ABSTRACT

A screening device for testing saliva for the presence of certain constituents. The device has a D-shaped profile when viewed from above and includes a first wall with planar front face through which all of the test strips are viewed and a curved rear second wall. The device also includes a floor surface with an uppermost portion extending from the rear wall to a lowermost portion at the first wall such that saliva squeezed from a sampler at a location between the uppermost portion and the lowermost portion flows downwardly to the test strips.

[0001] This application is a Continuation of U.S. patent application Ser. No. 16/875,583 filed May 15, 2020, which is a Continuation of U.S. patent application Ser. No. 16/008,720 filed Jun. 14, 2018, now U.S. Pat. No. 10,744,507, which is a Continuation of U.S. patent application Ser. No. 14/834,534 filed Aug. 25, 2015, which is a Continuation of U.S. patent application Ser. No. 14/079,558 filed Nov. 13, 2013, which claims the benefit of U.S. Provisional Patent Application No. 61/725,898 filed Nov. 13, 2012, the disclosures of which are hereby incorporated by reference in their entirety.

FIELD OF THE INVENTION

[0002] This application is directed generally to devices and methods for analysis of the presence of constituents in fluids, and more specifically to devices and methods for analysis of the presence of constituents in bodily fluids for drug test screening.

BACKGROUND OF THE INVENTION

[0003] Various drug screening devices are known for testing a sample of bodily fluids for the presence of certain constituents. These devices typically include a container for receiving a bodily fluid from a delivery device, and a plurality of reagent test strips arranged to contact the bodily fluid, with each test strip being sensitive to a particular constituent of interest. The targeted constituents for screening can range from controlled substances such as alcohol and marijuana to illegal substances such as cocaine and methamphetamines.

[0004] For screening purposes, it is desirable to test for as many constituents as possible with a single sample, so as to reduce the nuisance factor associated with obtaining multiple bodily fluid samples. This is particularly a problem with saliva where sufficient quantities for multiple tests is problematic. Accordingly, many devices are intended to distribute the sampled bodily fluid among as many test strips as reasonably possible. This is typically accomplished by arranging a plurality of test strips on each of several sides of the container.

[0005] Problems associated with a plurality of test strips arrayed on several sides of a test container include maldistribution of bodily fluid samples to the various test strips and the necessity to inspect more than one side of the container to determine the screening result. A screening device that addresses these maladies would be welcomed.

SUMMARY OF THE INVENTION

[0006] Various embodiments of the invention include a device and method for adequately distributing a sample of bodily fluid among a plurality of test strips and preventing maldistribution of sampled fluid that can lead to an invalid test result, all while displaying the test results on a single face of the screening device. Certain embodiments also enable a slight and passive pressurization of a sampling chamber to augment the wicking or capillary action of the sampled fluid along the test strips.

[0007] One problem with the prior art arrangement of having a plurality of test strips arrayed on several sides of a test container is that the arrangement is prone to operator error. Persons conducting the screening test often hold the screening device in their hand while awaiting the test results. While holding the device, there is a tendency to tilt the proximal face of the device backward for easier reading. Unfortunately, this can cause the bodily fluid under test to pool at the bottom of the distal face of the testing device, thus starving the test strips that are disposed on the proximal face. The result is an invalid test for the constituents represented by the test strips on the proximal face.

[0008] Structurally, various embodiments of the invention include a container or cup having a first or “viewing” side through which all of the test strips can be viewed. The bottom of the cup is inclined and intersects the viewing side along a junction line that constitutes the lowest portion of the cavity within the cup where the bodily fluid collects. The test strips are oriented so that the detection end proximate the junction line for in contact with the bodily fluid that collects at the low portion of the cavity. By this arrangement, all of the test strips can be inspected by viewing a single surface of the cup, and the inclined surface of the bottom of the cup directs all of the bodily fluid into contact with the detection end of the test strips. Furthermore, the angle of the intersection between the bottom and the viewing side can be steep enough to counter a substantial holding angle induced by the operator.

