INTER-INTEGRATED ACCESS AND BACKHAUL NODE CROSS-LINK INTERFERENCE MEASUREMENT AND REPORTING

RELATED APPLICATION

This application is a continuation of U.S. application Ser. No. 17/267,573, filed Feb. 10, 2021, now U.S. Pat. No. 11,979,764, which is a National Phase in the United States of PCT Application No. PCT/US2019/045667, filed on Aug. 8, 2019, which claims priority to U.S. Provisional Application No. 62/717,669 filed Aug. 10, 2018, each of which is hereby incorporated by reference in its entirety.

FIELD

Embodiments of the present disclosure generally relate to the field of wireless communication, and more particularly, to apparatuses, systems, and methods for inter-integrated access and backhaul node cross-link interference measurement reporting.

BACKGROUND

Integrated access and backhaul (IAB) networks may include IAB nodes that may communicatively couple with one by over-the-air (OTA) backhaul links and may communicatively couple with user equipments (UEs) by OTA access links. The access and backhaul links may share the same wireless channel.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments will be readily understood by the following detailed description in conjunction with the accompanying drawings. To facilitate this description, like reference numerals designate like structural elements. Embodiments are illustrated by way of example and not by way of limitation in the figures of the accompanying drawings.

FIG. 1 illustrates four scenarios within an IAB network in accordance with some embodiments.

FIG. 2 illustrates an example IAB architecture in accordance with some embodiments.

FIG. 3 illustrates an example operation flow/algorithmic structure in accordance with some embodiments.

FIG. 4 illustrates an infrastructure device in accordance with some embodiments.

FIG. 5 illustrates example components of a device in accordance with some embodiments.

FIG. 6 illustrates interfaces of baseband circuitry in accordance with some embodiments.

FIG. 7 illustrates components of an electronic device in accordance with some embodiments.

DETAILED DESCRIPTION

In the following detailed description, numerals within the accompanying drawings designate like parts throughout. While the detailed description and figures describe specific embodiments, other embodiments within the scope of the present disclosure may include structural or logical changes. Embodiments describe various operations as multiple discrete actions or operations in turn, in a manner that is most helpful in understanding the claimed subject matter. However, the order of description does not imply that these operations are necessarily order dependent. In particular,

2

these operations may be performed in orders different from the order of presentation. Further, various additional operations may be performed or described operations may be omitted in additional embodiments. The description may use the phrases “in an embodiment,” or “in embodiments,” which may each refer to one or more of the same or different embodiments. The terms “comprising,” “including,” “having,” and the like, as used with respect to embodiments of the present disclosure, are synonymous. For the purposes of the present disclosure, the phrases “A or B,” “A and/or B,” and “A/B” mean (A), (B), or (A and B).

In an IAB Network, both the backhaul and access link may suffer from inter-IAB-node cross-link interference (CLI). Embodiments herein provide measurement and reporting mechanisms at one or more IAB nodes to address inter-IAB-node CLI. In addition to describing the measurements and reporting with different level of details, embodiments introduce new RRC signaling/parameters.

FIG. 1 illustrates an IAB network 100 in four different communication states (or “cases”) in accordance with some embodiments. The IAB network 100 may include a IAB donor node (DN) 104, a victim IAB node 108, and interfering IAB node 112, and UEs 116 and 120. FIG. 1 only shows the reference numerals with respect to case 1; however, similar associations may also apply to cases 2-4. The solid line arrows may indicate transmission links among the different devices, while the dashed line arrows may indicate cross-link interference (CLI) link.

The DN 104 may be the radio access network (RAN) node that provides access to a core network. The DN 104 may communicate with the core network over a fiber backhaul link, or some other connection technology. The DN 104 may provide a wireless access link to one or more UEs and may further provide one or more wireless backhaul links to relay IAB nodes, for example, victim IAB node 108 and interfering IAB node 112. In some embodiments, the DN 104 may include a central unit (CU) to configure or schedule operations within the IAB network 100.

In the IAB network 100, the IAB nodes may transmit at the same time over various backhaul/access links. This may result in the wireless backhaul/access links experiencing inter-IAB-node CLI. The victim IAB node 108 may, for purposes of this discussion, be the IAB node that suffers from CLI sourced from the interfering IAB node 112. The “victim” and “interfering” adjectives are simply a matter of perspective for the present discussion and depend only on the point of analysis.

FIG. 1 part (a) shows case 1, in which victim IAB node 108 receives a downlink (DL) transmission in the backhaul link, interfering IAB node 112 transmits uplink (UL) transmission in the backhaul link.

FIG. 1 part (b) shows case 2 where the victim IAB node 108 receives a DL transmission in the backhaul link, interfering IAB node 112 transmits a DL transmission in the access link.

FIG. 1 part (c) shows case 3 where the victim IAB node 108 receives an UL transmission in the access link, interfering IAB node 112 transmits UL transmission in the backhaul link.

FIG. 1 part (d) shows case 4 where the victim IAB node 108 receives an UL transmission in the access link, interfering IAB node 112 transmits a DL transmission in the access link.

To address the CLI, one way is to let each IAB node take measurements of the interference level from its surrounding IAB nodes and report the measurements to the CU in the DN 104 for proper coordination among the IAB nodes to miti-

gate CLI. The present disclosure provides three inter-IAB nodes CLI measurement and reporting mechanisms at an IAB node, which will be described as the victim IAB node **108** in the present description.

Mechanism 1: RSRP Measurements Over Data Channels and Aggregate Reporting

In this mechanism, the IAB node who is receiving data (either from IAB DN DL transmission or its child node (for example, a UE) UL transmission) will conduct channel measurements and report to a DN. For example, the victim IAB node **108** may be receiving data in DL transmission from DN **104** or in UL transmission from UE **116**. The channel measurements may include Reference Signal Received Power (RSRP), Reference Signal Received Quality (RSRQ), or Signal to Interference plus Noise Ratio (SINR) measurements.

In embodiments, the IAB node can conduct the channel measurements based on reference signals (RSs) from its serving parent node and report results of the measurements to a CU in an IAB DN. The reference signals may be synchronization signals (SS), which may result in the corresponding measurements being SS-RSRP/SS-RSRQ/SS-SINR parameters. Additionally or alternatively the reference signals may be channel state information reference signals (CSI-RSs), which may result in the corresponding measurements being CSI-RSRP/CSI-RSRQ/CSI-SINR parameters.

