, and further preferably not greater than 16% by mass. The styrene content of the SBR is calculated by ¹H-NMR measurement.

[0085] The vinyl content of the SBR is not less than 26% by mole. This is because, if the vinyl content is less than 26% by mole, it is difficult to improve wet performance and wear resistance to the degree required for tire performance. The vinyl content is preferably not less than 27% by mole, more preferably not less than 28% by mole, further preferably not less than 29% by mole, and particularly preferably not less than 30% by mole. The vinyl content of the SBR is preferably not greater than 45% by mole, more preferably not greater than 44% by mole, further preferably not greater than 43% by mole, and particularly preferably not greater than 42% by mole. The vinyl content (1,2-bond butadiene unit content) of the SBR is measured by infrared absorption spectrometry.

[0086] From the viewpoint of improving wet performance, the glass transition temperature (T_g) of the SBR is preferably not lower than -80° C., more preferably not lower than -70° C., and further preferably not lower than -65° C. From the viewpoint of reducing rolling resistance, the T_g of the SBR is preferably not higher than -40° C., more preferably not higher than -45° C., further preferably not higher than -50° C., and particularly preferably not higher than -55° C. The T_g of the SBR is obtained by performing differential scanning calorimetry (DSC) in accordance with JIS K7121 for "pure SBR content" obtained by removing elongation oil using acetone in accordance with JIS K6229.

[0087] From the viewpoint of improving wear resistance, the weight-average molecular weight (M_w) of the SBR is preferably not less than 100 thousand, more preferably not less than 150 thousand, and further preferably not less than 190 thousand. From the viewpoint of crosslinking uniformity, etc., the M_w of the SBR is preferably not greater than 2.5 million, more preferably not greater than 2 million, and further preferably not greater than 1 million. The M_w of the SBR can be obtained by conversion, based on a polystyrene standard, of a value measured by gel permeation chromatography (GPC) (e.g., GPC-8000 series manufactured by Tosoh Corporation, detector: differential refractometer, column: TSKGEL SUPERMULTIPORE HZ-M manufactured by Tosoh Corporation).

[0088] As described above, the amount CSB of the SBR in 100 parts by mass of the rubber component is not less than 10 parts by mass. The SBR can effectively contribute to improvement of wear resistance and wet performance. From this viewpoint, the amount CSB is preferably not less than 15 parts by mass, more preferably not less than 17 parts by mass, and further preferably not less than 19 parts by mass. From the viewpoint of maintaining good wear resistance, the amount CSB is preferably not greater than 60 parts by mass, more preferably not greater than 40 parts by mass, and further preferably not greater than 25 parts by mass.

[0089] As described above, the rubber component can include another rubber component other than the SBR. As the other rubber component other than the SBR, a cross-linkable rubber component that is generally used in the tire industry can be used. Examples of such a rubber component include isoprene-based rubber, butadiene rubber (BR), styrene-isoprene-butadiene copolymer rubber (SIBR), styrene-isobutylene-styrene block copolymer (SIBS), chloroprene rubber (CR), acrylonitrile-butadiene rubber (NBR), hydrogenated nitrile rubber (HNBR), butyl rubber (IIR), ethylene-propylene rubber, polynorbornene rubber, silicone rubber, polyethylene chloride rubber, fluororubber (FKM), acrylic rubber (ACM), and hydrazine rubber. One of these other rubber

components may be selected and used alone, or two or more of these other rubber components may be selected and used in combination.

[0090] The rubber component of the rubber composition for the tread preferably includes an isoprene-based rubber and a BR as rubber components other than the SBR.

[Isoprene-Based Rubber]

[0091] Examples of the isoprene-based rubber include natural rubber (NR), polyisoprene rubber (IR), reformed NR, modified NR, and modified IR. As the NR, for example, NRs that are generally used in the tire industry, such as SIR20, RSS #3, and TSR20, can be used. The IR is not particularly limited, and, as the IR, for example, IRs that are generally used in the tire industry, such as IR2200, can be used. Examples of the reformed NR include deproteinized natural rubber (DPNR) and ultra-pure natural rubber (UPNR), examples of the modified NR include epoxidized natural rubber (ENR), hydrogenated natural rubber (HNR), and grafted natural rubber, and examples of the modified IR include epoxidized isoprene rubber, hydrogenated isoprene rubber, and grafted isoprene rubber. These rubbers may be used individually, or two or more of these rubbers may be used in combination. Among them, NR is preferable. The rubber component of the rubber composition for the tread preferably includes an NR and a BR as rubber components other than the SBR.

[0092] In the case where the rubber component includes an NR, from the viewpoint of increasing the strength of the tread and improving wear resistance, the amount CN of the NR in 100 parts by mass of the rubber component is preferably not less than 30 parts by mass, more preferably not less than 45 parts by mass, and further preferably not less than 55 parts by mass. The amount CN is preferably not greater than 80 parts by mass, more preferably not greater than 70 parts by mass, and further preferably not greater than 65 parts by mass.

[Butadiene Rubber]

[0093] The butadiene rubber (BR) is not particularly limited, and, for example, BRs that are generally used in the tire industry, such as a BR having a cis content of less than 50% by mass (low-cis BR), a BR having a cis content of not less than 90% by mass (high-cis BR), a rare-earth element-based butadiene rubber synthesized using a rare-earth element-based catalyst (rare-earth element-based BR), a BR containing syndiotactic polybutadiene crystals (SPB-containing BR), and modified BRs (high-cis modified BR, low-cis modified BR), can be used. These BRs may be used individually, or two or more of these BRs may be used in combination. The cis content of the BR is a value calculated by infrared absorption spectrometry.

[0094] In the case where the rubber component includes a BR, from the viewpoint of improving wear resistance, the amount CB of the BR in 100 parts by mass of the rubber component is preferably not less than 5 parts by mass and more preferably not less than 15 parts by mass. The amount CB of the BR is preferably not greater than 40 parts by mass and more preferably not greater than 25 parts by mass.

[0095] In the case where the rubber component further includes an NR and a BR in addition to the SBR, as described above, the amount CN of the NR is preferably equal to the sum of the amount CSB of the SBR and the

amount CB of the BR or larger than the sum of the amount CSB of the SBR and the amount CB of the BR. This is because the dispersibility of silica in the rubber composition is enhanced while the durability of the tread is maintained. In this case, it is inferred that the tire can suppress a decrease in wet performance due to wear while reducing rolling resistance. From this viewpoint, the amount CN of the NR is more preferably larger than the sum of the amount CSB of the SBR and the amount CB of the BR. In other words, the amount CN of the NR, the amount CSB of the SBR, and the amount CB of the BR more preferably satisfy the following relational expression.

$$CN > CSB + CB$$

[Filler]

[0096] As described above, the rubber composition for the tread contains a filler, and the filler includes silica. In other words, the rubber composition contains silica as a filler.

[0097] The filler more preferably includes carbon black and silica, and may include only carbon black and silica. In other words, the rubber composition more preferably contains carbon black and silica as a filler, and the filler may be composed of only carbon black and silica.

[Silica]

[0098] The silica is not particularly limited, and silicas that are generally used in the tire industry, such as silica prepared by a dry process (anhydrous silica) and silica prepared by a wet process (hydrous silica), can be used. From the viewpoint of environmental load, silica made from a biomass material (e.g., amorphous silica purified from rice husks) may also be used as described above. Among them, hydrous silica prepared by a wet process is preferable for the reason that it has a higher silanol group content. These silicas may be used individually, or two or more of these silicas may be used in combination.

[0099] Silica made from a biomass material can be obtained, for example, by: extracting silicate from rice husk ashes obtained by burning rice husks, with a sodium hydroxide solution; using the silicate to react with sulfuric acid in the same way as conventional wet silica; and then filtering, washing with water, drying, and pulverizing the precipitated silicon dioxide produced.

[0100] It should be noted that when silica crystallizes, the silica is insoluble in water, and silicic acid, which is a component of the silica, cannot be utilized. The crystallization of silica in the rice husk ash can be suppressed by controlling the combustion temperature and the combustion time (see Japanese Laid-Open Patent Publication No. 2009-2594, Akita Prefectural University Web Journal B/2019, vol. 6, p. 216-222, etc.).

[0101] The amorphous silica extracted from rice husks may be ones commercially available from Wilmar International Limited, etc.

[0102] From the viewpoint of improving wear resistance and durability, the average primary particle diameter of the silica is preferably not greater than 22 nm, more preferably not greater than 19 nm, and further preferably not greater than 16 nm. The average primary particle diameter is

preferably not less than 6 nm, more preferably not less than 9 nm, and further preferably not less than 12 nm.

[0103] The average primary particle diameter of the silica can be obtained by observing the silica with a transmission or scanning electron microscope, measuring the outer diameters of 400 or more primary particles of the silica observed in the field of view, and averaging these outer diameters.

[0104] From the viewpoint of improving wear resistance and durability, the nitrogen adsorption specific surface area (N_2SA) of the silica is preferably not less than 100 m²/g, more preferably not less than 110 m²/g, and further preferably not less than 120 m²/g. This nitrogen adsorption specific surface area is preferably not greater than 500 m²/g, more preferably not greater than 350 m²/g, and further preferably not greater than 250 m²/g.

[0105] The nitrogen adsorption specific surface area (N_2SA) of the silica is measured by the BET method according to ASTM D3037-93.

[0106] The amount BS of the silica per 100 parts by mass of the rubber component is not less than 15 parts by mass. The silica can effectively reinforce the tread. Since the stiffness of the tread is increased, wear resistance and durability are improved. From this viewpoint, the amount BS of the silica is preferably not less than 17 parts by mass, more preferably not less than 19 parts by mass, and further preferably not less than 20 parts by mass. From the viewpoint of being able to obtain flexibility to alleviate stress, the amount BS of the silica is preferably not greater than 70 parts by mass, more preferably not greater than 50 parts by mass, and further preferably not greater than 35 parts by mass.

[Carbon Black]

[0107] The carbon black is not particularly limited, and, for example, carbon blacks that can be generally used in the tire industry, such as GPF, FEF, HAF, ISAF, and SAF, can be used. In addition, from the viewpoint of reducing environmental load and from the viewpoint of being able to reduce friction between the carbon black surface and a rubber molecular chain to suppress heat generation, recycled carbon black (rCB) obtained from the pyrolysis of used tires can also be used for the tire. These carbon blacks may be used individually, or two or more of these carbon blacks may be used in combination.

[0108] In the present disclosure, to distinguish from recycled carbon black (rCB), the above-described carbon blacks that can be generally used in the tire industry, such as GPF, FEF, HAF, ISAF, and SAF, are also referred to as standard carbon black (sCB).

[0109] Recycled carbon black can be obtained from the pyrolysis process of used pneumatic tires, as described above. For example, European Patent Application Publication No. 3427975 refers to "Rubber Chemistry and Technology", Vol. 85, No. 3, pages 408-449 (2012), especially pages 438, 440, and 442, and states that recycled carbon black can be obtained by pyrolysis of organic materials at 550 to 800° C. with exclusion of oxygen, or by vacuum pyrolysis at relatively low temperatures ([0027]). Carbon blacks obtained from such pyrolysis processes usually lack functional groups on the surfaces thereof, as mentioned in of Japanese Patent No. 6856781 (A Comparison of Surface Morphology And Chemistry of Pyrolytic Carbon Blacks with Commercial Carbon Blacks, Powder Technology 160 (2005) 190-193).

[0110] The recycled carbon black may lack functional groups on the surface thereof or may be treated so as to include functional groups on the surface thereof. The treatment to be performed so as to include functional groups on the surface of the recycled carbon black can be carried out by ordinary methods. For example, in European Patent Application Publication No. 3173251, carbon black obtained from a pyrolysis process is treated with potassium permanganate under acidic conditions to obtain carbon black containing hydroxyl and/or carboxyl groups on the surface thereof. Also, in Japanese Patent No. 6856781, carbon black obtained from a pyrolysis process is treated with an amino acid compound containing at least one thiol or disulfide group to obtain carbon black whose surface has been activated. The recycled carbon black according to the present embodiment also includes carbon black that has been treated so as to include functional groups on the surface thereof.

[0111] As the recycled carbon black, recycled carbon blacks commercially available from Strebl Green Carbon Pte Ltd, LDCarbon, etc., can be used.

[0112] From the viewpoint of improving wear resistance and durability, the average primary particle diameter of the carbon black is preferably not greater than 25 nm, more preferably not greater than 22 nm, and further preferably not greater than 19 nm. The average primary particle diameter is preferably not less than 6 nm, more preferably not less than 9 nm, and further preferably not less than 12 nm.

[0113] The average primary particle diameter of the carbon black can be obtained by observing the carbon black with a transmission or scanning electron microscope, measuring the outer diameters of 400 or more primary particles of the carbon black observed in the field of view, and averaging these outer diameters.

[0114] From the viewpoint of improving wear resistance and durability, the nitrogen adsorption specific surface area (N_2SA) of the carbon black is preferably not less than 10 m²/g, more preferably not less than 20 m²/g, and further preferably not less than 30 m²/g. This nitrogen adsorption specific surface area (N_2SA) is preferably not greater than 250 m²/g, more preferably not greater than 200 m²/g, and further preferably not greater than 150 m²/g. The nitrogen adsorption specific surface area (N_2SA) of the carbon black is measured according to JIS K6217-2: 2017.

[0115] In the case where the rubber composition contains carbon black, from the viewpoint of exhibiting reinforcing action and the viewpoint of preventing deterioration due to UV light, an amount BC of the carbon black per 100 parts by mass of the rubber component is preferably not less than 5 parts by mass, more preferably not less than 15 parts by mass, and further preferably not less than 25 parts by mass. From the viewpoint that the tread can obtain flexibility to alleviate stress, the amount BC is preferably not greater than 70 parts by mass, more preferably not greater than 60 parts by mass, and further preferably not greater than 50 parts by mass.

[0116] The amount of the recycled carbon black in 100 parts by mass of the carbon black is not particularly limited, and can be, for example, greater than 1 part by mass, greater than 5 parts by mass, greater than 10 parts by mass, greater than 20 parts by mass, greater than 25 parts by mass, or greater than 30 parts by mass. From the viewpoint of exhibiting the reinforcing action of the carbon black, the amount of the recycled carbon black is preferably less than

95 parts by mass, more preferably less than 90 parts by mass, and further preferably less than 85 parts by mass.