[0009] In certain embodiments, a three-dimensional gasket is implemented to provide certain sealing and pressurization advantages. The three-dimensional gasket can be made of a soft, pliable material to provide a sealing surface between the gasket and the cup and to provide a seal between a sampling stem that is inserted through the gasket. The pliable material can also cause the three-dimensional gasket to act as a diaphragm; when the sampling stem is inserted into the three-dimensional gasket, the displaced air causes the three-dimensional gasket to expand (as would a diaphragm), thereby causing the air contained by the three-dimensional gasket to become slightly pressurized. The pressurization can assist in the diffusion of the bodily fluid into the test strips, thus augmenting the capillary action between the bodily fluid and the test strip.

[0010] The device can also provide barriers between the detection ends of adjacent test strips to prevent more absorbent or faster absorbing test strips from drawing test fluid away from less absorbent or slower absorbing test strips.

[0011] A feature and advantage of embodiments of the invention is a specimen sampling device for saliva where the saliva is absorbed in a sponge, is squeezed into a saliva pathway of a specimen container, the saliva pathway is pressurized urging the saliva into engagement with a plurality of sample test strips. In embodiments a vent may be provided downstream of where the saliva engages the test strips. In embodiments, the plurality of test strips are each positioned in a plurality of recesses in a row, the recesses having an overfill level whereby fluid that overflows one recess flows into an adjacent recess. In embodiments, the pressurization may be provided by a stem attached to the sponge, the stem having a sliding plunger member. In embodiments the pressurization may be provided by a separate manual squeeze or push pump as part of the specimen sampling device.

[0012] Another feature and advantage of embodiments of the invention is a specimen sampling device for saliva where the saliva is absorbed in a sponge, is squeezed into a saliva pathway of a specimen container, the saliva pathway leading to a plurality of sample test strips aligned in a linear row of at least 8 strips positioned on a substantially planar wall and exposed to be readable through one or more transparent regions, the strips having a sample receiving end that is placed at the bottom of an inclined plate in the saliva pathway. In some such embodiments, embodiments may have a gasket sealingly enclosing a specimen chamber including the inclined plate and a row of recesses into which the at least 8 strips extend. In some such embodiments, a curved, wall is positioned opposite the planar wall.

[0013] An additional feature and advantage of embodiments of the invention is a specimen sampling device for saliva where the saliva is absorbed in a sponge, is squeezed into a saliva pathway of a specimen container, the saliva pathway leading to a plurality of sample test reservoirs, each with test strip extending therein, a gasket with a separate aperture for each respective test strip, the gasket providing sealing between the saliva pathway including and the reservoirs and regions of the container above the saliva pathway thereby preventing unintended migration of the saliva upward.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION

[0026] Referring to FIG. 1, a testing assembly 20 for screening bodily fluids for the presence of certain constituents is depicted in an embodiment of the invention. The screening device includes a container or cup 22, a test strip and sampling stem holder 24 (hereinafter “holder 24”), a three-dimensional gasket 26 and a sampling stem 28.

[0027] Referring to FIGS. 2 and 3, the cup 22 is depicted in isolation in an embodiment of the invention. The cup 22 includes a plurality of sides 32 and 34 that extend upward

from a containment bottom 38 to form a continuous upper edge 36, the sides 32, 34 and containment bottom 38 defining a cavity 42. The sides 32 and 34 can also extend below the containment bottom 38 to establish a base portion 40 with a lower edge 41 registers the testing assembly 20 in an upright position. A first of the sides (side 32 in FIGS. 2 and 3) can be substantially planar. In one embodiment, the containment bottom 38 defines an inclined surface 44 that intersects the plurality of sides 32 and 34. The inclined surface 44 intersects the first side 32 along a junction line 46, defining an acute angle θ between the first side 32 and the inclined surface 44. The junction line 46 is the lowermost extremity of the cavity 42 when the cup 22 is in the upright position.

[0028] While the inclined surface 44 is depicted as being substantially planar, it is noted that the inclined surface 44 is not limited to a planar configuration. For example, the inclined surface could also be convex, with a steeper slope at the junction line 46 than at other locations on the inclined surface. Alternatively, the inclined surface could be concave, with a more gradual slope at the junction line 46 than at other locations.