In some embodiments, the victim IAB node **108** may transmit the measurement results (for example, RSRP/RSRP/SINR parameters) to the CU in the DN **104** through RRC signaling. This reporting mechanism will imply the overall CLI level without differentiating other IAB node's DL transmission or UL transmission that causes the CLI interference. It also may not differentiate the specific IAB node of the CLI interference.

For basic measurements and reporting mechanism, if the reporting values deteriorate, the CU may not differentiate whether it is because of channel condition or CLI interference. Hence, the corresponding next step actions of IAB CU may not be to the point to address the CLI issue

Mechanism 2: Measurements Based on DL/UL Reference Signals of Interfering IAB Nodes and Aggregated Reporting

In this mechanism, each IAB node may measure the interference level of reference signals from its surrounding IAB nodes with knowledge of the transmission directions of the surrounding IAB nodes. For example, the victim IAB node **108** may receive configuration information, from DN **104**, for example, that enables it to identify UL reference signals (e.g., from interfering IAB node **112** to DN **104** in the backhaul link) and DL reference signals (e.g., from interfering IAB node **112** to UE **120** in the access link). The victim IAB node **108** may aggregate measurements of the interference levels from all neighboring IAB nodes and report aggregated CLI levels to the DN **104**. A neighbor IAB node may be defined with respect to a particular IAB relay node as an IAB node that is in proximity with the IAB relay node. The proximity may be predetermined based on geographical distance or CLI potential.

In some embodiments, if the interfering IAB node **112** is transmitting data in DL in the access link, the victim IAB node **108** may base the measurement on CSI-RS or demodulation reference signal (DMRS) from the interfering IAB node **112**.

The victim IAB node **108** may receive, via RRC or other higher-layer signaling, configuration information that lists CSI-RS or DMRS configuration information for the best N neighboring cells (N may also be configured). These N

neighboring cells may be the IAB nodes that will most likely cause the cross-link interference.

In some embodiments, if the interfering IAB node **112** is transmitting data in UL in the backhaul link, the victim IAB node **108** may base the measurement on sounding reference signal (SRS) from that interfering IAB node **112**.

The victim IAB node **108** may receive, via RRC or other higher-layer signaling, configuration information that lists SRS configuration information for the best N neighboring cells. This may be similar to that described above with respect to CSI-RS/DMRS configuration information.

After the victim IAB node **108** performs the measurements on UL/DL reference signals transmitted by interfering IAB nodes (e.g., IAB node **112**), the victim IAB node **108** may port on an aggregated CLI interference level from all neighboring IAB nodes. The report may not specify CLI interference level from each interfering IAB node to save the reporting overhead. RRC signaling/parameters to support this report are provided below.

In some embodiments, the victim IAB node **108** may generate the report as an RRC message. MeasurementReport, with a measurement results (MeasResults) information element (IE) that includes the measured results. An example of the MeasResults IE is shown below.

```

MeasResults ::= SEQUENCE {
    measId
    measResultServingMOList,
    measResultNeighCells,
    measResultListNR,
    ... }
    OPTIONAL,
    measResultCLI-agg,
    MeasQuantityResults,
    OPTIONAL,
    ... }
MeasQuantityResults ::= SEQUENCE {
    rsrp,
    OPTIONAL,
    rsrq,
    OPTIONAL,
    sinr,
    OPTIONAL
}
  
```

The MeasResults IE may include a measurement identity (measID) to identify the report; and measurement results for serving cell (measResultServingMOList), neighboring cells (measResultNeighCells), and aggregated CLI (measResultCLI-agg). The aggregated CLI results may correspond to the aggregated CLI interference level from all neighboring IAB nodes and may re-use the MeasQuantityResults IE in 3GPP Technical Specification (TS) 38.331, v15.2.1 (2018 Jun. 21).

Mechanism 3: Measurements Based on Interfering IAB Nodes' Reference Signals and Reporting Each IAB Node Specifically

In this mechanism, the configuration and bases of the measurements may be the same as mechanism 2. For example, each IAB node may measure an interference level based on reference signals from its neighboring IAB nodes: CSI-RS or DMRS if the interfering IAB node DL transmission and SRS if the interfering IAB node UL transmission. After that, the measuring IAB nodes may report CLI interference level from each interfering IAB node specifically for the CU to coordinate.

Some embodiments may utilize RRC signaling for reporting of the inter-IAB node CLI measurement results. The RRC signaling may include a measurement results (MeasResults) IE as follows.

```

MeasResults ::=
  measId
  measResultServingMOList
  measResultNeighCells
  measResultListNR
  ... }
  OPTIONAL,
  measResultCLI-agg
  measResultCLI-list

```

SEQUENCE {
 MeasId,
 MeasResultServMOList,

The parameters of the measurement results IE that support embodiments are as follows.

In some embodiments, a measurement results CLI list (measResultCLI-list) field may include values corresponding to CLI interference levels from multiple interfering IAB nodes.

In some embodiments, a measurement results CLI list (measResultCLI-list) IE may include the highest interfering IAB nodes up to an integer number (M), which may be a parameter indicated by a maximum CLI report (maxCLI-Report) field.

In some embodiments, a measurement results CLI list (measResultCLI-list) IE may include CLI measurement reports from each interfering IAB node. This IE may include an IAB node identifier (IAB-NodeID) field that includes an

FIG. 2 shows an example IAB architecture 200 in accordance with various embodiments. In FIG. 2, UEs 204 (e.g., UEs 116 or 120 in FIG. 1 discussed infra) access various IAB relay nodes (RNs) 208. The IAB RNs 208 may be similar to, and substantially interchangeable with, victim IAB node 108 or interfering IAB node 112 of FIG. 1. As shown by FIG. 2, some IAB RNs 208 access other IAB RNs 208, and some IAB RNs 208 access a donor node (DN) 212, which may be similar to, and substantially interchangeable with, DN 104. The DN 212 (or IAB donor, IAB donor node, or anchor node) is a network node in an IAB deployment that terminates NG interfaces via wired connection(s). The DN 212 is a RAN node that provides a UE's interface to a 5th Generation Core Network (5GC) 216 and wireless backhauling functionality to IAB relay nodes.

In embodiments, the IAB system architecture 200 supports multi-hop backhauling. IAB multi-hop backhauling provides more range extension than single hopping systems. Multi-hop backhauling further enables backhauling around obstacles (e.g., buildings in urban environment for in-clutter deployments). The maximum number of hops in a deployment depends on many factors such as frequency, cell density, propagation environment, traffic load, various KPIs, KQIs, and/or other like factors. From the architecture perspective, flexibility in hop count is desirable, and therefore, the IAB system may not impose limits on the number of backhaul hops.