[Other Fillers]

[0117] As fillers other than the silica and the carbon black, fillers that are generally used in the tire industry, such as aluminum hydroxide, calcium carbonate, alumina, clay, and talc, can be blended.

[0118] From the viewpoint that the tread can further improve a road surface following property in a micro-deformation region and the tire can improve wet performance regardless of the stage of wear, the amount CS of the silica in 100 parts by mass of the filler is preferably not less than 20 parts by mass, more preferably not less than 30 parts by mass, and further preferably not less than 40 parts by mass. The amount CS is preferably not greater than 95 parts by mass, more preferably not greater than 80 parts by mass, and further preferably not greater than 65 parts by mass.

[0119] From the viewpoint of improving wear resistance and durability, the total amount of the fillers per 100 parts by mass of the rubber component is preferably not less than 45 parts by mass, more preferably not less than 50 parts by mass, and further preferably not less than 55 parts by mass. From the viewpoint that the tread can obtain flexibility to alleviate stress, the total amount of the fillers is preferably not greater than 80 parts by mass, more preferably not greater than 70 parts by mass, and further preferably not greater than 65 parts by mass.

[Silane Coupling Agent]

[0120] As described above, the rubber composition contains silica as a filler. The silica is preferably used in combination with a silane coupling agent. The silane coupling agent is not particularly limited, and any silane coupling agent that is conventionally used in combination with silica in the tire industry can be used. Examples of the silane coupling agent include: mercapto-based silane coupling agents such as 3-mercaptopropyltrimethoxysilane and NXT-Z100, NXT-Z45, and NXT manufactured by Momentive Performance Materials, Inc.; sulfide-based silane coupling agents such as bis(3-triethoxysilylpropyl)disulfide and bis(3-triethoxysilylpropyl)tetrasulfide; thioester-based coupling agents such as 3-octanoylthio-1-propyltriethoxysilane, 3-hexanoylthio-1-propyltriethoxysilane, and 3-octanoylthio-1-propyltrimethoxysilane; vinyl-based silane coupling agents such as vinyltriethoxysilane and vinyltrimethoxysilane; amino-based silane coupling agents such as 3-amino-propyltriethoxysilane, 3-aminopropyltrimethoxysilane, and 3-(2-aminoethyl)aminopropyltriethoxysilane; glycidoxy-based silane coupling agents such as γ -glycidoxypropyltriethoxysilane and γ -glycidoxypropyltrimethoxysilane; nitro-based silane coupling agents such as 3-nitropropyltrimethoxysilane and 3-nitropropyltriethoxysilane; and chloro-based silane coupling agents such as 3-chloropropyltrimethoxysilane and 3-chloropropyltriethoxysilane. Among them, sulfide-based silane coupling agents and/or mercapto-based silane coupling agents are preferable, and sulfide-based silane coupling agents are more preferable. One of these silane coupling agents may be used alone, or two or more of these silane coupling agents may be used in combination.

[0121] From the viewpoint of enhancing the dispersibility of the silica, the amount of the silane coupling agent per 100

parts by mass of the rubber component is preferably not less than 0.5 parts by mass, more preferably not less than 1.0 part by mass, further preferably not less than 2.0 parts by mass, and particularly preferably not less than 4.0 parts by mass. From the viewpoint of suppressing a decrease in wear resistance, the amount of the silane coupling agent is preferably not greater than 20 parts by mass, more preferably not greater than 15 parts by mass, and further preferably not greater than 10 parts by mass.

[0122] From the viewpoint of enhancing the dispersibility of the silica, the amount of the silane coupling agent per 100 parts by mass of the silica is preferably not less than 1 part by mass, more preferably not less than 3 parts by mass, further preferably not less than 5 parts by mass, and particularly preferably not less than 8 parts by mass. From the viewpoint of reduction of cost and improvement of processability, the amount of the silane coupling agent is preferably not greater than 20 parts by mass, more preferably not greater than 18 parts by mass, and further preferably not greater than 16 parts by mass.

[Other Ingredients]

[0123] In addition to the above components, the rubber composition according to the present embodiment can contain ingredients that are conventionally and generally used in the tire industry, such as a softener, wax, stearic acid, zinc oxide, an antioxidant, a vulcanizing agent, and a vulcanization accelerator, as appropriate.

[0124] Examples of the softener include a resin component, an oil, and a liquid rubber.

[0125] The resin component that can be used in the present embodiment is not particularly limited, resins that are commonly used in the tire industry can be used, and examples of such resins include adhesive resins such as C9-based resins, C5-based resins, C5C9-based resins, dicyclopentadiene-based resins, aromatic vinyl-based resins, coumarone-based resins, indene-based resins, terpene-based resins, rosin-based resins, and phenol-based resins. One of these resin components may be used alone, or two or more of these resin components may be used in combination.

[0126] C9-based resins refer to resins obtained by polymerizing C9 fractions, and may be resins obtained by polymerizing C9 fractions alone, or may be copolymers obtained by copolymerizing C9 fractions and other components. For example, a resin obtained by copolymerizing dicyclopentadiene (DCPD) and a C9 fraction is referred to as DCPD/C9 resin. These resins may also be hydrogenated or modified. Examples of C9 fractions include petroleum fractions having 8 to 10 carbon atoms such as vinyltoluene, alkylstyrene, coumarone, indene, methylindene, and dicyclopentadiene. One of these C9-based resins may be used alone, or two or more of these C9-based resins may be used in combination.

[0127] C5-based resins refer to resins obtained by polymerizing C5 fractions, and these resins may be hydrogenated or modified. Examples of C5 fractions other than dicyclopentadiene include petroleum fractions having 4 to 5 carbon atoms such as cyclopentadiene, isoprene, pentane, isopentane, neopentane, pentene, and pentadiene. One of these C5-based resins may be used alone, or two or more of these C5-based resins may be used in combination.

[0128] C5C9-based resins refer to resins obtained by copolymerizing the C5 fractions and the C9 fractions, and these resins may be hydrogenated or modified. As C5C9-based petroleum resins, for example, products commercially

available from Tosoh Corporation, Zibo Luhua Hongjin New Material Group Co., Ltd., etc., can be used. One of these C5C9-based resins may be used alone, or two or more of these C5C9-based resins may be used in combination.

[0129] Dicyclopentadiene-based resins refer to resins containing cyclopentadiene (CPD) or dicyclopentadiene (DCPD) as a monomer component, and these resins may be hydrogenated or modified. Examples of dicyclopentadiene-based resins include DCPD/C9 resins containing dicyclopentadiene and the C9 fractions as monomer components (the DCPD/C9 resins may be hydrogenated or modified). DCPD/C9 resins containing dicyclopentadiene and styrene as monomer components are preferable, and DCPD/C9 resins containing dicyclopentadiene, styrene, and indene as monomer components are particularly preferable. As dicyclopentadiene-based resins, for example, products commercially available from Exxon Mobil Corporation, ENEOS Corporation, Zeon Corporation, Maruzen Petrochemical Co., Ltd., etc., can be used. One of these dicyclopentadiene-based resins may be used alone, or two or more of these dicyclopentadiene-based resins may be used in combination.

[0130] Aromatic vinyl-based resins refer to resins each containing an aromatic vinyl compound such as styrene, α -methylstyrene, vinyltoluene, and p-chlorostyrene as a monomer component whose amount is the largest, and these resins may be hydrogenated or modified. As an aromatic vinyl-based resin, a homopolymer of α -methylstyrene or styrene or a copolymer of α -methylstyrene and styrene is preferable, and a copolymer of α -methylstyrene and styrene is more preferable, for the reasons that the polymer is economic, is easily processed, and has excellent heat generation properties. As aromatic vinyl-based resins, for example, products commercially available from Kraton Corporation, Eastman Chemical Company, Mitsui Chemicals, Inc., etc., can be used. One of these aromatic vinyl-based resins may be used alone, or two or more of these aromatic vinyl-based resins may be used in combination.

[0131] Coumarone-based resins refer to resins containing coumarone as a monomer component, and these resins may be hydrogenated or modified. Examples of coumarone-based resins include coumarone-indene resins containing coumarone and indene as monomer components, and coumarone-indene-styrene resins containing coumarone, indene, and styrene as monomer components. One of these coumarone-based resins may be used alone, or two or more of these coumarone-based resins may be used in combination.

[0132] Indene-based resins refer to resins containing indene as a monomer component, and these resins may be hydrogenated or modified. Examples of indene-based resins include coumarone-indene resins containing coumarone and indene as monomer components, and coumarone-indene-styrene resins containing coumarone, indene, and styrene as monomer components. One of these indene-based resins may be used alone, or two or more of these indene-based resins may be used in combination.

[0133] Terpene-based resins refer to resins each containing a terpene compound such as α -pinene, β -pinene, limonene, and dipentene as a monomer component whose amount is the largest, and these resins may be hydrogenated or modified. Specific examples of terpene-based resins include: polyterpene resins each containing one or more of the terpene compounds alone as a monomer component; aromatic modified terpene resins each containing the terpene

compound and an aromatic compound as monomer components; and terpene-phenol resins each containing the terpene compound and a phenol-based compound as monomer components. Examples of aromatic compounds as monomer components of aromatic modified terpene resins include styrene, α -methylstyrene, vinyltoluene, and divinyltoluene. Examples of phenol-based compounds as monomer components of terpene-phenol resins include phenol, bisphenol A, cresol, and xylene. One of these terpene-based resins may be used alone, or two or more of these terpene-based resins may be used in combination.

[0134] Rosin-based resins refer to resins containing rosin acid compounds such as abietic acid, neoabietic acid, palustric acid, and isopimaric acid, and these resins may be hydrogenated or modified. The rosin-based resins are not particularly limited, and examples of the rosin-based resins include natural rosin resins, and rosin-modified resin modified by hydrogenation, disproportionation, dimerization, esterification, etc. One of these rosin-based resins may be used alone, or two or more of these rosin-based resins may be used in combination.

[0135] Phenol-based resins refer to resins each containing a phenol compound such as phenol and cresol as a monomer component whose amount is the largest. The phenol-based resins are not particularly limited, and examples of the phenol-based resins include phenol formaldehyde resins, alkylphenol formaldehyde resins, alkylphenol acetylene resins, and oil-modified phenol formaldehyde resins. One of these phenol-based resins may be used alone, or two or more of these phenol-based resins may be used in combination.

[0136] From the viewpoint of wet performance, the softening point of the resin component is preferably not lower than 80° C., more preferably not lower than 90° C., and further preferably not lower than 100° C. From the viewpoint of processability and improvement of the dispersibility of the rubber component and the fillers, the softening point of the resin component is preferably not higher than 150° C., more preferably not higher than 140° C., and further preferably not higher than 130° C. The softening point of the resin is a temperature that is measured with a ring and ball softening point measuring device according to 7.7 in JIS K 6220-1: 2015 and at which a ball has descended.

[0137] In the case where the rubber composition contains a resin component, from the viewpoint of wet performance, the amount of the resin component per 100 parts by mass of the rubber component is preferably not less than 1 part by mass, more preferably not less than 3 parts by mass, and further preferably not less than 5 parts by mass. From the viewpoint of suppression of heat generation, the amount of the resin component is preferably not greater than 60 parts by mass, more preferably not greater than 50 parts by mass, further preferably not greater than 40 parts by mass, and particularly preferably not greater than 30 parts by mass.

[0138] Examples of the oil include process oils, vegetable fats and oils, and animal fats and oils. Examples of the process oils include paraffin-based process oils, naphthene-based process oils, and aroma-based process oils. In addition, a process oil that has a low content of a polycyclic aromatic (PCA) compound and for which environmental impact is taken into consideration can also be used. Examples of the low PCA content process oil include a mild extraction solvate (MES), a treated distillate aromatic extract (TDAE), and a heavy naphthenic oil.

[0139] In the case where the rubber composition contains an oil, from the viewpoint of improving processability, the amount of the oil per 100 parts by mass of the rubber component is preferably not less than 1 part by mass, more preferably not less than 3 parts by mass, and further preferably not less than 5 parts by mass. From the viewpoint of improving wear resistance, the amount of the oil is preferably not greater than 90 parts by mass, more preferably not greater than 70 parts by mass, further preferably not greater than 50 parts by mass, and particularly preferably not greater than 30 parts by mass.

[0140] The liquid rubber is not particularly limited as long as it is a polymer in a liquid state at room temperature (25° C.), and examples of the liquid rubber include liquid butadiene rubber (liquid BR), liquid styrene-butadiene rubber (liquid SBR), liquid isoprene rubber (liquid IR), liquid styrene-isoprene rubber (liquid SIR), and liquid farnesene rubber. These liquid rubbers may be used individually, or two or more of these liquid rubbers may be used in combination.

[0141] In the case where the rubber composition contains a liquid rubber, the amount of the liquid rubber per 100 parts by mass of the rubber component is preferably not less than 1 part by mass, more preferably not less than 3 parts by mass, and further preferably not less than 5 parts by mass. The amount of the liquid rubber is preferably not greater than 50 parts by mass, more preferably not greater than 40 parts by mass, and further preferably not greater than 20 parts by mass.

[0142] The wax is not particularly limited, and examples of the wax include: petroleum waxes such as paraffin wax and microcrystalline wax; and synthesized waxes such as polymers of ethylene, propylene, and the like. As commercially available products, products of OUCHI SHINKO CHEMICAL INDUSTRIAL CO., LTD., NIPPON SEIRO CO., LTD., Seiko Chemical Co., Ltd., etc., can be used. These waxes may be used individually, or two or more of these waxes may be used in combination.

[0143] In the case where the rubber composition contains a wax, from the viewpoint of the weather resistance of the rubber, the amount of the wax per 100 parts by mass of the rubber component is preferably not less than 0.5 parts by mass, more preferably not less than 1.0 part by mass, and further preferably not less than 1.5 parts by mass. From viewpoint of preventing whitening of the tire due to blooming, the amount of the wax is preferably not greater than 10 parts by mass and more preferably not greater than 5.0 parts by mass.