[0029] In one embodiment, the containment bottom 38 can further include a pedestal portion 48 that extends from the inclined surface 44 into the cavity 42. The pedestal portion 48 can include a top face 49 having a perimeter 50. A securing structure 51, such as a point or barb (as depicted in FIG. 3), can be included on or as part of the top face 49 of the pedestal portion.

[0030] Various embodiments of the cup 22 can also include a syringe access port 53 located proximate a lower corner of the cup 22. The syringe access port comprises a region where the thickness of the cup 22 is thinned to enable manual puncturing with a syringe.

[0031] The cup 22 can be fabricated from a variety of materials available to the artisan, including but not limited to polycarbonate, styrene-butadiene copolymers (SBCs) such as K-RESIN, and clear styrene.

[0032] Referring to FIGS. 4 and 5, the holder 24 is depicted in isolation in an embodiment of the invention. The holder 24 includes a cap portion 52 having an access port 54 formed therein. The holder 24 also includes a through passage structure 56 that defines a through passage 58 that passes through the holder 24. The through passage structure 56 includes a proximal end 60 and a distal end 62, each being concentric about an insertion axis 64. The proximal end 60 of the through passage structure 56 includes the access port 54. The through passage structure 56 can comprise a hollow tube that depends from the cap portion 52 (as depicted), or a bore that extends through a substantially solid holder 24.

[0033] The holder 24 also includes a planar face 66 that extends downward from the cap portion 52. The planar face 66 includes a plurality of parallel ribs 68 that define a plurality of elongate channels 72. The elongate channels 72 each define a channel axis 74.

[0034] The holder 24 can be fabricated from a variety of materials available to the artisan, including but not limited to polycarbonate, styrene and acrylonitrile butadiene styrene (ABS).

[0035] Referring to FIGS. 6 and 7, the three-dimensional gasket 26 is depicted in an embodiment of the invention. The three-dimensional gasket 26 includes a passage extension structure 82 that defines an extended passage 84 and a

diaphragm portion **86** that depends from and extends radially outward from the passage extension structure **82**. A perimeter structure **88** of the three-dimensional gasket **26** surrounds and depends from the diaphragm portion **86**, the perimeter structure **88** having a lower face **92** that extends below the diaphragm portion **86**. The three-dimensional gasket can also include a notch **91** that, upon assembly, aligns with the syringe access port **53** of the cup, enabling easy access to the chamber **150**. The three-dimensional gasket **26** can also include guide tabs **93** that assist in guiding, registering and seating the three-dimensional gasket into the holder **24** during assembly.

[0036] The perimeter structure **88** includes a front portion **90** having an outer face **94** and an inner face **96**. The outer face **94** is adapted to contact an inner surface of the first side **32** of the cup **22**. In one embodiment, the inner face **96** includes a plurality of riblets **102** that extend inwardly, in the general direction of the extended passage **84**. The riblets **102** can include lower surfaces **104** configured to engage the inclined surface **44** of the containment bottom **38**. In one embodiment, the three-dimensional gasket **26** is fabricated from a soft, pliable material such as polyvinylchloride (PVC) or neoprene.

[0037] Referring to FIG. 8, a test strip **110** is depicted. The test strip **110** includes a detection end **112** and a non-detection end **113**. The detection end **112** wicks fluid to a sensing zone **114** via capillary action through an absorbent material **116**. The sensing zone **114** is configured with reagents that react and provide a visual indication when a certain constituent is present in the bodily fluid. A width **118** of the test strip **110** is dimensioned to slidably engage a corresponding one of the elongate channels **72**. In the depicted embodiment, the test strip **110** is characterized as having increased thickness at both the detection and non-detection ends **112** and **113** due to the presence of the absorbent material **116**.