The IAB system architecture 200 also supports topology adaptation. Topology adaptation refers to procedures that autonomously reconfigure the backhaul network under circumstances, such as blockage or local congestion without discontinuing services for UEs and/or to mitigate service

disruption for UEs. For example, wireless backhaul links may be vulnerable to blockage due to moving objects such as vehicles, weather-related events (e.g., seasonal changes (foliage)), infrastructure changes (e.g., new buildings), and/or the like. These vulnerabilities may apply to physically stationary IAB-nodes and/or mobile IAB-nodes. Also, traffic variations can create uneven load distribution on wireless backhaul links leading to local link or node congestion.

In embodiments where multi-hop and topology adaptation are supported, the IAB relay nodes include topology management mechanisms and route selection and optimization (RSO) mechanisms. Topology management mechanisms include protocol stacks, interfaces between IAB nodes, control and user plane procedures for identifying one or more hops in the IAB network, forwarding traffic via one or multiple wireless backhaul links in the IAB network, handling of QoS, and the like. The RSO mechanisms include mechanisms for discovery and management of backhaul links; RAN-based mechanisms to support dynamic route selection (potentially without core network involvement) to accommodate short-term blocking and transmission of latency-sensitive traffic across backhaul links; and mechanisms for evaluating different resource allocations/routes across multiple nodes for end-to-end RSO.

Any of the IAB relay nodes **208** and DN **212** may be configured to operate in accordance with various embodiments of this disclosure. For example, the DN **212** may provide any of the IAB relay nodes **208** with RS configuration information that the IAB relay nodes **208** may use to perform measurements and reporting is described herein.

FIG. 3 illustrates an operation flow/algorithmic structure **300** in accordance with some embodiments. An IAB node may perform the operation flow/algorithmic structure **300**. For example, in some embodiments, the victim IAB node **108** or any of the relay nodes **208** (or components thereof) may perform the operation flow/algorithmic structure **300**.

The operation flow/algorithmic structure **300** may include, at **304**, receiving reference signal configuration information from an IAB donor. The configuration information may be received through RRC signaling or another higher-layer signaling. The signaling may occur upon an initial connection or a reconfiguration of an existing connection.

The reference signal configuration information may provide information related to synchronization signals, CSI-RS signals, or DMRS signals. These reference signals may be transmitted from IAB donor/relay nodes.

In some embodiments, the configuration information may be specific to a particular IAB node and include information about reference signals transmitted by neighboring IAB nodes. In other embodiments, the configuration information may be more generic.

The operation flow/algorithmic structure **300** may further include, at **308**, performing measurements based on the reference signals. In some embodiments, the measurements may include RSRP, RSRQ, or SINR measurements based on the underlying reference signals.

The operation flow/algorithmic structure **300** may further include, at **312**, transmitting a measurement report to a donor node. In some embodiments, the measurement report may be transmitted to a central unit within a donor node (or disposed elsewhere).

In various embodiments, the measurement report may include general reference signal measurements, aggregated cross-link interference levels, or cross-link interference level specific to particular IABs. In addition to including the measurement results, the measurement report may include

additional information such as, but not limited to, transmission direction, IAB node identifiers, etc. in various embodiments, the measurement report may include any of the information elements, parameters, or fields described above with respect to the RRC measurement results information elements.

FIG. 4 illustrates an example of infrastructure equipment **400** in accordance with various embodiments. The infrastructure equipment **400** (or “system **400**”) may be implemented as a donor node (for example, DN **104** or DN **212**) or an IAB relay node (for example, victim IAB node **108** or IAB relay node **208**) shown and described previously. The system **400** may include one or more of application circuitry **405**, baseband circuitry **410**, one or more radio front end modules **415**, memory circuitry **420**, power management integrated circuitry (PMIC) **425**, power tee circuitry **430**, network controller circuitry **435**, network interface connector **440**, satellite positioning circuitry **445**, and user interface **450**. In some embodiments, the device **400** may include additional elements such as, for example, memory/storage, display, camera, sensor, or input/output (I/O) interface. In other embodiments, the components described below may be included in more than one device (e.g., said circuitries may be separately included in more than one device for CRAN, vBBU, or other like implementations).

The term “circuitry” may refer to, be a part of, or include hardware components such as an electronic circuit, a logic circuit, a processor (shared, dedicated, or group) and/or memory (shared, dedicated, or group), an Application Specific Integrated Circuit (ASIC), a field-programmable device (FPD) (e.g., a field-programmable gate array (FPGA), a programmable logic device (PLD), a complex PLD (CPLD), a high-capacity PLD (HCPLD), a structured ASIC, or a programmable System on Chip (SoC)), digital signal processors (DSPs), etc., that are configured to provide the described functionality. In some embodiments, the circuitry may execute one or more software or firmware programs to provide at least some of the described functionality. In addition, the term “circuitry” may also refer to a combination of one or more hardware elements (or a combination of circuits used in an electrical or electronic system) with the program code used to carry out the functionality of that program code. In these embodiments, the combination of hardware elements and program code may be referred to as a particular type of circuitry.

The terms “application circuitry” and/or “baseband circuitry” may be considered synonymous to, and may be referred to as, “processor circuitry.” As used herein, the term “processor circuitry” may refer to, is part of, or includes circuitry capable of sequentially and automatically carrying out a sequence of arithmetic or logical operations, or recording, storing, and/or transferring digital data. The term “processor circuitry” may refer to one or more application processors, one or more baseband processors, a physical central processing unit (CPU), a single-core processor, a dual-core processor, a triple-core processor, a quad-core processor, and/or any other device capable of executing or otherwise operating computer-executable instructions, such as program code, software modules, and/or functional processes.

Application circuitry **405** may include one or more central processing unit (CPU) cores and one or more of cache memory, low drop-out voltage regulators (LDOs), interrupt controllers, serial interfaces such as SPI, I2C or universal programmable serial interface module, real time clock (RTC), timer-counters including interval and watchdog timers, general purpose input/output (I/O or IO), memory card

controllers such as Secure Digital (SD) MultiMediaCard (MMC) or similar, Universal Serial Bus (USB) interfaces, Mobile Industry Processor Interface (MIPI) interfaces and Joint Test Access Group (JTAG) test access ports. As examples, the application circuitry **405** may include one or more Intel Pentium®, Core®, or Xeon® processor(s); Advanced Micro Devices (AMD) Ryzen® processor(s), Accelerated Processing Units (APUs), or Epyc® processors; and/or the like. In some embodiments, the system **400** may not utilize application circuitry **405**, and instead may include a special-purpose processor/controller to process IP data received from an EPC or 5GC, for example.