[0144] The antioxidant is not particularly limited, and examples of the antioxidant include antioxidants such as amine-based compounds, quinoline-based compounds, quinone-based compounds, phenol-based compounds, imidazole-based compounds, and carbamic acid metal salts. Phenylenediamine-based antioxidants such as N-(1,3-dimethylbutyl)-N'-phenyl-p-phenylenediamine, N-isopropyl-N'-phenyl-p-phenylenediamine, N,N'-diphenyl-p-phenylenediamine, N,N'-di-2-naphthyl-p-phenylenediamine, and N-cyclohexyl-N'-phenyl-p-phenylenediamine, and quinoline-based antioxidants such as a 2,2,4-trimethyl-1,2-dihydroquinoline polymer and 6-ethoxy-2,2,4-trimethyl-1,2-dihydroquinoline are preferable. These antioxidants may be used individually, or two or more of these antioxidants may be used in combination.

[0145] In the case where the rubber composition contains an antioxidant, from the viewpoint of the ozone crack resistance of the rubber, the amount of the antioxidant per 100 parts by mass of the rubber component is preferably not less than 0.5 parts by mass, more preferably not less than 1.0 part by mass, and further preferably not less than 1.5 parts by mass. From the viewpoint of wear resistance and wet grip performance, the amount of the antioxidant is preferably not greater than 10 parts by mass and more preferably not greater than 5.0 parts by mass.

[0146] As the stearic acid, a conventionally known one can be used, and, for example, products of NOF Corporation, Kao Corporation, FUJIFILM Wako Pure Chemical Corporation, Chiba Fatty Acid Co., Ltd., etc., can be used. These stearic acids may be used individually, or two or more of these stearic acids may be used in combination.

[0147] In the case where the rubber composition contains stearic acid, from the viewpoint of processability, the amount of the stearic acid per 100 parts by mass of the rubber component is preferably not less than 0.5 parts by mass, more preferably not less than 1.0 part by mass, and further preferably not less than 1.5 parts by mass. From the viewpoint of a vulcanization rate, the amount of the stearic acid is preferably not greater than 10 parts by mass and more preferably not greater than 5.0 parts by mass.

[0148] As the zinc oxide, a conventionally known one can be used, and, for example, products of Mitsui Mining & Smelting Co., Ltd., Toho Zinc Co., Ltd., HakusuiTech Co., Ltd., SEIDO CHEMICAL INDUSTRY CO., LTD., Sakai Chemical Industry Co., Ltd., etc., can be used. These zinc oxides may be used individually, or two or more of these zinc oxides may be used in combination.

[0149] In the case where the rubber composition contains zinc oxide, from the viewpoint of processability, the amount of the zinc oxide per 100 parts by mass of the rubber component is preferably not less than 0.5 parts by mass, more preferably not less than 1.0 part by mass, and further preferably not less than 1.5 parts by mass. From the viewpoint of wear resistance, the amount of the zinc oxide is preferably not greater than 10 parts by mass and more preferably not greater than 5.0 parts by mass.

[0150] As the vulcanizing agent, sulfur is suitably used. As the sulfur, powdery sulfur, oil-treated sulfur, precipitated sulfur, colloidal sulfur, insoluble sulfur, highly dispersible sulfur, etc., can be used.

[0151] In the case where the rubber composition contains sulfur as a vulcanizing agent, from the viewpoint of ensuring a sufficient vulcanization reaction, the amount of the sulfur per 100 parts by mass of the rubber component is preferably not less than 0.1 parts by mass, more preferably not less than 0.5 parts by mass, and further preferably not less than 1.0 part by mass. From the viewpoint of prevention of deterioration, the amount of the sulfur is preferably not greater than 5.0 parts by mass, more preferably not greater than 4.0 parts by mass, and further preferably not greater than 3.5 parts by mass. When oil-containing sulfur is used as a vulcanizing agent, the amount of the vulcanizing agent is represented as the amount of pure sulfur contained in the oil-containing sulfur.

[0152] Examples of vulcanizing agents other than sulfur include alkylphenol-sulfur chloride condensates, sodium 1,6-hexamethylene dithiosulfate dihydrate, and 1,6-bis(N,N'-dibenzylthiocarbamoyldithio)hexane. As these vulcaniz-

ing agents other than sulfur, products commercially available from Taoka Chemical Co., Ltd., LANXESS, Flexsys, etc., can be used.

[0153] Examples of the vulcanization accelerator include sulfenamide-based vulcanization accelerators, thiazole-based vulcanization accelerators, thiuram-based vulcanization accelerators, thiourea-based vulcanization accelerators, guanidine-based vulcanization accelerators, dithiocarbamic acid-based vulcanization accelerators, aldehyde-amine-based vulcanization accelerators, aldehyde-ammonia-based vulcanization accelerators, imidazoline-based vulcanization accelerators, and xanthate-based vulcanization accelerators. These vulcanization accelerators may be used individually, or two or more of these vulcanization accelerators may be used in combination. Among them, from the viewpoint of more suitably obtaining the desired effect, one or more vulcanization accelerators selected from the group consisting of sulfenamide-based vulcanization accelerators, guanidine-based vulcanization accelerators, and thiazole-based vulcanization accelerators are preferable, and sulfenamide-based vulcanization accelerators are more preferable.

[0154] Examples of the sulfenamide-based vulcanization accelerators include N-tert-butyl-2-benzothiazolyl sulfenamide (TBBS), N-cyclohexyl-2-benzothiazolyl sulfenamide (CBS), and N,N-dicyclohexyl-2-benzothiazolyl sulfenamide (DCBS). Among them, N-tert-butyl-2-benzothiazolyl sulfenamide (TBBS) and N-cyclohexyl-2-benzothiazolyl sulfenamide (CBS) are preferable.

[0155] Examples of the guanidine-based vulcanization accelerators include 1,3-diphenylguanidine (DPG), 1,3-di-o-tolylguanidine, 1-o-tolylbiguanide, a di-o-tolylguanidine salt of dicatchol borate, 1,3-di-o-cumenylguanidine, 1,3-di-o-biphenylguanidine, and 1,3-di-o-cumenyl-2-propionylguanidine. Among them, 1,3-diphenylguanidine (DPG) is preferable.

[0156] Examples of the thiazole-based vulcanization accelerators include 2-mercaptobenzothiazole, a cyclohexylamine salt of 2-mercaptobenzothiazole, and di-2-benzothiazolyl disulfide. Among them, 2-mercaptobenzothiazole is preferable.

[0157] In the case where the rubber composition contains a vulcanization accelerator, the amount of the vulcanization accelerator per 100 parts by mass of the rubber component is preferably not less than 1.0 part by mass, more preferably not less than 1.5 parts by mass, and further preferably not less than 2.0 parts by mass. The amount of the vulcanization accelerator is preferably not greater than 8.0 parts by mass, more preferably not greater than 7.0 parts by mass, further preferably not greater than 6.0 parts by mass, and particularly preferably not greater than 5.0 parts by mass. When the amount of the vulcanization accelerator is set to be within such a range, it tends to be possible to ensure fracture strength and elongation.

[0158] The rubber composition is produced, for example, by kneading the respective components described above, using a rubber kneading device such as an open roll and a Banbury mixer.

[0159] As for the kneading conditions, in a base kneading step of kneading the additives other than the vulcanizing agent and the vulcanization accelerator, the kneading temperature is normally 100 to 180° C. and preferably 120 to 170° C. In a finish kneading step of kneading the vulcanizing

agent and the vulcanization accelerator, the kneading temperature is normally 120° C. or lower and preferably 85 to 110° C.

[0160] The produced rubber composition is processed into a predetermined shape using an extruder or the like. In a forming machine, the processed rubber composition is combined with sidewalls, etc., to prepare a green tire (unvulcanized tire). The green tire is vulcanized in a mold incorporated in a vulcanizing machine, thereby obtaining a tire. The tire is a crosslinked product of the green tire. The vulcanization temperature is normally 140 to 190° C. and preferably 150 to 185° C. The vulcanization time is normally 5 to 15 minutes.

[0161] The rubber composition described above is used for the tread of a tire (specifically, a cap portion which comes into contact with a road surface during running).

[0162] Next, a tire having a tread formed using this rubber composition will be described.

[Tire]

[0163] FIG. 1 is a developed plan view showing a part of a tread 4 of a tire 2 according to an embodiment of the present invention. The tire 2 is mounted to a vehicle such as a truck or a bus. The tire 2 is a heavy duty tire.

[0164] FIG. 1 includes a double-pointed arrow AD indicating an axial direction of the tire 2. The axial direction of the tire 2 means a direction parallel to a rotation axis of the tire 2. FIG. 1 also includes a double-pointed arrow CD indicating a circumferential direction of the tire 2. A direction perpendicular to a sheet of FIG. 1 is a radial direction of the tire 2.

[0165] FIG. 1 further includes a dashed line CL extending circumferentially and indicating an equator plane of the tire 2.

[0166] The tire 2 travelling on a road surface comes into contact with the road surface from a side indicated by an arrow CD1 toward a side indicated by an arrow CD2. The tire 2 includes a former contact portion indicated by the arrow CD1 and a latter contact portion indicated by the arrow CD2.

[0167] FIG. 1 shows an exemplary tread pattern formed on the tread 4. A tread pattern according to the present disclosure will be described hereinafter with reference to the exemplary tread pattern shown in FIG. 1. The present disclosure does not particularly limit an internal structure of the tire 2. Though not detailed, the tire 2 has a typical internal structure of a heavy duty tire.

[0168] FIG. 2 shows a part of the tread pattern in FIG. 1.

[0169] The tread 4 is positioned radially outside the tire 2 and extends circumferentially. The tread 4 has an outer circumferential surface serving as a tread surface 6. The tread surface 6 of the tire 2 comes into contact with a road surface. The tread 4 has the tread surface 6 to come into contact with a road surface.

[0170] The tread 4 is formed from a crosslinked rubber. The tread 4 is a crosslinked product of the above-described rubber composition.

[0171] The tread 4 includes a groove 8 carved therein. The groove 8 thus provided forms a tread pattern.

[0172] The tread surface 6 and the equator plane intersect each other at an equator. Though not shown, in a case where the groove 8 is positioned on the equator plane, the equator is specified based on a virtual outer surface obtained assuming that the groove 8 is not positioned on the equator plane.

[0173] The tread surface 6 has ends indicated as positions TE.

[0174] In a case where a tread surface of a tire has an apparently unidentifiable end, assumed as the end of the tread surface is a position on an outer surface of the tire corresponding to an axially outer end of a ground-contact surface obtained by applying a normal load to the tire in a normal state with a camber angle set to 0 degrees and bringing the tire into contact with a plane.

[0175] The tread surface 6 shown in FIG. 1 has one of the ends TE positioned on a left side of the equator plane, and the end TE is referred to as a first end TE1. The other end TE positioned on a right side of the equator plane is referred to as a second end TE2.

[0176] FIG. 1 indicates a length TW as a width of the tread surface 6. The width TW of the tread surface 6 is an axial distance from the first end TE1 to the second end TE2 of the tread surface 6. The width TW of the tread surface 6 is represented as a length measured along the tread surface 6.

[0177] FIG. 3 is a sectional view taken along a line III-III in FIG. 1. FIG. 3 shows a section of the groove 8, specifically, a shoulder circumferential groove to be described later. The groove 8 will be described in terms of its principal configuration with reference to FIG. 3.

[0178] The groove 8 has a pair of wall surfaces 8W including a groove opening 8M, and a bottom surface 8B including a groove bottom 8T. The groove 8 has a groove width represented as a distance between a first wall surface 8W and a second wall surface 8W as the pair of wall surfaces 8W, that is, a distance between wall surfaces.

[0179] FIG. 3 includes a double-pointed arrow WG indicating a length as the groove width at the groove opening 8M of the groove 8. The groove width WG is represented as the minimum distance between a pair of edges 8E forming the groove opening 8M. In a case where a portion at the groove opening 8M of the groove 8 is processed to be tapered, the groove width at the groove opening 8M of the groove 8 is represented based on a virtual edge obtained assuming that the groove opening is not processed to be tapered.

[0180] FIG. 3 also includes a double-pointed arrow DG indicating a length as a groove depth of the groove 8. The groove depth DG of the groove 8 is represented as the minimum distance from a line segment connecting the left and right edges 8E to the groove bottom 8T of the groove 8.

[0181] The position of the groove 8, the groove width WG, and the groove depth DG are determined as appropriate in accordance with specifications of the tire 2.

[0182] The groove bottom 8T is located at a deepest position in the section of the groove 8. A distance from the line segment connecting the left and right edges 8E forming the groove opening 8M to the bottom surface 8B is measured along a normal line of the line segment. The groove bottom 8T is located at a position with the maximum distance from the line segment to the bottom surface 8B.

[0183] The bottom surface 8B shown in FIG. 3 is curved. The bottom surface 8B may include a plane that may include the groove bottom 8T. In this case, the groove bottom 8T is set as a width center of the plane.

[0184] The groove 8 having the groove width WG less than 1.0 mm at the groove opening 8M is also referred to as sipe. The groove 8 other than the sipe is also referred to as ordinary groove and has the groove width WG not less than 1.0 mm at the groove opening 8M.

[0185] The sipe may include a portion (hereinafter, ordinary groove corresponding portion) having a groove width not less than 1.0 mm between the groove opening 8M and the groove bottom 8T. In this case, the sipe is transformed into an ordinary groove when the tread 4 wears and the ordinary groove corresponding portion is exposed.

[0186] The ordinary groove may include a portion (a sipe corresponding portion) having a groove width less than 1.0 mm between the groove opening 8M and the groove bottom 8T. In this case, the ordinary groove is transformed into a sipe when the tread 4 wears and the sipe corresponding portion is exposed.

[0187] If an ordinary groove has a small groove width and has facing wall surfaces that can come into contact with each other when the tire comes into contact with a road surface, such an ordinary groove is also referred to as a narrow groove. If an ordinary groove has a large groove width and has facing wall surfaces that do not come into contact with each other even when the tire comes into contact with a road surface, such an ordinary groove is also referred to as a wide groove.