[0038] Referring to FIG. 9, the sampling stem **28** is depicted in an embodiment of the invention. The sampling stem **28** is characterized as having a proximal portion **132** and a distal portion **134**. The proximal portion **132** can include a handle or knob **135** for handling and manipulation of the sampling stem **28**. Certain aspects of the sampling stem **28** are depicted and described at U.S. Patent Application Publication No. 2012/0094303 to Engel et al., which is hereby incorporated by reference herein except for express definitions contained therein. The sampling stem **28** can be fabricated from a variety of materials available to the artisan, including but not limited to polycarbonate, styrene-butadiene copolymers (SBCs) such as K-RESIN, and clear styrene.

[0039] In one embodiment, the proximal portion **132** includes structure that is complementary with structure on the cap portion **52** for securing the sampling stem **28** in a fixed position along the insertion axis **64** relative to the cap portion **52**. In the depicted embodiment, the complementary structures comprise a female threaded structure **136** proximate the access port **54** of the cap portion **52** of the holder **24** and a male threaded portion **138** proximate the proximal portion **132** of the sampling stem **28**. Other complementary structures could also be utilized, including a detent-and-groove snap fit structure a bayonet-style lock or a clasp.

[0040] In one embodiment, the sampling stem **28** and the access port **54** are configured to provide a ratchet-and-pawl mechanism for rotationally locking the sampling stem **28** relative to the holder **24**. In the depicted embodiment, the

sampling stem **28** includes a pawl **142** distal to the male threaded portion **138**. The pawl **142** is configured to engage ratchet notches **144** (FIG. 4).

[0041] The distal portion **134** of the sampling stem **28** includes a sampling swab **140** that is mounted to a collar **141**. In one embodiment, the collar **141** is comprised of a transparent material to enable ultraviolet activation of bonding agents that are placed between the sampling swab **140** and the collar **141**. The distal portion **134** is configured for insertion through the through passage **58** and extended passage **84**. In one embodiment, the collar **141** is sized to provide a sliding seal between the collar **141** and the extended passage **84**. Also, in one embodiment, the through passage **58** as well as the extended passage **84** is tapered (i.e., has a larger diameter at the proximal end than at the distal end) in order to guide the distal portion **134** without causing it to bind, but still affecting a seal as the collar **141** approaches its final axial location along the insertion axis **64**.

[0042] Referring to FIGS. 10 through 12, the testing assembly **20** is depicted in various states of assembly. In assembly, the three-dimensional gasket **26** is coupled to the bottom of the holder **24** and the test strips inserted into the respective elongate channels **72** so that the detection end extends into the extended channel. The holder **24** and three-dimensional gasket **26** assembly, with test strips **110** loaded in the channels **72**, is inserted into the cup **22** such that the three-dimensional gasket **26** is disposed between the holder **24** and the containment bottom **38**. The cap portion **52** of the holder **24** is brought into contact with and joined to the continuous upper edge **36** of the cup **22** (FIG. 12). Any joining or bonding method available to the artisan can be utilized to join the cap portion **52** to the cup **22**, including gluing, fusion or sonic welding, or a detent-and-groove snap fit engagement.

[0043] After assembly, the orientation of the elongate channels **72** of the holder **24** are such that the channel axes **74** are substantially perpendicular to the junction line **46**. The extended passage **84** is in substantial alignment with the through passage **58** and is substantially concentric about the insertion axis **64**. The pedestal portion **48** can extend part-way into the extended passage **84**. The perimeter **50** of the top face **49** of the pedestal portion **48** can be normal to the insertion axis **64**, and can also be concentric about the insertion axis **64**.

[0044] The three-dimensional gasket **26** can be compressed between the holder **24** and the inclined surface **44** of the containment bottom such that the lower face **92** of the perimeter structure **88** is in sealing contact with the inclined surface **44** of the containment bottom **38**. The outer face **94** of the front portion **90** of the perimeter structure **88** can also be in sealing contact with the interior of the first side **32** of the cup **22** just above the junction line **46**. In this way, a chamber **150** is defined, bounded by the diaphragm portion **86**, the perimeter structure **88** and the inclined surface **44**. The chamber **150** is accessible via the extended passage **84**.