Additionally or alternatively, application circuitry **405** may include circuitry such as, but not limited to, one or more a field-programmable devices (FPDs) such as field-programmable gate arrays (FPGAs) and the like; programmable logic devices (PLDs) such as complex PLDs (CPLDs), high-capacity PLDs (HCPLDs), and the like; ASICs such as structured ASICs and the like; programmable SoCs (PSoCs); and the like. In such embodiments, the circuitry of application circuitry **405** may comprise logic blocks or logic fabric, and other interconnected resources that may be programmed to perform various functions, such as the procedures, methods, functions, etc. of the various embodiments discussed herein. In such embodiments, the circuitry of application circuitry **405** may include memory cells (e.g., erasable programmable read-only memory (EPROM), electrically erasable programmable read-only memory (EEPROM), flash memory, static memory (e.g., static random access memory (SRAM), anti-fuses, etc.)) used to store logic blocks, logic fabric, data, etc. in look-up-tables (LUTs) and the like.

The baseband circuitry **410** may be implemented, for example, as a solder-down substrate including one or more integrated circuits, a single packaged integrated circuit soldered to a main circuit board or a multi-chip module containing two or more integrated circuits.

Although not shown, baseband circuitry **410** may comprise one or more digital baseband systems, which may be coupled via an interconnect subsystem to a CPU subsystem, an audio subsystem, and an interface subsystem. The digital baseband subsystems may also be coupled to a digital baseband interface and a mixed-signal baseband subsystem via another interconnect subsystem. Each of the interconnect subsystems may include a bus system, point-to-point connections, network-on-chip (NOC) structures, and/or some other suitable bus or interconnect technology, such as those discussed herein. The audio subsystem may include digital signal processing circuitry, buffer memory, program memory, speech processing accelerator circuitry, data converter circuitry such as analog-to-digital and digital-to-analog converter circuitry, analog circuitry including one or more of amplifiers and filters, and/or other like components. In an aspect of the present disclosure, baseband circuitry **410** may include protocol processing circuitry with one or more instances of control circuitry (not shown) to provide control functions for the digital baseband circuitry and/or radio frequency circuitry (e.g., the radio front end modules **415**).

User interface circuitry **450** may include one or more user interfaces designed to enable user interaction with the system **400** or peripheral component interfaces designed to enable peripheral component interaction with the system **400**. User interfaces may include, but are not limited to, one or more physical or virtual buttons (e.g., a reset button), one or more indicators (e.g., light emitting diodes (LEDs)), a physical keyboard or keypad, a mouse, a touchpad, a touchscreen, speakers or other audio emitting devices, micro-

phones, a printer, a scanner, a headset, a display screen or display device, etc. Peripheral component interfaces may include, but are not limited to, a nonvolatile memory port, a universal serial bus (USB) port, an audio jack, a power supply interface, etc.

The radio front end modules (RFEMs) **415** may comprise a millimeter wave RFEM and one or more sub-millimeter wave radio frequency integrated circuits (RFICs). In some implementations, the one or more sub-millimeter wave RFICs may be physically separated from the millimeter wave RFEM. The RFICs may include connections to one or more antennas or antenna arrays, and the RFEM may be connected to multiple antennas. In alternative implementations, both millimeter wave and sub-millimeter wave radio functions may be implemented in the same physical radio front end module **415**. The RFEMs **415** may incorporate both millimeter wave antennas and sub-millimeter wave antennas.

The memory circuitry **420** may include one or more of volatile memory including dynamic random access memory (DRAM) and/or synchronous dynamic random access memory (SD RAM), and nonvolatile memory (NVM) including high-speed electrically erasable memory (commonly referred to as Flash memory), phase change random access memory (PRAM), magnetoresistive random access memory (MRAM), etc., and may incorporate the three-dimensional (3D) cross-point (XPOINT) memories from Intel® and Micron®.

Memory circuitry **420** may be implemented as one or more of solder down packaged integrated circuits, socketed memory modules and plug-in memory cards.

The PMIC **425** may include voltage regulators, surge protectors, power alarm detection circuitry, and one or more backup power sources such as a battery or capacitor. The power alarm detection circuitry may detect one or more of brown out (under-voltage) and surge (over-voltage) conditions. The power tee circuitry **430** may provide for electrical power drawn from a network cable to provide both power supply and data connectivity to the infrastructure equipment **400** using a single cable.

The network controller circuitry **435** may provide connectivity to a network using a standard network interface protocol such as Ethernet, Ethernet over GRE Tunnels, Ethernet over Multiprotocol Label Switching (MPLS), or some other suitable protocol. Network connectivity may be provided to/from the infrastructure equipment **400** via network interface connector **440** using a physical connection, which may be electrical (commonly referred to as a “copper interconnect”), optical, or wireless. The network controller circuitry **435** may include one or more dedicated processors and/or FPGAs to communicate using one or more of the aforementioned protocols. In some implementations, the network controller circuitry **435** may include multiple controllers to provide connectivity to other networks using the same or different protocols.

The positioning circuitry **445** may include circuitry to receive and decode signals transmitted by one or more navigation satellite constellations of a global navigation satellite system (GNSS). Examples of navigation satellite constellations (or GNSS) may include United States’ Global Positioning System (GPS), Russia’s Global Navigation System (GLONASS), the European Union’s Galileo system, China’s BeiDou Navigation Satellite System, a regional navigation system or GNSS augmentation system (e.g., Navigation with Indian Constellation (NAVIC), Japan’s Quasi-Zenith Satellite System (QZSS), France’s Doppler Orbitography and Radio-positioning Integrated by Satellite

11

(DORIS), etc.), or the like. The positioning circuitry **445** may comprise various hardware elements (e.g., including hardware devices such as switches, filters, amplifiers, antenna elements, and the like to facilitate OTA communications) to communicate with components of a positioning network, such as navigation satellite constellation nodes.