[0188] FIG. 3 includes a double-pointed arrow DGC indicating a length as a groove depth of a circumferential groove 10 to be described later. The groove depth DGC of the circumferential groove 10 is exemplarily not less than 10 mm and not greater than 21 mm. From the viewpoint that the tire 2 can exhibit excellent wet performance, the groove depth DGC is preferably not less than 13 mm and not greater than 18 mm.

[0189] The circumferential groove 10 continuously extending in a circumferential direction is carved in the tread 4 of the tire 2. A plurality of circumferential grooves 10 is carved in the tread 4 so as to form a plurality of land portions 12 aligned axially. In other words, the tread 4 includes the plurality of circumferential grooves 10. The plurality of circumferential grooves 10 provides the tread 4 with the plurality of land portions 12.

[0190] In the present disclosure, the plurality of circumferential grooves carved in the tread includes a circumferential groove that is positioned axially outermost and is also referred to as shoulder circumferential groove. The circumferential groove positioned on the equator plane is also referred to as center circumferential groove. In a case where no circumferential groove is provided on the equator plane, the circumferential groove closest to the equator plane is also referred to as center circumferential groove. In a case where the center circumferential groove and the shoulder circumferential groove interpose any circumferential groove, the circumferential groove is also referred to as middle circumferential groove.

[0191] The tread 4 shown in FIG. 1 includes four circumferential grooves 10 aligned axially. The four circumferential grooves 10 include the circumferential groove 10 that is positioned axially outermost and is a shoulder circumferential groove 16. The circumferential groove 10 close to the equator plane is a center circumferential groove 14.

[0192] FIG. 1 includes a double-pointed arrow WGCc indicating a length as a groove width at a groove opening of the center circumferential groove 14. FIG. 1 includes a double-pointed arrow WGCs indicating a length as a groove width at a groove opening of the shoulder circumferential groove 16.

[0193] A ratio (WGCc/TW) of the groove width WGCc of the center circumferential groove 14 to the width TW of the tread surface 6 is not greater than 2.0%.

[0194] As shown in FIG. 1, the groove width WGCs of the shoulder circumferential groove 16 is larger than the groove width WGCc of the center circumferential groove 14. A ratio (WGCs/TW) of the groove width WGCs of the shoulder circumferential groove 16 to the width TW of the tread surface 6 exceeds 2.0%. Specifically, the ratio (WGCs/TW) is preferably not less than 4.0% and not greater than 10%.

[0195] The shoulder circumferential groove 16 of the tire 2 includes outer peaks 16s close to the end TE of the tread surface 6 and inner peaks 16u close to the equator plane. The outer peaks 16s and the inner peaks 16u are alternately aligned circumferentially. The shoulder circumferential groove 16 extends circumferentially while alternately passing through the outer peaks 16s and the inner peaks 16u. The shoulder circumferential groove 16 extends zigzag in the circumferential direction. The shoulder circumferential groove 16 may alternatively extend straight in the circumferential direction.

[0196] As to be described later, the center circumferential groove 14 is a narrow groove having facing wall surfaces that can come into contact with each other when the tire 2 comes into contact with a road surface. The shoulder circumferential groove 16 is a wide groove having facing wall surfaces that do not come into contact with each other even when the tire 2 comes into contact with a road surface.

[0197] The tire 2 includes the center circumferential groove 14 as a circumferential narrow groove 18 and the shoulder circumferential groove 16 as a circumferential wide groove 20.

[0198] The four circumferential grooves 10 carved in the tread 4 of the tire 2 include a pair of circumferential narrow grooves 18 and a pair of circumferential wide grooves 20. The circumferential wide grooves 20 have the groove width WGCs larger than the groove width WGCc of the circumferential narrow grooves 18.

[0199] In the present disclosure, the plurality of land portions formed on the tread includes a land portion that is positioned axially outermost and is also referred to as shoulder land portion. The land portion positioned on the equator plane is also referred to as center land portion. In a case where no land portion is provided on the equator plane, the land portion closest to the equator plane is also referred to as center land portion. The center land portion and the shoulder land portion interpose a land portion also referred to as middle land portion.

[0200] The tread 4 includes five land portions 12 aligned axially. The five land portions 12 include the land portion 12 that is positioned axially outermost and is a shoulder land portion 22. The land portion 12 positioned on the equator plane is a center land portion 24. The center land portion 24 and the shoulder land portion 22 interpose the land portion 12 as a middle land portion 26.

[0201] Though not detailed, the land portions 12 have widths that are determined as appropriate in accordance with the specifications of the tire 2.

[0202] In the present disclosure, the plurality of land portions formed on the tread includes a land portion that is positioned between the circumferential grooves adjacent to each other and is also referred to as main land portion.

[0203] As shown in FIG. 2, the center land portion 24 of the tire 2 is positioned between two center circumferential

grooves 14. The middle land portion 26 is positioned between the center circumferential groove 14 and the shoulder circumferential groove 16. Each of the center land portion 24 and the middle land portion 26 is the land portion 12 disposed between the circumferential grooves 10 adjacent to each other.

[0204] On the tread 4, the center land portion 24 and the middle land portion 26 are main land portions 28. The five land portions 12 formed on the tread 4 include three main land portions 28 each positioned between the circumferential grooves 10 adjacent to each other.

[0205] The tread 4 of the tire 2 is provided with the plurality of land portions 12 aligned axially, and the plurality of land portions 12 includes a plurality of main land portions 28 each positioned between the circumferential grooves 10 adjacent to each other.

[0206] In the present disclosure, the plurality of main land portions includes main land portions that are positioned axially outermost and are also referred to as outer main land portions.

[0207] In the tire 2, the center land portion 24 and a pair of middle land portions 26 as the main land portions 28 include the main land portions 28 that are positioned axially outermost and are the middle land portions 26. The middle land portions 26 are outer main land portions 28s.

[0208] Left and right outer main land portions 28s interpose the main land portion 28 also referred to as inner main land portion 28u. On the tire 2, the center land portion 24 is the inner main land portion 28u. The inner main land portion 28u is provided on both sides thereof with the circumferential narrow grooves 18. The circumferential narrow grooves 18 adjacent to each other interpose the main land portion 28 that is the inner main land portion 28u.

[0209] The shoulder circumferential groove 16 is positioned axially outside the middle land portion 26. As described above, the shoulder circumferential groove 16 is the circumferential wide groove 20. The circumferential grooves 10 positioned axially outside the outer main land portions 28s are the circumferential wide grooves 20 larger in groove width than the circumferential narrow groove 18.

[0210] The shoulder land portion 22 is positioned axially outside the shoulder circumferential groove 16 and includes the end TE of the tread surface 6. The shoulder land portion 22 is positioned further outside the shoulder circumferential groove 16 that is positioned axially outermost. The shoulder land portion 22 is not the main land portion 28.

[0211] The tire 2 may be further provided with the land portion 12 positioned between the shoulder land portion 22 and the middle land portion 26. In this case, the land portion 12 positioned between the shoulder land portion 22 and the middle land portion 26 is provided on both sides with the circumferential grooves 10, and is thus the main land portion 28. The shoulder land portion 22 and the middle land portion 26 may further interpose a plurality of land portions 12.

[0212] On this tire 2, a plurality of lateral grooves 32 traversing the land portions 12 is carved in all the land portions 12 formed on the tread 4. Each of the land portions 12 is thus provided with a plurality of blocks 34 aligned circumferentially. The tire 2 has the tread pattern as a block pattern.

[0213] The lateral groove 32 carved in the center land portion 24 is also referred to as center lateral groove 36. The center lateral groove 36 connects between the center circumferential groove 14 (hereinafter, a first center circum-

ferential groove 141) adjacent to the first end TE1 of the tread surface 6 and the center circumferential groove 14 (hereinafter, a second center circumferential groove 142) adjacent to the second end TE2.

[0214] The block 34 formed in the center land portion 24 is also referred to as center block 38. A plurality of center lateral grooves 36 provides the center land portion 24 with a plurality of center blocks 38.

[0215] The lateral groove 32 carved in the middle land portion 26 is also referred to as middle lateral groove 40. The middle lateral groove 40 connects between the shoulder circumferential groove 16 and the center circumferential groove 14.

[0216] The block 34 formed in the middle land portion 26 is also referred to as middle block 42. A plurality of middle lateral grooves 40 provides the middle land portion 26 with a plurality of middle blocks 42.

[0217] The lateral groove 32 carved in the shoulder land portion 22 is also referred to as shoulder lateral groove 44. The shoulder lateral groove 44 connects between the end TE of the tread surface 6 and the outer peak 16s of the shoulder circumferential groove 16.

[0218] The block 34 formed in the shoulder land portion 22 is also referred to as shoulder block 46. A plurality of shoulder lateral grooves 44 provides the shoulder land portion 22 with a plurality of shoulder blocks 46.

[0219] The shoulder lateral groove 44 includes a deep bottom portion 44d adjacent to the shoulder circumferential groove 16 and a shallow bottom portion 44s adjacent to the end TE of the tread surface 6. The shallow bottom portion 44s includes a shoulder sipe 44p carved therein. The shoulder block 46 includes a shoulder narrow groove 46g carved therein to connect the deep bottom portion 44d as a former contact portion and the shallow bottom portion 44s as a latter contact portion.

[0220] In the present disclosure, the lateral groove 32 traversing the main land portion 28 is also referred to as main lateral groove 48.

[0221] As described above, the center land portion 24 and the middle land portion 26 are the main land portions 28. Accordingly, the center lateral grooves 36 carved in the center land portion 24 and the middle lateral grooves 40 carved in the middle land portion 26 are the main lateral grooves 48.

[0222] The tread 4 includes the plurality of main land portions 28 each of which includes the plurality of main lateral grooves 48 connecting the circumferential grooves 10 adjacent to each other.

[0223] The blocks 34 formed by carving the plurality of main lateral grooves 48 in the main land portion 28 are also referred to as main blocks 50.

[0224] The center blocks 38 formed by carving the center lateral grooves 36 in the center land portion 24 and the middle blocks 42 formed by carving the middle lateral grooves 40 in the middle land portions 26 are the main blocks 50.

[0225] The plurality of main lateral grooves 48 carved in the main land portion 28 provides the main land portion 28 with the plurality of main blocks 50 aligned circumferentially.

[0226] As described above, the plurality of main land portions 28 includes the outer main land portions 28s as the main land portions 28 positioned axially outermost and the

inner main land portion 28u as the main land portion 28 positioned between the left and right outer main land portions 28s.

[0227] The main lateral grooves 48 carved in the outer main land portions 28s are also referred to as outer main lateral grooves 78, and the main blocks 50 formed in the outer main land portions 28s are also referred to as outer main blocks 50s.

[0228] The main lateral grooves 48 carved in the inner main land portion 28u are also referred to as inner main lateral grooves 80, and the main blocks 50 formed in the inner main land portion 28u are also referred to as inner main blocks 50u.

[0229] As described above, the shoulder land portion 22 is not the main land portion 28. The shoulder lateral grooves 44 carved in the shoulder land portion 22 are not the main lateral grooves 48. The shoulder blocks 46 formed by carving the shoulder lateral grooves 44 in the shoulder land portion 22 are not the main blocks 50.

[0230] The main blocks 50 of the tire 2 are each provided with a transverse sipe 52 traversing the main block 50.

[0231] The transverse sipes 52 of the tire 2 are provided in the center blocks 38 and the middle blocks 42 as the main blocks 50. The transverse sipes 52 may alternatively be provided only in the center blocks 38. The transverse sipes 52 may still alternatively be provided only in the middle blocks 42. That is, in at least one of the main land portions 28 of the tire 2, each of the main blocks 50 includes the transverse sipe 52 traversing the main block 50.

[0232] FIG. 4 is a sectional view of the inner main lateral groove 80 taken along a line IV-IV in FIG. 2. FIG. 4 shows a section of the inner main lateral groove 80 along a plane perpendicular to a longitudinal direction of the inner main lateral groove 80. In the tire 2, the outer main lateral groove 78 is equal in sectional shape to the inner main lateral groove 80. Description is not made to the sectional shape of the outer main lateral groove 78.

[0233] FIG. 4 shows a sectional shape of the main lateral groove 48. The sectional shape of the main lateral groove 48 will be described with reference to FIG. 4.

[0234] The main lateral groove 48 includes a groove portion 82 and a sipe portion 84. The groove portion 82 includes a groove opening 48M of the main lateral groove 48. The groove portion 82 has a groove width not less than 1.0 mm. The groove portion 82 is not a sipe. The sipe portion 84 includes a groove bottom 48T of the main lateral groove 48. The sipe portion 84 is smaller in groove width than the groove portion 82. Specifically, the groove width of the sipe portion 84 is less than 1.0 mm. The sipe portion 84 is a sipe.

[0235] The groove portion 82 includes a tapered portion 86 and a body portion main body 88. The tapered portion 86 includes the groove opening 48M mentioned above. The tapered portion 86 is tapered inward from the groove opening 48M. The body portion main body 88 is positioned radially inside the tapered portion 86. The body portion main body 88 is provided continuously to the tapered portion 86. The body portion main body 88 and the tapered portion 86 have a boundary as a groove opening 88M of the body portion main body 88. The body portion main body 88 is tapered inward from the groove opening 88M. The body portion main body 88 includes a groove bottom 82T of the groove portion 82. The body portion main body 88 is larger in groove width than the sipe portion 84.

[0236] The groove portion 82 is not necessarily provided with the tapered portion 86. In this case, a section of the groove portion 82 is shaped such that a wall surface of the body portion main body 88 shown in FIG. 4 is expanded outward and an extension line of the wall surface and an extension line of the tread surface 6 intersect each other at the groove opening of the main lateral groove 48.

[0237] From the viewpoint that the tire 2 can effectively suppress a strain concentration to the edge of the main block 50 while ensuring groove capacity of the main lateral groove 48, the groove portion 82 of the main lateral groove 48 is preferably provided with the tapered portion 86 as shown in FIG. 4.

[0238] The sipe portion 84 is positioned radially inside the groove portion 82. The sipe portion 84 is carved in the groove bottom 82T of the groove portion 82. The sipe portion 84 extends further inward from the groove bottom 82T of the groove portion 82. The sipe portion 84 is shaped with use of a blade made of a flat plate. The sipe portion 84 has a planar wall surface.