[0045] Each of the riblets **102** of the three-dimensional gasket **26** extend into the chamber **150** and are in substantial alignment with a corresponding one of the ribs **68** of the planar face **66** of the holder **24** to form a plurality of channel extensions **152**. Engagement of the lower surfaces **104** of the riblets **102** with the inclined surface **44** creates a plurality of pockets **154** (partially depicted in FIG. 7) that are proximate the junction line **46**. In one embodiment, the detection end **112** of a given strip **110** accesses the channel extensions **152**

and pockets 154 through slots 156 (FIG. 6) formed proximate the front portion 90 of the perimeter structure 88 of the three-dimensional gasket 26. The slots 156 can be dimensioned so that the absorbent material 116 of the detection end 112 of an occupying test strip 110 is in light contact with the interior of the slot 156. During assembly, the light contact between the test strip 110 and the slot 156 can be enough to hold the test strip 110 in its respective elongate channel 72 until the assembly operation is complete.

[0046] In operation, the sampling swab 140 of the sampling stem 28 is saturated with bodily fluid to be analyzed (e.g., saliva from a person being screened for drug use). The distal portion 134 of the sampling stem 28 is then inserted into the access port 54 and slid through the through passage 58 of the holder 24 and into the extended passage 84 of the three-dimensional gasket 26. The sampling swab 140 is thereby brought into contact with the pedestal portion 48. The sampling stem 28 is further pushed into the access port 54 until the male threaded portion 138 of the sampling stem 28 is engageable with the female threaded structure 136 of the access port 54 (or other complementary coupling structures become engageable). The male threaded portion 138 is then threaded into the female threaded structure 136 until the proximal portion 132 of the sampling stem 28 is fully engaged within the access port 54 (e.g., by registration of the knob 135 against an upper periphery of the access port 54).

[0047] For embodiments utilizing the ratchet-and-pawl mechanism, the threading action (rotation of the sampling stem 130) causes the pawl 142 to engage with the ratchet notches 144. This prevents the sampling stem 28 from rotating out of the access port 154, thus locking the sampling stem 28 in a fixed axial position along the insertion axis 64.

[0048] The threading action between the proximal portion 132 and the access port 54 also causes the sampling swab 140 to be further extended into the extended passage 84 of the three-dimensional gasket 26, causing the sampling swab 140 to be compressed against the pedestal portion 48 (when present) or, more generally, against the containment bottom 38. The securing structure 51 secures the sampling swab 140, thereby inhibiting the swab 140 from sliding laterally relative to the insertion axis 64. By securing the sampling swab 140, more efficient extraction of bodily fluid from the sampling swab 140 is attained during compression.

[0049] The compression acts to wring the bodily fluid out of the sampling swab 140, which then flows over the pedestal portion 48, down the inclined surface 44 and along saliva pathways 160 (FIG. 12) to pool along the inner face 96 of the perimeter structure 88 proximate the lower most portion of the cavity 42, i.e., into the pockets 154 located proximate the junction line 46). The pockets 154 that are nearest the center of the three-dimensional gasket 26 (i.e., more proximate the insertion axis 64) will tend to receive more fluid initially than the pockets 154 located near the extreme corners of the three-dimensional gasket 26. The riblets 102 can be dimensioned so that the pockets 154 accept only an amount needed to adequately activate the corresponding test strip 110. Accordingly, as the bodily fluid flows into the nearest of the pockets 154, these pockets will overflow and cascade over the riblets 102 as the pockets 154 become successively filled. Given an ample quantity of bodily fluid, all of the pockets 154 should receive sufficient bodily fluid for analysis. In one embodiment, the riblets 102

are sized and spaced so that a dozen pockets 154 can hold 1 ml of fluid and the sampling swab 140 sized to accept 20 ml of bodily fluid.

[0050] The depicted embodiments present twelve elongate channels 72 for housing twelve test strips 110; however, configurations having more or less channels 72 can also be implemented, depending on the quantity of fluid available for analysis. Typically, the number of elongate channels 72 ranges from 6 to 15.

[0051] While the cascading action between the pockets 154 can take several seconds, the absorption by the test strips 110 is on the order of minutes. Therefore, the riblets 102 prevent more absorbent or faster absorbing test strips from drawing test fluid away from less absorbent or slower absorbing test strips, thus providing better and more predictable analysis results.