Nodes or satellites of the navigation satellite constellation(s) (“GNSS nodes”) may provide positioning services by continuously transmitting or broadcasting GNSS signals along a line of sight, which may be used by GNSS receivers (e.g., positioning circuitry **445** and/or positioning circuitry implemented by UEs XQ01, XQ02, or the like) to determine their GNSS position. The GNSS signals may include a pseudorandom code (e.g., a sequence of ones and zeros) that is known to the GNSS receiver and a message that includes a time of transmission (ToT) of a code epoch (e.g., a defined point in the pseudorandom code sequence) and the GNSS node position at the ToT. The GNSS receivers may monitor/measure the GNSS signals transmitted/broadcasted by a plurality of GNSS nodes (e.g., four or more satellites) and solve various equations to determine a corresponding GNSS position (e.g., a spatial coordinate). The GNSS receivers also implement clocks that are typically less stable and less precise than the atomic clocks of the GNSS nodes, and the GNSS receivers may use the measured GNSS signals to determine the GNSS receivers’ deviation from true time (e.g., an offset of the GNSS receiver clock relative to the GNSS node time). In some embodiments, the positioning circuitry **445** may include a Micro-Technology for Positioning, Navigation, and Timing (Micro-PNT) integrated circuit (IC) that uses a master timing clock to perform position tracking/estimation without GNSS assistance.

The GNSS receivers may measure the time of arrivals (ToAs) of the GNSS signals from the plurality of GNSS nodes according to its own clock. The GNSS receivers may determine time of flight (ToF) values for each received GNSS signal from the ToAs and the ToTs, and then may determine, from the ToFs, a three-dimensional (3D) position and clock deviation. The 3D position may then be converted into a latitude, longitude and altitude. The positioning circuitry **445** may provide data to application circuitry **405** that may include one or more of position data or time data. Application circuitry **405** may use the time data to synchronize operations with other radio base stations (e.g., RAN nodes XQ11 or the like).

The components shown by FIG. 4 may communicate with one another using interface circuitry. As used herein, the term “interface circuitry” may refer to, is part of, or includes circuitry providing for the exchange of information between two or more components or devices. The term “interface circuitry” may refer to one or more hardware interfaces, for example, buses, input/output (I/O) interfaces, peripheral component interfaces, network interface cards, and/or the like. Any suitable bus technology may be used in various implementations, which may include any number of technologies, including industry standard architecture (ISA), extended ISA (EISA), peripheral component interconnect (PCI), peripheral component interconnect extended (PCIx), PCI express (PCIe), or any number of other technologies. The bus may be a proprietary bus, for example, used in a SoC based system. Other bus systems may be included, such as an I2C interface, an SPI interface, point to point interfaces, and a power bus, among others.

FIG. 5 illustrates example components of baseband circuitry **410** and radio front end modules (RFEM) **415** in accordance with various embodiments. As shown, the RFEMs **415** may include Radio Frequency (RF) circuitry

12

506, front-end module (FEM) circuitry **508**, one or more antennas **511** coupled together at least as shown.

The baseband circuitry **410** may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The baseband circuitry **410** may include one or more baseband processors or control logic to process baseband signals received from a receive signal path of the RF circuitry **506** and to generate baseband signals for a transmit signal path of the RF circuitry **506**. Baseband processing circuitry **410** may interface with the application circuitry **405** for generation and processing of the baseband signals and for controlling operations of the RF circuitry **506**. For example, in some embodiments, the baseband circuitry **410** may include a third generation (3G) baseband processor **504A**, a 4G baseband processor **504B**, a 5G baseband processor **504C**, or other baseband processor(s) **504D** for other existing generations, generations in development or to be developed in the future (e.g., second generation (2G), sixth generation (6G), etc.). The baseband circuitry **410** (e.g., one or more of baseband processors **504A-D**) may handle various radio control functions that enable communication with one or more radio networks via the RF circuitry **506**. In other embodiments, some or all of the functionality of baseband processors **504A-D** may be included in modules stored in the memory **504G** and executed via a Central Processing Unit (CPU) **504E**. The radio control functions may include, but are not limited to, signal modulation/demodulation, encoding/decoding, radio frequency shifting, etc. In some embodiments, modulation/demodulation circuitry of the baseband circuitry **410** may include Fast-Fourier Transform (FFT), precoding, or constellation mapping/demapping functionality. In some embodiments, encoding/decoding circuitry of the baseband circuitry **410** may include convolution, tail-biting convolution, turbo, Viterbi, or Low Density Parity Check (LDPC) encoder/decoder functionality.

Embodiments of modulation/demodulation and encoder/decoder functionality are not limited to these examples and may include other suitable functionality in other embodiments.

In some embodiments, the baseband circuitry **410** may include one or more audio digital signal processor(s) (DSP) **504F**. The audio DSP(s) **504F** may include elements for compression/decompression and echo cancellation and may include other suitable processing elements in other embodiments. Components of the baseband circuitry may be suitably combined in a single chip or a single chipset, or disposed on a same circuit board in some embodiments. In some embodiments, some or all of the constituent components of the baseband circuitry **410** and the application circuitry **405** may be implemented together such as, for example, on a system on a chip (SOC).

In some embodiments, the baseband circuitry **410** may provide for communication compatible with one or more radio technologies. For example, in some embodiments, the baseband circuitry **410** may support communication with an E-UTRAN or other WMAN, a WLAN, a WPAN. Embodiments in which the baseband circuitry **410** is configured to support radio communications of more than one wireless protocol may be referred to as multi-mode baseband circuitry.

RF circuitry **506** may enable communication with wireless networks using modulated electromagnetic radiation through a non-solid medium. In various embodiments, the RF circuitry **506** may include switches, filters, amplifiers, etc. to facilitate the communication with the wireless network. RF circuitry **506** may include a receive signal path,

which may include circuitry to down-convert RF signals received from the FEM circuitry 508 and provide baseband signals to the baseband circuitry 410. RF circuitry 506 may also include a transmit signal path, which may include circuitry to up-convert baseband signals provided by the baseband circuitry 410 and provide RF output signals to the FEM circuitry 508 for transmission.

In some embodiments, the receive signal path of the RF circuitry 506 may include mixer circuitry 506a, amplifier circuitry 506b and filter circuitry 506c. In some embodiments, the transmit signal path of the RF circuitry 506 may include filter circuitry 506c and mixer circuitry 506a. RF circuitry 506 may also include synthesizer circuitry 506d for synthesizing a frequency for use by the mixer circuitry 506a of the receive signal path and the transmit signal path. In some embodiments, the mixer circuitry 506a of the receive signal path may be configured to down-convert RF signals received from the FEM circuitry 508 based on the synthesized frequency provided by synthesizer circuitry 506d.