[0239] FIG. 4 includes a double-pointed arrow MY indicating a length as a groove depth of the main lateral groove 48. FIG. 4 includes a double-pointed arrow MH indicating a length as a groove depth of the groove portion 82. FIG. 4 includes a double-pointed arrow MT indicating a length as a groove depth of the tapered portion 86.

[0240] The groove depth MY of the main lateral groove 48 is equal to the groove depth DGC of the circumferential groove 10, or the groove depth MY of the main lateral groove 48 is shallower than the groove depth DGC of the circumferential groove 10. Specifically, the groove depth MY of the main lateral groove is preferably not less than 0.80 times and not greater than 1.00 times the groove depth DGCs of the shoulder circumferential groove 16.

[0241] From the viewpoint that the tire 2 can effectively suppress a strain concentration to the edge of the main block 50 while ensuring the groove capacity of the main lateral groove 48, a ratio (MT/MY) of the groove depth MT of the tapered portion 86 to the groove depth MY of the main lateral groove 48 is preferably not less than 0.12 and not greater than 0.14.

[0242] FIG. 5 is a sectional view taken along a line V-V in FIG. 2, showing the center circumferential groove 14. FIG. 5 shows a section of the center circumferential groove 14 along a plane perpendicular to a longitudinal direction of the center circumferential groove 14.

[0243] As described above, the center circumferential groove 14 is the circumferential narrow groove 18. FIG. 5 shows a section of the circumferential narrow groove 18.

[0244] The circumferential narrow groove 18 includes a body portion 58 and an enlarged width portion 60. The body portion 58 includes a groove opening 18M of the circumferential narrow groove 18. The enlarged width portion 60 is positioned radially inside the body portion 58. The enlarged width portion 60 includes a groove bottom 18T of the circumferential narrow groove 18.

[0245] The body portion 58 of the tire 2 includes a tapered portion 62 and a body portion main body 64. The circumferential narrow groove 18 includes a portion at a groove opening 18M processed to be tapered.

[0246] The tapered portion 62 includes the groove opening 18M of the circumferential narrow groove 18. The tapered portion 62 is tapered inward from the groove opening 18M. The tapered portion 62 shown in FIG. 5 has a wall surface

having a contour indicated by a straight line. This contour may alternatively be indicated by a curved line.

[0247] FIG. 5 includes a double-pointed arrow WA indicating a length as a groove width at the groove opening 18M of the tapered portion 62. The groove width WA of the tapered portion 62 is preferably not less than 0.15 times and not greater than 0.45 times the groove width WGCs of the shoulder circumferential groove 16.

[0248] The body portion main body 64 is positioned radially inside the tapered portion 62. The body portion main body 64 is provided continuously to the tapered portion 62. The body portion main body 64 extends linearly in a depth direction of the circumferential narrow groove 18. In the section shown in FIG. 5, the body portion main body 64 has a wall surface having a contour indicated by a straight line. FIG. 5 includes a double-pointed arrow WD indicating a length as the minimum groove width of the body portion main body 64. The body portion main body 64 has the groove width WD constant in the depth direction of the circumferential narrow groove 18.

[0249] As described above, in the case where the portion at the groove opening 8M of the groove 8 is processed to be tapered, the groove width at the groove opening 8M of the groove 8 is represented based on the virtual edge obtained assuming that the groove opening is not processed to be tapered. The groove width at the groove opening 18M of the circumferential narrow groove 18 is indicated by the groove width WD of the body portion main body 64.

[0250] FIG. 5 includes a position PU indicating a boundary between the tapered portion 62 and the body portion main body 64. The boundary PU is indicated by an intersection point between a wall surface contour line of the tapered portion 62 and a wall surface contour line of the body portion main body 64. In a case where the boundary between the tapered portion 62 and the body portion main body 64 has a rounded portion as shown in FIG. 5, the boundary PU is indicated by an intersection point between an extension line of the wall surface contour line of the tapered portion 62 and an extension line of the wall surface contour line of the body portion main body 64.

[0251] The enlarged width portion 60 is positioned radially inside the body portion main body 64. The enlarged width portion 60 is provided continuously to the body portion main body 64. The enlarged width portion 60 has a groove width larger than the groove width WD of the body portion main body 64.

[0252] FIG. 5 includes a double-pointed arrow WN indicating a length as the maximum groove width of the enlarged width portion 60. The enlarged width portion 60 has the maximum groove width WN at a position PN (hereinafter, maximum groove width position PN). A portion excluding the body portion 58 of the circumferential narrow groove 18, that is, the enlarged width portion 60 of the circumferential narrow groove 18 is tapered outward from the maximum groove width position PN and is tapered inward from the maximum groove width position PN.

[0253] The enlarged width portion 60 includes the inflection portion 94 and the bottom portion 96. The inflection portion 94 is positioned radially inside the body portion main body 64. The bottom portion 96 is positioned radially inside the inflection portion 94.

[0254] The inflection portion 94 connects between the body portion main body 64 and the bottom portion 96. The inflection portion 94 has a groove width gradually increased

from the body portion main body **64** toward the bottom portion **96**. The inflection portion **94** is curved to be depressed inward from outside thereof. The inflection portion **94** of the tire **2** has a contour indicated by an arc. FIG. **5** includes an arrow R_c indicating a radius of the arc as the contour of the inflection portion **94**.

[0255] FIG. **5** includes a position PS indicating a boundary between the body portion main body **64** and the enlarged width portion **60**. As described above, in the section of the circumferential narrow groove **18**, the wall surface contour line of the body portion main body **64** is straight. In the present disclosure, the enlarged width portion **60** has a wall surface contour line that converges on the wall surface contour line of the body portion main body **64** at a position (in the circumferential narrow groove **18** shown in FIG. **5**, a boundary between the straight line indicating the contour of the body portion main body **64** and the arc indicating the contour of the inflection portion **94**) corresponding to the boundary PS between the body portion main body **64** and the enlarged width portion **60**. In a case where the boundary PS cannot be specified in accordance with a difference in contour, in the groove width from the body portion main body **64** to the enlarged width portion **60**, a position at which the circumferential narrow groove **18** has a groove width equal to 1.1 times the groove width WD of the body portion main body **64** is indicated as the boundary PS between the body portion main body **64** and the enlarged width portion **60**.

[0256] The bottom portion **96** includes the groove bottom **18T**. The bottom portion **96** has a rounded contour. The bottom portion **96** is curved to bulge outward from inside thereof. The bottom portion **96** of the circumferential narrow groove **18** shown in FIG. **5** has a contour indicated by an arc. FIG. **5** includes an arrow R_t indicating a radius of the arc as the contour of the bottom portion **96**. The radius R_t of the arc is exemplarily not less than 1.5 mm and not greater than 3.5 mm.

[0257] FIG. **5** includes a position PR indicating a boundary between the inflection portion **94** and the bottom portion **96**. The arc indicating the contour of the inflection portion **94** and the arc indicating the contour of the bottom portion **96** are in contact with each other on the boundary PR.

[0258] As shown in FIG. **5**, the bottom portion **96** includes the maximum groove width position PN of the enlarged width portion **60**. In other words, the maximum groove width position PN is positioned radially inside the boundary PR. The maximum groove width WN of the enlarged width portion **60** is equal to twice the radius R_t of the arc indicating the contour of the bottom portion **96**.

[0259] In the tire **2**, the radius R_c of the arc indicating the contour of the inflection portion **94** is larger than the radius R_t of the arc indicating the contour of the bottom portion **96**. The circumferential narrow groove **18** can thus sufficiently exhibit its function. From this viewpoint, a ratio R_c/R_t of the radius R_c of the arc indicating the contour of the inflection portion **94** to the radius R_t of the arc indicating the contour of the bottom portion **96** is preferably not less than 1.5 and not greater than 20.

[0260] The ratio R_c/R_t set to be not less than 1.5 can suppress uneven wear due to a rapid change in the stiffness of the tire **2**. The ratio R_c/R_t is more preferably not less than 2.0 from this viewpoint.

[0261] The ratio R_c/R_t set to be not greater than 20 can suppress a decrease in the wet performance of the tire **2**. The ratio R_c/R_t is more preferably not greater than 15 from this viewpoint.

[0262] As described above, the groove width of the enlarged width portion **60** is larger than the groove width WD of the body portion main body **64**. From the viewpoint of maintaining wet performance, the maximum groove width WN of the enlarged width portion **60** is preferably not less than twice the minimum groove width WD of the body portion main body **64**, and is more preferably not less than three times. From the viewpoint that an impact is suppressed on stiffness of the crown portion of the tread **4** and the tire **2** can maintain excellent uneven wear resistance, the maximum groove width WN of the enlarged width portion **60** is preferably not greater than eight times the minimum groove width WD of the body portion main body **64**, and is more preferably not greater than seven times.

[0263] The circumferential narrow groove **18** is not necessarily provided with the tapered portion **62**. In other words, the body portion **58** may be formed only by the body portion main body **64**. In this case, the section of the circumferential narrow groove **18** is shaped such that the wall surface of the body portion main body **64** shown in FIG. **5** is extended outward and an extension line of the wall surface and an extension line of the tread surface **6** intersect each other at a groove opening of the body portion main body **64**, that is, the groove opening **18M** of the circumferential narrow groove **18**.

[0264] From the viewpoint that the tire **2** can effectively suppress a strain concentration to an edge of the main block **50** while ensuring groove capacity of the circumferential narrow groove **18**, the circumferential narrow groove **18** is preferably provided with the tapered portion **62** as shown in FIG. **5**.

[0265] FIG. **5** includes a double-pointed arrow HM indicating a length as a groove depth of the circumferential narrow groove **18**. FIG. **5** includes a double-pointed arrow HH indicating a length as a groove depth of the body portion **58**. FIG. **5** includes a double-pointed arrow HT indicating a length as a groove depth of the tapered portion **62**.

[0266] The groove depth HM of the circumferential narrow groove **18** of the tire **2** is substantially equal to the groove depth DGC of the circumferential groove **10**. Specifically, the groove depth HM of the circumferential narrow groove **18** is not less than 0.95 times and not greater than 1.05 times the groove depth DGCs of the shoulder circumferential groove **16**.

[0267] FIG. **5** includes a position PB indicating a width reference position of the circumferential narrow groove **18**. The circumferential narrow groove **18** includes the width reference position PB between the body portion main body **64** and the position PN at which the enlarged width portion **60** has the maximum groove width WN. The circumferential narrow groove **18**, that is, the enlarged width portion **60** has a groove width WB equal to 2.0 times the minimum groove width WD of the body portion main body **64** at the width reference position PB. That is, the width reference position PB is the position at which the enlarged width portion **60** has the groove width WB equal to 2.0 times the minimum groove width WD of the body portion main body **64** between the body portion main body **64** and the position PN at which the enlarged width portion **60** has the maximum groove depth WN between the body portion main body **64** and the

position PN at which the enlarged width portion 60 has the maximum groove width WN. When an exposed position of the circumferential narrow groove 18 passes through the width reference position PB, the enlarged width portion 60 of the circumferential narrow groove 18 can effectively contribute to suppressing a decrease in wet performance.

[0268] FIG. 5 includes a double-pointed arrow HB indicating a length as a groove depth from the groove opening 18M of the circumferential narrow groove 18 to the width reference position PB.

[0269] From the viewpoint that the tire 2 can effectively suppress a strain concentration to the edge of the main block 50 while ensuring the groove capacity of the circumferential narrow groove 18, a ratio (HT/HM) of the groove depth HT of the tapered portion 62 to the groove depth HM of the circumferential narrow groove 18 is preferably not less than 0.12 and not greater than 0.14.

[0270] As described above, the circumferential narrow groove 18 of the tire 2 includes the body portion main body 64 having the narrow groove width WD. The tread 4 is deformed when the tread surface 6 comes into contact with a road surface. The groove width WD of the body portion main body 64 is adjusted such that facing wall surfaces 18W of the circumferential narrow groove 18 are brought into contact with each other at the body portion main body 64 by deformation of the tread 4. The tread 4 is deformed to bring facing wall surfaces 18W of the circumferential narrow groove 18 into contact with each other at the body portion main body 64.

[0271] The circumferential narrow groove 18 is formed between the center land portion 24 and the middle land portion 26. As described above, the circumferential narrow groove 18 is the circumferential groove 10, and the center land portion 24 and the middle land portion 26 are the main land portions 28. In the tire 2, the circumferential groove 10 positioned between the main land portions 28 adjacent to each other is the circumferential narrow groove 18.

[0272] When the tread surface 6 comes into contact with a road surface and the tread 4 is deformed, the facing wall surfaces 18W of the circumferential narrow groove 18 come into contact with each other at the body portion main body 64. The facing wall surfaces 18W of the circumferential narrow groove 18 are brought into contact with each other at the body portion main body 64 by deformation of the tread 4. The main land portions 28 (specifically main blocks 50) positioned on the both sides of the circumferential narrow groove 18 support each other. This suppresses deformation of the tread 4. The circumferential narrow groove 18 can contribute to reduction in rolling resistance. Meanwhile, the tread 4 is increased in apparent stiffness and may thus be decreased in wet performance. However, the groove portion 82 of the main lateral groove 48 suppresses the decrease in wet performance. At an initial stage of wear, it is inferred that the tire 2 can suppress a decrease in wet performance due to wear while reducing rolling resistance in this manner.

[0273] As the tread 4 gradually wears, the circumferential grooves 10 and the like are decreased in groove capacity. This may cause a decrease in wet performance. However, the enlarged width portion 60 larger in groove width than the body portion main body 64 is positioned radially inside the body portion 58 of the circumferential narrow groove 18. Furthermore, the sipe portion 84 smaller in groove width than the groove portion 82 is positioned radially inside the groove portion 82 of the main lateral groove 48. In the

circumferential narrow groove 18, the enlarged width portion 60 is exposed after the body portion main body 64 disappears. In the main lateral groove 48, the sipe portion 84 is exposed after the groove portion 82 disappears. The enlarged width portion 60 and the sipe portion 84 can contribute to suppressing a decrease in wet performance.