[0052] The insertion of the distal portion 134 of the sampling stem 28 into the extended passage 84 also acts to pressurize the chamber. The three-dimensional gasket 26 can be made of a soft, pliable material, so that the perimeter structure 88 provides a seal with the inclined surface 44, and a seal is also affected between the collar 141 and the extended passage 84 as the collar 141 of the sampling stem 28 reaches its final position within the extended passage 84. Thus, as the distal portion 134 of the sampling stem 28 moves into its final position, air is displaced and pushed into the chamber 150. The pliable material can also cause the diaphragm portion 86 to flex, thereby causing the air contained by the three-dimensional gasket 26 to become slightly pressurized. While some venting may occur between these sealed surfaces, as well as through the absorbent material 116 deposited in the slots 152, the pressurization can still assist in the diffusion of the bodily fluid into the absorbent material 116, thus augmenting the capillary action between the bodily fluid and the test strip 110.

[0053] All of the features disclosed in this specification (including any accompanying claims, abstract and drawings), and/or all of the steps of any method or process so disclosed, can be combined in any combination, except combinations where at least some of such features and/or steps are mutually exclusive.

[0054] Each feature disclosed in this specification (including any accompanying claims, abstract and drawings) can be replaced by alternative features serving the same, equivalent or similar purpose, unless expressly stated otherwise. Thus, unless expressly stated otherwise, each feature disclosed is one example only of a generic series of equivalent or similar features. For purposes of interpreting the claims for the present invention, it is expressly intended that the provisions of Section 112, sixth paragraph of 35 U.S.C. are not to be invoked unless the specific terms “means for” or “step for” are recited in the subject claim.

1. A device for testing a liquid sample, the device comprising:

- a cup defining an interior cavity, the cup having a planar forward wall and a rearward wall;
- a holder having an insertion portion positioned in the cup and a cap portion;
- the cap portion of the holder defining an access port, and the insertion portion has a through passage structure extending from a bottom of the cap portion into the interior cavity of the cup, the through passage structure being in register with the access port;

the holder further including a female threaded structure proximate the access port of the cap portion;
a swab compression structure;
a plurality of test strips arranged in parallel to each other adjacent the planar forward wall of the cup; and
a sampling stem insertable through the access port of the cap, the sampling stem having a sampling swab at a distal portion thereof and male threaded portion at a proximal portion thereof,
wherein the male threaded portion of the sampling stem engages the female threaded portion of the holder such that rotation of the sampling stem in one rotational direction causes axial movement of the sampling stem such that the sampling swab will be compressed against the swab compression structure.

2. A device for testing a liquid sample as set forth in claim 1, wherein the holder and sampling stem together comprise a ratchet and pawl mechanism operative to lock the sampling stem against backward rotation relative to the holder.

3. A device for testing a liquid sample as set forth in claim 2, wherein the ratchet and pawl mechanism comprises a plurality of ratchet elements on the holder and at least one pawl on the sampling stem.

4. A device for testing a liquid sample as set forth in claim 2, wherein the sampling stem comprises a knob located at the proximal portion thereof.

5. A device for testing a liquid sample as set forth in claim 4, wherein the knob has a knurled outer surface for gripping by a user.

6. A device for testing a liquid sample as set forth in claim 4, wherein the ratchet and pawl mechanism comprises at least one pawl adjacent to the knob.

7. A device for testing a liquid sample as set forth in claim 6, wherein the at least one pawl is situated between the knob and the male threaded portion along an axis of the sampling stem.

8. A device for testing a liquid sample as set forth in claim 6, wherein the distal portion of the sampling stem comprises a collar at the distal portion thereof that provides a seal with an inner surface of the through passage structure.

9. A device for testing a liquid sample as set forth in claim 1, wherein the cup comprises a base portion with a lower edge that registers the cup in an upright position.

10. A device for testing a liquid sample as set forth in claim 1, wherein the rearward wall is curved.

11. A device for testing a liquid sample as set forth in claim 1, wherein the swab compression structure comprises a pedestal.