The amplifier circuitry 506b may be configured to amplify the down-converted signals and the filter circuitry 506c may be a low-pass filter (LPF) or band-pass filter (BPF) configured to remove unwanted signals from the down-converted signals to generate output baseband signals. Output baseband signals may be provided to the baseband circuitry 410 for further processing. In some embodiments, the output baseband signals may be zero-frequency baseband signals, although this is not a requirement. In some embodiments, mixer circuitry 506a of the receive signal path may comprise passive mixers, although the scope of the embodiments is not limited in this respect.

In some embodiments, the mixer circuitry 506a of the transmit signal path may be configured to up-convert input baseband signals based on the synthesized frequency provided by the synthesizer circuitry 506d to generate RF output signals for the FEM circuitry 508. The baseband signals may be provided by the baseband circuitry 410 and may be filtered by filter circuitry 506c.

In some embodiments, the mixer circuitry 506a of the receive signal path and the mixer circuitry 506a of the transmit signal path may include two or more mixers and may be arranged for quadrature downconversion and upconversion, respectively. In some embodiments, the mixer circuitry 506a of the receive signal path and the mixer circuitry 506a of the transmit signal path may include two or more mixers and may be arranged for image rejection (e.g., Hartley image rejection). In some embodiments, the mixer circuitry 506a of the receive signal path and the mixer circuitry 506a of the transmit signal path may be arranged for direct downconversion and direct upconversion, respectively. In some embodiments, the mixer circuitry 506a of the receive signal path and the mixer circuitry 506a of the transmit signal path may be configured for super-heterodyne operation.

In some embodiments, the output baseband signals and the input baseband signals may be analog baseband signals, although the scope of the embodiments is not limited in this respect. In some alternate embodiments, the output baseband signals and the input baseband signals may be digital baseband signals. In these alternate embodiments, the RF circuitry 506 may include analog-to-digital converter (ADC) and digital-to-analog converter (DAC) circuitry and the baseband circuitry 410 may include a digital baseband interface to communicate with the RF circuitry 506.

In some dual-mode embodiments, a separate radio IC circuitry may be provided for processing signals for each spectrum, although the scope of the embodiments is not limited in this respect.

In some embodiments, the synthesizer circuitry 506d may be a fractional-N synthesizer or a fractional NIN+1 synthesizer, although the scope of the embodiments is not limited in this respect as other types of frequency synthesizers may be suitable. For example, synthesizer circuitry 506d may be a delta-sigma synthesizer, a frequency multiplier, or a synthesizer comprising a phase-locked loop with a frequency divider.

The synthesizer circuitry 506d may be configured to synthesize an output frequency for use by the mixer circuitry 506a of the RF circuitry 506 based on a frequency input and a divider control input. In some embodiments, the synthesizer circuitry 506d may be a fractional NIN+1 synthesizer.

In some embodiments, frequency input may be provided by a voltage controlled oscillator (VCO), although that is not a requirement. Divider control input may be provided by either the baseband circuitry 410 or the application circuitry 405 depending on the desired output frequency. In some embodiments, a divider control input (e.g., N) may be determined from a look-up table based on a channel indicated by the application circuitry 405.

Synthesizer circuitry 506d of the RF circuitry 506 may include a divider, a delay-locked loop (DLL), a multiplexer and a phase accumulator. In some embodiments, the divider may be a dual modulus divider (DMD) and the phase accumulator may be a digital phase accumulator (DPA). In some embodiments, the DMD may be configured to divide the input signal by either N or $N+1$ (e.g., based on a carry out) to provide a fractional division ratio. In some example embodiments, the DLL may include a set of cascaded, tunable, delay elements, a phase detector, a charge pump and a D-type flip-flop. In these embodiments, the delay elements may be configured to break a VCO period up into N_d equal packets of phase, where N_d is the number of delay elements in the delay line. In this way, the DLL provides negative feedback to help ensure that the total delay through the delay line is one VCO cycle.

In some embodiments, synthesizer circuitry 506d may be configured to generate a carrier frequency as the output frequency, while in other embodiments, the output frequency may be a multiple of the carrier frequency (e.g., twice the carrier frequency, four times the carrier frequency) and used in conjunction with quadrature generator and divider circuitry to generate multiple signals at the carrier frequency with multiple different phases with respect to each other. In some embodiments, the output frequency may be a LO frequency (fLO). In some embodiments, the RF circuitry 506 may include an IQ/polar converter.

FEM circuitry 508 may include a receive signal path, which may include circuitry configured to operate on RF signals received from one or more antennas 511, amplify the received signals and provide the amplified versions of the received signals to the RF circuitry 506 for further processing. FEM circuitry 508 may also include a transmit signal path, which may include circuitry configured to amplify signals for transmission provided by the RF circuitry 506 for transmission by one or more of the one or more antennas 511.

In various embodiments, the amplification through the transmit or receive signal paths may be done solely in the RF circuitry 506, solely in the FEM circuitry 508, or in both the RF circuitry 506 and the FEM circuitry 508.

15

In some embodiments, the FEM circuitry **508** may include a TX/RX switch to switch between transmit mode and receive mode operation. The FEM circuitry **508** may include a receive signal path and a transmit signal path. The receive signal path of the FEM circuitry **508** may include an LNA to amplify received RF signals and provide the amplified received RF signals as an output (e.g., to the RF circuitry **506**). The transmit signal path of the FEM circuitry **508** may include a power amplifier (PA) to amplify input RF signals (e.g., provided by RF circuitry **506**), and one or more filters to generate RF signals for subsequent transmission (e.g., by one or more of the one or more antennas **511**).

Processors of the application circuitry **405** and processors of the baseband circuitry **410** may be used to execute elements of one or more instances of a protocol stack. For example, processors of the baseband circuitry **410**, alone or in combination, may be used execute Layer 3, Layer 2, or Layer 1 functionality, while processors of the application circuitry **405** may utilize data (e.g., packet data) received from these layers and further execute Layer 4 functionality (e.g., TCP and UDP layers). As referred to herein, Layer 3 may comprise a RRC layer, described in further detail below. As referred to herein, Layer 2 may comprise a MAC layer, an RLC layer, and a PDCP layer, described in further detail below. As referred to herein, Layer 1 may comprise a PHY layer of a UE/RAN node, described in further detail below.