[0274] In the tire 2, the groove depth MH of the groove portion 82 is smaller than the groove depth HB from the groove opening 18M of the circumferential narrow groove 18 to the width reference position PB. This avoids simultaneous exposure of the sipe portion 84 and the portion having a groove width larger than 2.0 times the minimum groove width of the body portion main body 64. This suppresses uneven wear due to a rapid change in pattern. Each of the main lateral groove 48 and the circumferential narrow groove 18 can stably exhibit its function.

[0275] Wear decreases volume of the tread 4. The portion having a groove width larger than 2.0 times the minimum groove width of the body portion main body 64 is exposed after the sipe portion 84 is exposed. However, the tread 4 is decreased in deformation allowance and is thus increased in apparent stiffness. The increase in stiffness can contribute to reduction in rolling resistance.

[0276] The increase in stiffness advantageously affects rolling resistance but disadvantageously affects wet performance. However, the rubber composition forming the tread 4 of the tire 2 contains a styrene butadiene rubber and silica. This increases a glass transition temperature (T_g) of the rubber component as well as improves a road surface following property in a micro-deformation region. The tread 4 of the tire 2 can contribute to improvement of wet performance regardless of the stage of wear. In particular, the amount CSB of the styrene butadiene rubber, the amount BS of the silica, the groove depth MH of the groove portion 82, and the groove depth HB from the groove opening 18M of the circumferential narrow groove 18 to the width reference position PB are set to satisfy the above relational expression. Accordingly, the styrene butadiene rubber and the silica synergistically suppress a decrease in wet performance also at the middle stage of wear from exposure of the sipe portion 84 of the main lateral groove 48 to exposure of the width reference position PB of the enlarged width portion 60 in the circumferential narrow groove 18.

[0277] The tire 2 can suppress a decrease in wet performance while maintaining low rolling resistance from the start of use until the tire needs to be replaced.

[0278] The tire 2 can suppress a decrease in wet performance due to wear while reducing rolling resistance.

[0279] As described above, the groove depth MH of the groove portion 82 is smaller than the groove depth HB from the groove opening 18M of the circumferential narrow groove 18 to the width reference position PB. In other words, the groove depth HB from the groove opening 18M of the circumferential narrow groove 18 to the width reference position PB is larger than the groove depth MH of the groove portion 82. Specifically, the groove depth HB (mm) from the groove opening 18M of the circumferential narrow groove 18 to the width reference position PB and the groove depth MH (mm) of the groove portion 82 preferably satisfy the following relational expression.

$$0 < (HB - MH) \leq 5.0$$

[0280] The width reference position PB of the enlarged width portion 60 in the circumferential narrow groove 18 is exposed at appropriate timing after the groove portion 82 of the main lateral groove 48 disappears. This suppresses uneven wear due to a rapid change in pattern. Each of the main lateral groove 48 and the circumferential narrow groove 18 can stably exhibit its function. From this viewpoint, the groove depth HB (mm) from the groove opening 18M of the circumferential narrow groove 18 to the width reference position PB and the groove depth MH (mm) of the groove portion 82 more preferably satisfy the following relational expression,

$$1.0 \leq (HB - MH) \leq 4.0.$$

[0281] The land ratio of the tire 2 is preferably not less than 75%. In this case, the land portions 12 are likely to support each other to effectively increase stiffness of the tread 4. The tire 2 can be effectively reduced in rolling resistance as well as can be improved in wear resistance. As described above, the rubber composition of the tread 4 contains silica as a filler. This may decrease stiffness of the tread 4 in comparison to a case where the filler contains only carbon black. However, when the land ratio is set to be not less than 75%, the tread 4 can maintain stiffness at the required degree. In the tire 2, the circumferential narrow groove 18 and the main lateral groove 48 can sufficiently exhibit functions thereof. The tire 2 can suppress a decrease in wet performance due to wear while reducing rolling resistance. The land ratio is more preferably not less than 78% from this viewpoint. The land ratio is preferably not greater than 90% from the viewpoint of maintaining excellent wet performance.

[0282] A ratio (HH/HM) of the groove depth HH of the body portion 58 to the groove depth HM of the circumferential narrow groove 18 is preferably not less than 0.30 and not greater than 0.70.

[0283] When the ratio (HH/HM) is set to be not less than 0.30, the tire 2 can effectively suppress an impact of the enlarged width portion 60 on stiffness of the main block 50. The tire 2 can progress wear of the tread 4 while maintaining stiffness of the main block 50. The tire 2 can maintain excellent uneven wear resistance. The ratio (HH/HM) is more preferably not less than 0.35 from this viewpoint.

[0284] The ratio (HH/HM) set to be not greater than 0.70 achieves exposure of the width reference position PB of the enlarged width portion 60 in the circumferential narrow groove 18 at appropriate timing after exposure of the sipe portion 84 of the main lateral groove 48. Also in this case, the tire 2 can progress wear of the tread 4 while maintaining stiffness of the main block 50 so as to maintain excellent uneven wear resistance. The ratio (HH/HM) is more preferably not greater than 0.65 from this viewpoint.

[0285] A ratio (MH/HM) of the groove depth MH of the groove portion 82 of the main lateral groove 48 to the groove depth HM of the circumferential narrow groove 18 is preferably not less than 0.30 and not greater than 0.60.

[0286] When the ratio (MH/HM) is set to be not less than 0.30, the tire 2 can achieve disappearance of the groove portion 82 at appropriate timing. The tire 2 can maintain excellent outer appearance quality and excellent traction performance. The ratio (MH/HM) is more preferably not less than 0.35 from this viewpoint.

[0287] When the ratio (MH/HM) is set to be not greater than 0.60, the tire 2 can effectively suppress an impact of the groove portion 82 on stiffness of the main block 50. The tire 2 can progress wear of the tread 4 while maintaining stiffness of the main block 50. The tire 2 can effectively suppress wear in the center portion and can thus maintain excellent uneven wear resistance. The ratio (MH/HM) is more preferably not greater than 0.55 from this viewpoint.

[0288] The body portion main body 64 of the circumferential narrow groove 18 has the groove width WD smaller than the groove width WGCs at the groove opening of the shoulder circumferential groove 16. As described above, when the tire 2 comes into contact with a road surface, the pair of wall surfaces 18W of the circumferential narrow groove 18 come into contact with each other at the body portion main body 64. The main land portions 28 disposed adjacent to each other and interposing the circumferential narrow groove 18 support each other. The main land portions 28 are formed in the crown portion of the tread portion. The main land portions 28 disposed adjacent to each other and supporting each other increase apparent stiffness of the crown portion to suppress deformation of the crown portion. The tire 2 can effectively suppress wear at the crown portion. The tire 2 can be improved in uneven wear resistance.

[0289] From this viewpoint, a ratio (WD/WGCs) of the groove width WD of the body portion main body 64 of the circumferential narrow groove 18 to the groove width WGCs of the shoulder circumferential groove 16 is preferably not greater than 0.35 and is more preferably not greater than 0.20.

[0290] From the viewpoint that the circumferential narrow groove 18 can contribute to drainability and the tire 2 can maintain excellent wet performance, the ratio (WD/WGCs) is preferably not less than 0.01 and is more preferably not less than 0.05.

[0291] FIG. 5 includes a double-pointed arrow HN indicating a length as a groove depth from the groove opening 18M of the circumferential narrow groove 18 to the maximum groove width position PN.

[0292] From the viewpoint that the enlarged width portion 60 can effectively contribute to suppression of a decrease in wet performance, a ratio (HN/HM) of the groove depth HN from the groove opening 18M of the circumferential narrow groove 18 to the maximum groove width position PN to the groove depth HM of the circumferential narrow groove 18 is preferably not less than 0.75 and not greater than 0.95.

[0293] As shown in FIG. 2, the circumferential narrow grooves 18 circumferentially extend not linearly but while meandering. In particular, the circumferential narrow grooves 18 of the tire 2 include first narrow grooves 66 close to the first end TE of the tread surface 6, second narrow grooves 68 close to the second end TE2 of the tread surface 6, and connection narrow grooves 70 connecting the first narrow groove 66 and the second narrow groove 68.

[0294] The connection narrow grooves 70 include the connection narrow groove 70 also referred to as first connection narrow groove 70a connecting the first narrow groove 66 positioned adjacent to the former contact portion

and the second narrow groove **68** positioned adjacent to the latter contact portion. The connection narrow grooves **70** include the connection narrow groove **70** also referred to as second connection narrow groove **70b** connecting the second narrow groove **68** positioned adjacent to the former contact portion and the first narrow groove **66** positioned adjacent to the latter contact portion.

[0295] Assuming that each unit referred to as groove unit includes the first narrow groove **66**, the first connection narrow groove **70a**, the second narrow groove **68**, and the second connection narrow groove **70b** connected in the mentioned order, the circumferential narrow groove **18** is formed by circumferentially connecting a plurality of groove units. The first narrow grooves **66** and the second narrow grooves **68** are alternately disposed circumferentially.

[0296] When the tread surface **6** comes into contact with a road surface and the tread **4** is deformed, the facing wall surfaces **18W** of the circumferential narrow groove **18** come into contact with each other at the body portion main body **64**. The circumferential narrow groove **18** circumferentially extends while meandering, and the wall surfaces are thus effectively engaged with each other. The main land portions **28** positioned on the both sides of the circumferential narrow groove **18** restrain each other. The main land portions **28** are increased in apparent stiffness. This effectively suppresses deformation of the main land portions **28**. The tire **2** can be effectively reduced in rolling resistance as well as can be improved in wear resistance. As described above, the rubber composition of the tread **4** contains silica as a filler. The tread may thus be decreased in stiffness in comparison to the case where the filler contains only carbon black. However, the circumferential narrow groove **18** includes the first narrow grooves **66**, the second narrow grooves **68**, and the connection narrow grooves **70** and the first narrow grooves **66** and the second narrow grooves **68** are alternately disposed circumferentially so as to maintain stiffness of the tread **4** at the required degree. From this viewpoint, preferably, the circumferential narrow groove **18** includes the first narrow grooves **66**, the second narrow grooves **68**, and the connection narrow grooves **70** each connecting the first narrow groove **66** and the second narrow groove **68**, and the first narrow grooves **66** and the second narrow grooves **68** are alternately disposed circumferentially.

[0297] The tire **2** includes a pair of center circumferential grooves **14** disposed to interpose the equator plane, that is, the first center circumferential groove **141** and the second center circumferential groove **142**.

[0298] As described above, the center circumferential groove **14** of the tire **2** is the circumferential narrow groove **18**.

[0299] The first center circumferential groove **141** is a first circumferential narrow groove **181**, whereas the second center circumferential groove **142** is a second circumferential narrow groove **182**.

[0300] The first narrow grooves **66** and the second narrow grooves **68** in the circumferential narrow groove **18** extend circumferentially. The first narrow grooves **66** and the second narrow grooves **68** have constant circumferential lengths.

[0301] The second narrow grooves **68** in the second circumferential narrow groove **182** are equal in length to the first narrow grooves **66** in the first circumferential narrow groove, whereas the first narrow grooves **66** in the second

circumferential narrow groove **182** are equal in length to the second narrow grooves **68** in the first circumferential narrow groove **181**.

[0302] The first narrow grooves **66** in the first circumferential narrow groove **181** and the second narrow grooves **68** in the second circumferential narrow groove **182** are positioned adjacent to the ends TE of the tread surface **6**, whereas the second narrow grooves **68** in the first circumferential narrow groove **181** and the first narrow grooves **66** in the second circumferential narrow groove **182** are positioned adjacent to the equator plane.

[0303] Hereinafter for convenient description, the second narrow grooves **68** in the first circumferential narrow groove **181** and the first narrow grooves **66** in the second circumferential narrow groove **182** are referred to as inner narrow grooves **72**, whereas the first narrow grooves **66** in the first circumferential narrow groove **181** and the second narrow grooves **68** in the second circumferential narrow groove **182** are referred to as outer narrow grooves **74**. The first connection narrow grooves **70a** in the first circumferential narrow groove **181** and the second connection narrow grooves **70b** in the second circumferential narrow groove **182** are referred to as outer connection grooves **76s**. Each of the outer connection grooves **76s** connects the outer narrow groove **74** adjacent to the former contact portion and the inner narrow groove **72** adjacent to the latter contact portion. The second connection narrow grooves **70b** in the first circumferential narrow groove **181** and the first connection narrow grooves **70a** in the second circumferential narrow groove **182** are referred to as inner connection grooves **76u**. Each of the inner connection grooves **76u** connects the inner narrow groove **72** adjacent to the former contact portion and the outer narrow groove **74** adjacent to the latter contact portion.

[0304] The inner narrow grooves **72** (hereinafter, first inner narrow grooves **721**) in the first circumferential narrow groove **181** are positioned closer to the latter contact portion than the inner narrow grooves **72** (hereinafter, second inner narrow grooves **722**) in the second circumferential narrow groove **182**. Part of the first inner narrow grooves **721** and the second inner narrow grooves **722** are axially overlapped with each other.

[0305] The outer narrow grooves **74** (hereinafter, first outer narrow grooves **741**) in the first circumferential narrow groove **181** are positioned closer to the latter contact portion than the outer narrow grooves **74** (hereinafter, second outer narrow grooves **742**) in the second circumferential narrow groove **182**. Part of the first outer narrow grooves **741** and the second outer narrow grooves **742** are axially overlapped with each other.

[0306] FIG. 1 includes a double-pointed arrow LS indicating a length as a circumferential length of the inner narrow groove **72**. FIG. 1 includes a double-pointed arrow LL indicating a length as a circumferential length of the outer narrow groove **74**. The outer narrow grooves **74** are longer than the inner narrow grooves **72** in the tire **2**. Specifically, the circumferential length LL of the outer narrow grooves **74** is preferably not less than 1.1 times and not greater than 1.5 times the circumferential length LS of the inner narrow grooves **72**.

[0307] The first circumferential narrow groove **181** and the second circumferential narrow groove **182** are close to each other where the first inner narrow groove **721** and the second inner narrow groove **722** face each other, and are far

from each other where the first outer narrow groove **741** and the second outer narrow groove **742** face each other.