FIG. 6 illustrates example interfaces of baseband circuitry in accordance with various embodiments. As discussed above, the baseband circuitry **410** of FIGS. 4 and 5 may comprise processors **504A-504E** and a memory **504G** utilized by said processors. Each of the processors **504A-504E** may include a memory interface, **604A-604E**, respectively, to send/receive data to/from the memory **504G**.

The baseband circuitry **410** may further include one or more interfaces to communicatively couple to other circuitries/devices, such as a memory interface **612** (e.g., an interface to send/receive data to/from memory external to the baseband circuitry **410**), an application circuitry interface **614** (e.g., an interface to send/receive data to/from the application circuitry **405** of FIG. 4), an RF circuitry interface **616** (e.g., an interface to send/receive data to/from RF circuitry **506**), a wireless hardware connectivity interface **618** (e.g., an interface to send/receive data to/from Near Field Communication (NFC) components, Bluetooth® components (e.g., Bluetooth® Low Energy), Wi-Fi® components, and other communication components), and a power management interface **620** (e.g., an interface to send/receive power or control signals to/from the PMIC **425**).

FIG. 7 is a block diagram illustrating components, according to some example embodiments, able to read instructions from a machine-readable or computer-readable medium (e.g., anon-transitory machine-readable storage medium) and perform any one or more of the methodologies discussed herein. Specifically, FIG. 7 shows a diagrammatic representation of hardware resources **700** including one or more processors (or processor cores) **710**, one or more memory/storage devices **720**, and one or more communication resources **730**, each of which may be communicatively coupled via a bus **740**. As used herein, the term “computing resource,” “hardware resource,” etc., may refer to a physical or virtual device, a physical or virtual component within a computing environment, and/or a physical or virtual component within a particular device, such as computer devices, mechanical devices, memory space, processor/CPU time and/or processor/CPU usage, processor and accelerator loads, hardware time or usage, electrical power, input/output

16

operations, ports or network sockets, channel/link allocation, throughput, memory usage, storage, network, database and applications, and/or the like. For embodiments where node virtualization (e.g., NFV) is utilized, a hypervisor **702** may be executed to provide an execution environment for one or more network slices/sub-slices to utilize the hardware resources **700**. A “virtualized resource” may refer to compute, storage, and/or network resources provided by virtualization infrastructure to an application, device, system, etc.

The processors **710** (e.g., a central processing unit (CPU), a reduced instruction set computing (RISC) processor, a complex instruction set computing (CISC) processor, a graphics processing unit (GPU), a digital signal processor (DSP) such as a baseband processor, an application specific integrated circuit (ASIC), a radio-frequency integrated circuit (RFIC), another processor, or any suitable combination thereof) may include, for example, a processor **712** and a processor **714**.

The memory/storage devices **720** may include main memory, disk storage, or any suitable combination thereof. The memory/storage devices **720** may include, but are not limited to, any type of volatile or nonvolatile memory such as dynamic random access memory (DRAM), static random access memory (SRAM), erasable programmable read-only memory (EPROM), electrically erasable programmable read-only memory (EEPROM), Flash memory, solid-state storage, etc.

The communication resources **730** may include interconnection or network interface components or other suitable devices to communicate with one or more peripheral devices **704** or one or more databases **706** via a network **708**. For example, the communication resources **730** may include wired communication components (e.g., for coupling via a universal serial bus (USB)), cellular communication components, NFC components, Bluetooth® components (e.g., Bluetooth® Low Energy), Wi-Fi® components, and other communication components. As used herein, the term “network resource” or “communication resource” may refer to computing resources that are accessible by computer devices via a communications network. The term “system resources” may refer to any kind of shared entities to provide services, and may include computing and/or network resources. System resources may be considered as a set of coherent functions, network data objects or services, accessible through a server where such system resources reside on a single host or multiple hosts and are clearly identifiable.

Instructions **750** may comprise software, a program, an application, an applet, an app, or other executable code for causing at least any of the processors **710** to perform any one or more of the methodologies discussed herein. The instructions **750** may reside, completely or partially, within at least one of the processors **710** (e.g., within the processor’s cache memory), the memory/storage devices **720**, or any suitable combination thereof.

Furthermore, any portion of the instructions **750** may be transferred to the hardware resources **700** from any combination of the peripheral devices **704** or the databases **706**. Accordingly, the memory of processors **710**, the memory/storage devices **720**, the peripheral devices **704**, and the databases **706** are examples of computer-readable and machine-readable media.

For one or more embodiments, at least one of the components set forth in one or more of the preceding figures may be configured to perform one or more operations, techniques, processes, and/or methods as set forth in the example section below. For example, the baseband circuitry as described above in connection with one or more of the

preceding figures may be configured to operate in accordance with one or more of the examples set forth below. For another example, circuitry associated with a UE, base station, network element, etc. as described above in connection with one or more of the preceding figures may be configured to operate in accordance with one or more of the examples set forth below in the example section.

Some non-limiting examples are provided below.

Example 1 includes a method comprising receiving radio resource control (RRC) signaling from a IAB donor node, the RRC signaling to include configuration information with respect to reference signals (e.g., SS, CSI-RS, or DMRS) of the IAB donor node or one or more neighboring IAB nodes; and performing one or more measurements based on the reference signals of the donor node or the one or more neighboring IAB nodes; and transmitting measurement report to the IAB donor node, the measurement report to include an indication of results of the one or more measurements.

Example 2 may include the method of example 1 or some other example herein wherein the one or more measurements includes RSRP measurement, an RSRQ measurement, or an SINR measurement.

Example 3 may include the method of example 1 or some other example herein, wherein the configuration information is with respect to reference signals of a plurality of neighboring IAB nodes and the method further comprises: generating an aggregated cross-link interference level based on the one or more measurements based on the reference signals of the plurality of neighboring IAB nodes, wherein the measurement report is to include an indication of the aggregated cross-link interference level.

Example 4 may include the method of example 3 or some other example herein, wherein the measurement report is an RRC message that includes a measurement results information element with the indication of the aggregated cross-link interference level.

Example 5 may include the method of example 1 or some other example herein, wherein the configuration information is with respect to reference signals of a plurality of neighboring IAB nodes and the method further comprises: generating a plurality of cross-link interference levels respectively associated with the plurality of neighboring IAB nodes, where the measurement report is to include an indication of at least one of the plurality of cross-link interference levels.

Example 6 may include the method of example 5 or some other example herein, wherein the measurement report is an RRC message that includes a measurement results information element that includes: a measurement results CLI list that includes the indication of the at least one cross-link interference level.