[0308] The first circumferential narrow groove **181** and the second circumferential narrow groove **182** have an axial distance varied in the circumferential direction. The axial distance is short between the first inner narrow groove **721** and the second inner narrow groove **722**, and is long between the first outer narrow groove **741** and the second outer narrow groove **742**.

[0309] The inner main lateral groove **80** carved in the inner main land portion **28u** connects the first inner narrow groove **721** and the second inner narrow groove **722** having the short axial distance. The inner main lateral groove **80** is disposed where the circumferential narrow grooves **18** adjacent to each other are close to each other.

[0310] As described above, the first outer narrow groove **741** is positioned closer to the latter contact portion than the second outer narrow groove **742**. The inner main lateral groove **80** positioned adjacent to the first end TE1 of the tread surface **6** has an end positioned closer to the latter contact portion than another end of the inner main lateral groove **80** positioned adjacent to the second end TE2. In other words, the inner main lateral groove **80** is inclined relative to the axial direction.

[0311] The inner main block **50u** formed between the first circumferential narrow groove **181** and the second circumferential narrow groove **182** is positioned circumferentially between the inner main lateral groove **80** adjacent to the former contact portion and the inner main lateral groove **80** adjacent to the latter contact portion, and is positioned axially between the first outer narrow groove **741** and the second outer narrow groove **742**. Furthermore, the outer narrow grooves **74** are longer than the inner narrow grooves **72**, and the axial distance between the first outer narrow groove **741** and the second outer narrow groove **742** is longer than the axial distance between the first inner narrow groove **721** and the second inner narrow groove **722**.

[0312] The inner main block **50u** formed between the circumferential narrow grooves **18** adjacent to each other is surrounded with two inner main lateral grooves **80** disposed where the circumferential narrow grooves **18** adjacent to each other are close to each other, and two outer narrow grooves **74** each of which is an element of the circumferential narrow groove **18**. The inner main block **50u** has a shape like an octagon. The tire **2** can suppress an increase in ground-contact pressure at an edge of the inner main block **50u**. The tire **2** can be improved in uneven wear resistance. From this viewpoint, the inner main lateral groove **80** extending between the circumferential narrow grooves **18** adjacent to each other is preferably disposed where the circumferential narrow grooves **18** adjacent to each other are close to each other.

[0313] The inner peaks **16u** of the shoulder circumferential groove **16** as the circumferential wide groove **20** include first inner peaks **16uu** axially overlapped with the inner narrow grooves **72** of the circumferential narrow groove **18** and second inner peaks **16us** axially overlapped with the outer narrow grooves **74**. The first inner peaks **16uu** and the second inner peaks **16us** are alternately disposed circumferentially such that the first inner peak **16uu** and the second inner peak **16us** interpose the outer peak **16s**.

[0314] The outer peaks **16s** of the shoulder circumferential groove **16** include first outer peaks **16sa** overlapped with the shoulder lateral grooves **44** and second outer peaks **16sb**

overlapped with the shoulder blocks **46**. The first outer peaks **16sa** and the second outer peaks **16sb** are alternately disposed circumferentially such that the first outer peak **16sa** and the second outer peak **16sb** interpose the inner peak **16u**.

[0315] Single amplitude of the circumferential narrow groove **18** corresponds to double amplitude of the shoulder circumferential groove **16**, that is, the circumferential wide groove **20**. When the tire **2** travels on a wet road surface, water is likely to flow in the circumferential wide grooves **20**. The circumferential wide grooves **20** can contribute to improvement in wet performance.

[0316] The circumferential wide groove **20** and the circumferential narrow groove **18** have an axial distance varied in the circumferential direction. The axial distance from the circumferential wide groove **20** adjacent to the first end TE1 of the tread surface **6** is short between the second inner peak **16us** and the outer narrow groove **74** and is long between the first outer peak **16sa** and the inner narrow groove **72**. The axial distance from the circumferential wide groove **20** adjacent to the second end TE2 of the tread surface **6** is short between the second inner peak **16us** and the outer narrow groove **74** and is long between the second outer peak **16sb** and the inner narrow groove **72**.

[0317] The outer main lateral groove **78** carved in the outer main land portion **28s** connects the second inner peak **16us** of the circumferential wide groove **20** and the outer narrow groove **74** having the short axial distance. The outer main lateral groove **78** is disposed where the circumferential wide groove **20** and the circumferential narrow groove **18** are close to each other.

[0318] As shown in FIG. 2, the outer main lateral groove **78** is axially inclined in the outer main land portion **28s**. The outer main lateral groove **78** has an axially inner end positioned closer to the former contact portion than an axially outer end. When the tire **2** travels, the axially inner end of the outer main lateral groove **78** comes into contact with a road surface prior to the axially outer end. The outer main lateral groove **78** extends axially outward from the axially inner end. When the tire **2** travels on a wet road surface, the outer main lateral groove **78** can effectively drain water between the tire **2** and the road surface from a ground-contact surface. The tire **2** can be improved in wet performance. From this viewpoint, in the outer main land portion **28s**, preferably, the outer main lateral groove **78** is inclined relative to the axial direction, and the axially inner end of the outer main lateral groove **78** comes into contact with the road surface prior to the axially outer end.

[0319] FIG. 6 is a sectional view taken along a line VI-VI in FIG. 2. FIG. 6 shows a section of the transverse sipe **52**. FIG. 6 shows the section of the transverse sipe **52** along a plane perpendicular to a longitudinal direction of the transverse sipe **52**.

[0320] FIG. 6 shows the section of the transverse sipe **52** provided in the center block **38**. As described above, the transverse sipes **52** are provided also in the middle blocks **42**.

[0321] The transverse sipes **52** in the middle blocks **42** may be equal in sectional shape to or different from the transverse sipes **52** in the center blocks **38**.

[0322] The transverse sipes **52** in the middle blocks **42** shown in FIG. 2 are equal in sectional shape to the transverse sipes **52** in the center blocks **38**. Description is not made to the sectional shape of the transverse sipes **52** in the middle blocks **42**.

[0323] The transverse sipe 52 includes a sipe body 54 and a tubular portion 56. The sipe body 54 includes a groove opening 52M of the transverse sipe 52. The tubular portion 56 includes a groove bottom 52T of the transverse sipe 52.

[0324] The tubular portion 56 is positioned radially inside the sipe body 54. The tubular portion 56 extends in the longitudinal direction of the transverse sipe 52.

[0325] The sipe body 54 extends in a zigzag manner in the longitudinal direction of the transverse sipe 52 as shown in FIG. 2, and extends in a zigzag manner in a depth direction of the transverse sipe 52 as shown in FIG. 6. The sipe body 54 is a three-dimensional sipe. As shown in FIG. 7, the sipe body 54 may be a two-dimensional sipe expanding like a flat plate. In this case, the sipe body 54 extends linearly in a longitudinal direction and extends linearly in a depth direction.

[0326] FIG. 6 includes a solid line LM indicating a boundary between the sipe body 54 and the tubular portion 56. FIG. 4 also includes a double pointed arrow WM indicating a length as a groove width of the transverse sipe 52 measured along the boundary LM. The boundary LM is positioned such that the groove width WM is 1.0 mm.

[0327] The transverse sipe 52 includes the groove opening 52M having a groove width W_p less than 1.0 mm. A portion outside the boundary LM, that is, the sipe body 54 has a groove width less than 1.0 mm. The sipe body 54 is a sipe. A portion inside the boundary LM, that is, the tubular portion 56 has a groove width not less than 1.0 mm. The tubular portion 56 is larger in groove width than the sipe body 54.

[0328] The tubular portion 56 extends inward from a position on the boundary LM. FIG. 6 includes a double-pointed arrow WT indicating a length as the maximum groove width of the tubular portion 56. The tubular portion 56 has the maximum groove width WT at a position PT. The tubular portion 56 is tapered outward from a portion having the maximum groove width WT. The tubular portion 56 is tapered inward from the portion having the maximum groove width WT.

[0329] The tubular portion 56 has a sectional shape that may be circular or elliptical. The sectional shape may be a shape indicated by a straight line at the portion having the maximum groove width WT and arcs at a portion adjacent to the sipe body 54 and a portion adjacent to the groove bottom 52T, the portions interposing the portion indicated by the straight line (this shape is also referred to as track shape hereinafter).

[0330] The sipe body 54 can function as an edge component. The sipe body 54 can contribute to suppressing a decrease in wet performance at the initial stage of wear. The tubular portion 56 suppresses a decrease in groove capacity due to wear. The tubular portion 56 can contribute to suppressing a decrease in wet performance after the sipe body 54 disappears. From this viewpoint, preferably, each of the main blocks 50 provided in the tread 4 includes the transverse sipe 52 traversing the main block 50, the transverse sipe 52 includes the sipe body 54 and the tubular portion 56 positioned radially inside the sipe body 54, and the tubular portion 56 is larger in groove width than the sipe body 54.

[0331] FIG. 6 includes a position PG indicating a radially outer end of the tubular portion 56. FIG. 6 includes a position PA indicating a radially inner end of the tubular

portion 56. The radially inner end PA corresponds to the groove bottom 52T of the transverse sipe 52.

[0332] The pattern is largely changed in configuration after disappearance of the groove portion 82 until exposure of the portion having a groove width larger than 2.0 times the minimum groove width WD of the body portion main body 64 of the circumferential narrow groove 18. This period may have a decrease in wet performance.

[0333] As shown in FIG. 8, the width reference position PB of the circumferential narrow groove 18 is positioned between the radially outer end PG and the radially inner end PA of the tubular portion 56 in the tire 2. The tubular portion 56 is exposed while the pattern is largely changed in configuration. The tubular portion 56 thus exposed can contribute to suppressing a decrease in wet performance. The tire 2 can maintain excellent wet performance also while the pattern is largely changed in configuration. For convenient description, a two-dot chain line LT indicates a position of the groove bottom 82T of the groove portion 82 of the lateral groove 48.

[0334] As shown in FIG. 9, the transverse sipe 52 may be formed such that the groove bottom 82T of the groove portion 82 of the main lateral groove 48 is positioned between the radially outer end PG and the radially inner end PA of the tubular portion 56. The tubular portion 56 thus exposed can contribute to suppressing a decrease in wet performance also in this case. The tire 2 can thus maintain excellent wet performance also while the pattern is largely changed in configuration.

[0335] As shown in FIG. 10, the transverse sipe 52 may be formed such that both the width reference position PB of the circumferential narrow groove 18 and the groove bottom 82T of the groove portion 82 of the main lateral groove 48 are positioned between the radially outer end PG and the radially inner end PA of the tubular portion 56. The tubular portion 56 thus exposed can contribute to suppressing a decrease in wet performance also in this case. The tire 2 can thus maintain excellent wet performance also while the pattern is largely changed in configuration.

[0336] From the viewpoint that the tire 2 can maintain excellent wet performance also while the pattern is largely changed in configuration, the groove bottom 82T of the groove portion 82 of the main lateral groove 48, the width reference position PB of the circumferential narrow groove 18, or both the groove bottom 82T of the groove portion 82 of the main lateral groove 48 and the width reference position PB of the circumferential narrow groove 18 are preferably positioned between the radially outer end PG and the radially inner end PA of the tubular portion 56.

[0337] As described above, the center land portion 24 of the tire 2 is the inner main land portion 28u. As shown in FIG. 2, the inner main land portion 28u is positioned between two circumferential narrow grooves 18 adjacent to each other. The plurality of main land portions 28 provided on the tread 4 of the tire 2 includes the inner main land portion 28u positioned between the circumferential narrow grooves 18 adjacent to each other. The inner main land portion 28u includes a plurality of inner main blocks 50u.

[0338] Each of the inner main blocks 50u includes the transverse sipe 52. The sipe body 54 of the transverse sipe 52 is a three-dimensional sipe. The sipe body 54 may alternatively be a two-dimensional sipe.

[0339] While the tire 2 is travelling, the sipe body 54 has wall surfaces that are in contact with each other to support

each other. When the tread 4 is deformed and the wall surfaces of the sipe body 54 as the three-dimensional sipe come into tight contact with each other, the wall surfaces restrain each other so as to effectively increase stiffness of the tread 4. The tire 2 can be effectively reduced in rolling resistance as well as can be improved in wear resistance. As described above, the rubber composition of the tread 4 contains silica as a filler. This may decrease stiffness of the tread 4 in comparison to a case where the filler contains only carbon black. However, in a case where the sipe body 54 is formed as the three-dimensional sipe extending in a zigzag manner in the longitudinal direction and the depth direction, the tread 4 can maintain stiffness at the required degree. From this viewpoint, the sipe body 54 of the transverse sipe 52 preferably extends in a zigzag manner in the longitudinal direction and the depth direction.

[0340] In the tire 2, the sipe body 54 of the transverse sipe 52 included in the main block 50 of the outer main land portion 28s also extends in a zigzag manner in the longitudinal direction and the depth direction. Also in the outer main land portion 28s, when the tread 4 is deformed and the wall surfaces of the sipe body 54 come into tight contact with each other, the wall surfaces restrain each other so as to effectively increase stiffness of the tread 4. While maintaining wet performance, the tire 2 can be effectively reduced in rolling resistance as well as can be improved in wear resistance. From this viewpoint, the sipe body 54 of the transverse sipe 52 included in the main block 50 of the outer main land portion 28s in addition to the inner main land portion 28u, that is, the sipe body 54 of the transverse sipe 52 included in the main block 50 provided in each of the inner main land portion 28u and the outer main land portion 28s more preferably extends in a zigzag manner in the longitudinal direction and the depth direction.

[0341] FIG. 6 includes a double pointed arrow DA indicating a length as a groove depth of the transverse sipe 52. FIG. 6 also includes a double-pointed arrow DC indicating a length as a groove depth of the sipe body 54.

[0342] In the tire 2, the groove depth DA of the transverse sipe 52 is equal to the groove depth DGC of the circumferential groove 10, or the groove depth DA of the transverse sipe 52 is shallower than the groove depth DGC of the circumferential groove 10. Specifically, the groove depth DA of the transverse sipe 52 is not less than 0.80 times and not greater than 1.00 times a groove depth DGCs of the shoulder circumferential groove 16 as the circumferential wide groove 20.

[0343] A ratio (DC/DA) of the groove depth DC of the sipe body 54 of the transverse sipe 52 to the groove depth DA of the transverse sipe 52 is preferably not less than 0.35 and not greater than 0.80.

[0344] When the ratio (DC/DA) is set to be not less than 0.35, the tire 2 can achieve exposure of the tubular portion 56 at appropriate timing. The tire 2 can progress wear of the tread 4 while maintaining stiffness of the main block 50. The tire 2 can maintain excellent uneven wear resistance. The ratio (DC/DA) is more preferably not less than 0.40 from this viewpoint.

[0345] When the ratio (DC/DA) is set to be not greater than 0.80, the tubular portion 56 can effectively contribute to improvement in outer appearance quality and exhibition of traction performance. The ratio (DC/DA) is more preferably not greater than 0.75 from this viewpoint.

[0346] As described above, the tubular portion 56 is larger in groove width than the sipe body 54. Specifically, the maximum groove width WT of the tubular portion 56 is preferably not less than four times the groove width at the groove opening 52M of the sipe body 54, in other words, the groove width Wp of the transverse sipe 52, and is more preferably not less than five times. The tubular portion 56 can thus contribute to maintaining wet performance. The maximum groove width WT of the tubular portion 56 is preferably not greater than thirteen times the groove width Wp of the transverse sipe 52, and is more preferably not greater than twelve times. The tubular portion 56 is thus appropriately maintained in size. This suppresses a decrease in stiffness of the main block 50.

[0347] The tubular portion 56 includes a bottom surface including the groove bottom 52T of the transverse sipe 52. In the section shown in FIG. 6, the bottom surface of the tubular portion 56 has a contour indicated by an arc passing through the groove bottom 52T. FIG. 6 includes an arrow Rb indicating a radius of the arc.

[0348] The radius Rb of the arc indicating the contour of the bottom surface of the tubular portion 56 is preferably not less than 1.5 mm and not greater than 3.5 mm.

[0349] The radius Rb set to be not less than 1.5 mm effectively suppresses a crack in the groove bottom 52T. The radius Rb is more preferably not less than 2.0 mm from this viewpoint.

[0350] The radius Rb set to be not greater than 3.5 mm suppresses a decrease in stiffness of the main block 50 due to provision of the tubular portion 56 at the transverse sipe 52. This appropriately maintains stiffness of the main block 50. The tire 2 can be improved in uneven wear resistance. The radius Rb is more preferably not greater than 3.0 mm from this viewpoint.

[0351] As apparent from the above description, the present invention provides a heavy duty tire that can suppress a decrease in wet performance due to wear while reducing rolling resistance.

Examples

[0352] The following will describe the present invention in further detail by means of examples, etc., but the present invention is not limited to these examples.

[0353] Various chemicals used in Examples and Comparative Examples are described below.

[0354] NR: TSR20

[0355] SBR: HPR840 (S-SBR, styrene content: 10% by mass, vinyl content: 42% by mole, Tg: -60°C ., Mw: 190 thousand) manufactured by JSR Corporation

[0356] BR: UBEPOL BR (registered trademark) 150B (cis content: 97% by mole) manufactured by Ube Industries, Ltd.

[0357] Carbon black 1: DIABLACK N134 (N_2SA : 148 m^2/g) manufactured by Mitsubishi Chemical Corporation

[0358] Carbon black 2: SS550 (carbon black obtained from the pyrolysis process of tires) manufactured by Strebl Green Carbon Pte Ltd.

[0359] Silica 1: ULTRASIL 9100GR (N_2SA : 230 m^2/g , average primary particle diameter: 15 nm) manufactured by Evonik Degussa GmbH

[0360] Silica 2: K185 (amorphous silica refined from rice husks) manufactured by Wilmar

[0361] Silane coupling agent: Si266 (bis(3-triethoxysilylpropyl)disulfide) manufactured by Evonik Degussa GmbH

[0362] Resin component: Oppera PR-383 (hydrogenated DCPD/C9 resin, resin containing dicyclopentadiene, styrene, and indene as monomer components, softening point: 103° C.) manufactured by Exxon Mobil Corporation

[0363] Wax: OZOACE-0355 manufactured by NIPPON SEIRO CO., LTD.

[0364] Antioxidant 1: NOCRAC 6C (N-(1,3-dimethylbutyl)-N'-phenyl-p-phenylenediamine) manufactured by OUCHI SHINKO CHEMICAL INDUSTRIAL CO., LTD.

[0365] Antioxidant 2: NOCRAC RD (poly(2,2,4-trimethyl-1,2-dihydroquinoline)) manufactured by OUCHI SHINKO CHEMICAL INDUSTRIAL CO., LTD.

[0366] Stearic acid: bead stearic acid, Tsubaki, manufactured by NOF Corporation

[0367] Zinc oxide: Zinc Oxide Type-1 manufactured by Mitsui Mining & Smelting Co., Ltd.

[0368] Sulfur: HK-200-5 (powdery sulfur containing 5% of oil) manufactured by Hosoi Chemical Industry Co., Ltd.

[0369] Vulcanization accelerator: NOCCELER NS (N-t-butyl-2-benzothiazole sulfenamide) manufactured by OUCHI SHINKO CHEMICAL INDUSTRIAL CO., LTD.

Examples and Comparative Examples

[0370] In accordance with each blending formula shown in Tables 1 to 3, materials other than sulfur and a vulcanization accelerator are kneaded under a condition of 150° C. for 5 minutes by using a 1.7-L Banbury mixer manufactured by Kobe Steel, Ltd., to obtain a kneaded product. Next, the sulfur and the vulcanization accelerator are added to the obtained kneaded product, and the mixture is kneaded under a condition of 80° C. for 5 minutes by using an open roll, to obtain a rubber composition (uncrosslinked rubber composition). The obtained rubber composition is molded into a tread and attached together with other parts such as sidewalls to form an unvulcanized tire. The unvulcanized tire is press-vulcanized under a condition of 150° C. for 12 minutes to produce a test tire (size: 315/70R22.5, tire for trucks and buses). The tread pattern shown in FIG. 1 is used as the tread pattern of the test tire.

[Preparation Prior to Evaluation]

[0371] The tread of the test tire is subjected to buffing. Specifically, the tread is polished until the groove portion of the main lateral groove and the body portion of the circumferential narrow groove disappear while being careful not to expose the width reference position of the enlarged width portion in the circumferential narrow groove. The sipe portion of the main lateral groove and the inflection portion of the circumferential narrow groove are exposed on the tread surface. This reproduces the middle stage of wear.

[0372] Tables 1 to 3 show calculation results based on the following evaluation method of the test tire having wear at the middle stage reproduced by buffing.

[Rolling Resistance (RRC)]

[0373] Using a rolling resistance testing machine, a rolling resistance coefficient (RRC) is measured when each test tire in which the middle stage of wear is reproduced ran on a drum at a speed of 80 km/h under the following conditions. The reciprocals of the measured values of Example 1 and Comparative Examples 1 and 2 are represented as indexes with that of Comparative Example 2 as 100. The reciprocals of the measured values of Examples 2 and 3 and Comparative Examples 3 and 4 are represented as indexes with that of Comparative Example 4 as 100. The reciprocals of the measured values of Examples 4 and 5 and Comparative Examples 5 and 6 are represented as indexes with that of Comparative Example 6 as 100.

[0374] The results are shown in the cells for "RRC" in Tables 1 to 3 below. The higher the value is, the lower the rolling resistance of the tire is.

[0375] Rim: 9.00×22.5

[0376] Internal pressure: 900 kPa

[0377] Vertical load: 31.25 KN

[Wet Performance (WET)]

[0378] Wet performance (wet braking performance) is tested in accordance with R117-02 (ECE Regulation, No. 117, Revision 2) using a test vehicle described below. Test tires in which the middle stage of wear is reproduced are mounted to all wheels of the test vehicle. As to wet performance, a braking distance that the test vehicle traveled on a wet road surface from the start of braking at a predetermined initial speed until the test vehicle stopped is measured.

[0379] Test vehicle: truck with a load capacity of 10 t (2-D vehicle)

[0380] Load: 75% of the standard load weight

[0381] Wet road surface: water depth of 0.5 to 2 mm

[0382] Speed: 65 km/h

[0383] The measured values of Example 1 and Comparative Examples 1 and 2 are represented as indexes with that of Comparative Example 2 as 100 by the following equation.

(Wet performance index) =

(braking distance of tire of Comparative Example 2)/

(braking distance of each test tire)×100

[0384] The measured values of Examples 2 and 3 and Comparative Examples 3 and 4 are represented as indexes with that of Comparative Example 4 as 100 by the following equation.

(Wet performance index) =

(braking distance of tire of Comparative Example 4)/

(braking distance of each test tire)×100

[0385] The measured values of Examples 4 and 5 and Comparative Examples 5 and 6 are represented as indexes with that of Comparative Example 6 as 100 by the following equation.

(Wet performance index) =

(braking distance of tire of Comparative Example 6)/

(braking distance of each test tire) × 100

[0386] The results are shown in the cells for “WET” in Tables 1 to 3 below. The higher the value is, the better the wet performance is.

1. A heavy duty tire comprising a tread formed from a rubber composition containing a rubber component including a styrene butadiene rubber and a filler including silica, the tread having a tread surface configured to come into contact with a road surface, wherein

the tread includes a plurality of circumferential grooves continuously extending circumferentially,

the plurality of circumferential grooves provides the tread with a plurality of land portions aligned axially, the plurality of land portions includes a plurality of main land portions positioned between the circumferential grooves adjacent to each other, each of the main land portions includes a plurality of main lateral grooves connecting the circumferential grooves adjacent to each other, the plurality of main lateral grooves provides the main land portions with a plurality of main blocks aligned circumferentially, each of the main lateral grooves includes a groove portion and a sipe portion positioned radially inside the groove portion and provided continuously to the groove portion, the sipe portion is smaller in groove width than the groove portion, the circumferential groove positioned between the main land portions adjacent to each other is a circumferential narrow groove, in the plurality of main land portions, the main land portions positioned axially outermost are outer main land portions, the circumferential groove positioned axially outside each of the outer main land portions is a circumferential wide groove larger in groove width than the circumferential narrow groove, the circumferential narrow groove includes a body portion and an enlarged width portion positioned radially inside the body portion, the body portion includes a body portion main body provided continuously from the enlarged width portion, the tread is deformed to bring facing wall surfaces of the circumferential narrow groove into contact with each other at the body portion main body, the enlarged width portion has a maximum groove width larger than a minimum groove width of the body portion main body, between the body portion main body and a position at which the enlarged width portion has the maximum groove width, a position at which the enlarged width portion has a groove width equal to 2.0 times the minimum groove width of the body portion main body is a width reference position, the groove portion has a groove depth MH smaller than a groove depth HB from a groove opening of the circumferential narrow groove to the width reference position, an amount CSB of the styrene butadiene rubber in 100 parts by mass of the rubber component is not less than 10 parts by mass, an amount BS of the silica per 100 parts by mass of the rubber component is not less than 15 parts by mass, and the amount CSB of the styrene butadiene rubber, the amount BS of the silica, the groove depth MH (mm) of the groove portion, and the groove depth HB (mm) from the groove opening of the circumferential narrow groove to the width reference position satisfy a relational expression: below,

$$(CSB + BS)/(HB - MH) \geq 5.$$

2. The heavy duty tire according to claim 1, wherein the rubber component further includes a natural rubber and a butadiene rubber, and the amount CSB of the styrene butadiene rubber, an amount CN of the natural rubber, and an amount CB of the butadiene rubber in 100 parts by mass of the rubber component satisfy a relational expression: below,

$$CN \geq CSB + CB.$$

3. The heavy duty tire according to claim 1, wherein an amount CS of the silica in 100 parts by mass of the filler is not less than 40 parts by mass in 100 parts by mass.
4. The heavy duty tire according to claim 1, wherein the silica includes silica made from a biomass material.
5. The heavy duty tire according to claim 1, wherein the filler includes silica having an average primary particle diameter of not greater than 16 nm.
6. The heavy duty tire according to claim 1, wherein the filler further includes carbon black, and the carbon black includes recycled carbon black.
7. The heavy duty tire according to claim 1, wherein the filler further includes carbon black, and the carbon black includes carbon black having an average primary particle diameter of not greater than 19 nm.
8. The heavy duty tire according to claim 1, wherein the rubber composition further contains a resin component.
9. The heavy duty tire according to claim 1, wherein a land ratio defined below is not less than 75%, land ratio: a ratio of a total area value of ground-contact surfaces of a plurality of land portions included in a ground-contact surface to an area value of an entirety of the ground-contact surface, the ground-contact surface being obtained by: applying a load, which is 100% of a normal load, to the tire, which is fitted on a normal rim and whose internal pressure is adjusted to a normal internal pressure, with a camber angle as 0 degrees; and bringing the tire into contact with a flat road surface.
10. The heavy duty tire according to claim 1, wherein each of the main blocks includes a transverse sipe traversing the main block, the transverse sipe includes a sipe body and a tubular portion positioned radially inside the sipe body, and the tubular portion is larger in groove width than the sipe body.
11. The heavy duty tire according to claim 10, wherein a groove bottom of the groove portion or the width reference position is positioned between a radially outer end and a radially inner end of the tubular portion.
12. The heavy duty tire according to claim 10, wherein the plurality of main land portions includes an inner main land portion positioned between the circumferential narrow grooves adjacent to each other, and the sipe body of the transverse sipe included in the main block of the inner main land portion extends in a zigzag manner in a longitudinal direction and a depth direction.
13. The heavy duty tire according to claim 1, wherein the circumferential narrow groove includes a first narrow groove close to a first end as one end of the tread

surface, a second narrow groove close to a second end as another end of the tread surface, and a connection narrow groove connecting the first narrow groove and the second narrow groove, and
the first narrow groove and the second narrow groove are alternately disposed circumferentially.

14. The heavy duty tire according to claim 1, wherein a styrene content of the styrene butadiene rubber is not less than 5% by mass and not greater than 24% by mass.

15. The heavy duty tire according to claim 1, wherein a vinyl content of the styrene butadiene rubber is not less than 26% by mole.