Example 7 may include the method of example 6 or some other example herein, further comprising: identifying an integer (M) based on a maximum CLI report parameter provided by the IAB donor node, wherein the at least one cross-link interference level includes no more than M cross-link interference levels.

Example 8 may include the method of example 7 or some other example herein, further comprising: selecting, from the plurality of cross-link interference levels, the M highest cross-link interference levels as the at least one cross-link interference level to be included in the measurement report.

Example 9 may include the method of example 6 or some other example herein, wherein the measurement results CLI

list includes an indication of an interfering IAB node identifier corresponding to each of the at least one cross-link interference levels.

Example 10 may include the method of example 6 or some other example herein, wherein the measurement results CLI list includes an indication of an uplink or downlink transmission direction corresponding to each of the at least one cross-link interference levels.

Example 11 may include a method comprising storing configuration information, the configuration information to provide information related to reference signals (for example, SS, CSI-RS, or DMRS) of the IAB donor node or one or more IAB nodes that are in proximity with an IAB relay node; generating a radio resource control (RRC) message to include the configuration information; and transmitting the RRC message to the IAB relay node.

Example 12 may include the method of example 11 or some other example herein, wherein the configuration information is to configure the IAB relay node to perform one or more measurements that include a reference signal received power measurement, a reference signal received quality measurements, or a signal-to-interference-plus-noise ratio measurement with respect to the reference signals.

Example 13 may include the method of example 11 or some other example herein, further comprising identifying the one or more IAB nodes that are in proximity with the IAB relay node, and generate the configuration information to include information related to reference signals of the one or more IAB nodes.

Example 14 may include the method of example 11 or some other example herein, wherein the configuration information includes a maximum CLI report parameter to limit a number of cross-link interference levels reported by the IAB relay node.

The description herein of illustrated implementations, including what is described in the Abstract, is not intended to be exhaustive or to limit the present disclosure to the precise forms disclosed. While specific implementations and examples are described herein for illustrative purposes, a variety of alternate or equivalent embodiments or implementations calculated to achieve the same purposes may be made in light of the above detailed description, without departing from the scope of the present disclosure, as those skilled in the relevant art will recognize.

What is claimed is:

1. A method for operating an integrated access and backhaul (IAB) node, the method comprising:

receiving data from a downlink (DL) transmission or an uplink (UL) transmission;

receiving radio resource control (RRC) signaling from a IAB donor node (DN), the RRC signaling to include configuration information with respect to reference signals of the IAB DN or one or more neighboring IAB nodes;

performing one or more measurements based on the reference signals of the IAB DN or the one or more neighboring IAB nodes while receiving the data; and transmitting one or more measurement results of the one or more measurements to the IAB DN.

2. The method of claim 1, wherein the receiving comprises receiving the data from a IAB DN DL transmission or a child node UL transmission.

3. The method of claim 1, wherein the one or more measurements comprise one or more Reference Signal Received Power (RSRP) measurements, one or more Ref-

19

erence Signal Received Quality (RSRQ) measurements, or one or more Signal to Interference plus Noise Ratio (SINR) measurements.

4. The method of claim 1, wherein the plurality of reference signals comprises a plurality of synchronization signals (SS) or a plurality of channel state information reference signals (CSI-RSs).

5. The method of claim 1, wherein the transmitting comprises transmitting the one or more measurement results through the RRC signaling.

6. The method of claim 1, further comprising generating a measurement report having the one or more measurement results, the measurement report including one or more cross-link interference levels that are associated with the IAB DN or the one or more neighboring IAB nodes.

7. The method of claim 1, wherein the transmitting comprises transmitting the one or more measurement results to a central node within the IAB DN.

8. An apparatus, comprising:

a memory to store configuration information with respect to a plurality of reference signals of an integrated access backhaul (IAB) donor node (DN) or one or more neighboring IAB nodes; and

a processor, coupled with the memory, configured to: receive data from a downlink (DL) transmission or an uplink (UL) transmission;

perform one or more measurements based on the plurality of reference signals of the IAB DN or the one or more neighboring IAB nodes while receiving the data; and

transmit one or more measurement results of the one or more measurements to the IAB node.

9. The apparatus of claim 8, wherein the processor is configured to receive the data from a IAB DN DL transmission or a child node UL transmission.

10. The apparatus of claim 8, wherein the one or more measurements comprise one or more Reference Signal Received Power (RSRP) measurements, one or more Reference Signal Received Quality (RSRQ) measurements, or one or more Signal to Interference plus Noise Ratio (SINR) measurements.

11. The apparatus of claim 8, wherein the plurality of reference signals comprises a plurality of synchronization signals (SS) or a plurality of channel state information reference signals (CSI-RSs).

12. The apparatus of claim 8, wherein the processor is configured to transmit the one or more measurement results through the RRC signaling.

20

13. The apparatus of claim 8, wherein the processor is further configured to generate a measurement report having the one or more measurement results, the measurement report including one or more cross-link interference levels that are associated with the IAB DN or the one or more neighboring IAB nodes.

14. The apparatus of claim 8, wherein the processor is configured to transmit the one or more measurement results to a central node within the IAB DN.

15. An integrated access and backhaul (IAB) node, comprising:

an interface configured to receive radio resource control (RRC) signaling from an IAB donor node (DN), the RRC signaling to include configuration information with respect to a plurality of reference signals of the IAB DN or one or more neighboring IAB nodes; and a processor, coupled with the interface, configured to: receive data from a downlink (DL) transmission or an uplink (UL) transmission;

perform one or more measurements based on the plurality of reference signals of the IAB DN or the one or more neighboring IAB nodes while receiving the data; and

transmit one or more measurement results of the one or more measurements to the IAB DN.

16. The IAB node of claim 15, wherein the processor is configured to receive the data from a IAB DN DL transmission or a child node UL transmission.

17. The IAB node of claim 15, wherein the one or more measurements comprise one or more Reference Signal Received Power (RSRP) measurements, one or more Reference Signal Received Quality (RSRQ) measurements, or one or more Signal to Interference plus Noise Ratio (SINR) measurements.

18. The IAB node of claim 15, wherein the processor is configured to transmit the one or more measurement results through the RRC signaling.

19. The IAB node of claim 15, wherein the configuration information is further with respect to a plurality of reference signals of a plurality of neighboring IAB nodes.

20. The IAB node of claim 15, wherein the processor is further configured to generate a measurement report having the one or more measurement results, the measurement report including one or more cross-link interference levels that are associated with the IAB DN or the one or more neighboring IAB nodes.
