(57) **ABSTRACT**

The embodiments disclose an asset management database system including a database system server configured to track the user asset transactions, at least one computer coupled to the database system server configured to allow a user access to the asset transactions and activities, a plurality of distributed databases coupled to the database system server configured to collectively manage and interlink data of four fundamental components, a file management system coupled to the database system server configured to maintain and identify the four fundamental components data, at least one processor coupled to the database system server configured to match the four fundamental components in the file management system, at least one communication device wirelessly coupled to the database system server, and a digital device app wirelessly coupled to the communication device.

DATABASE AND FILE MANAGEMENT TRANSACTION TRACKING SYSTEM

CROSS-REFERENCE TO RELATED APPLICATIONS

This patent application is a Continuation and claims priority to United States patent application entitled: "DATABASE AND FILE MANAGEMENT TRANSACTION TRACKING SYSTEM", U.S. Ser. No. 18/394,157 as filed on Dec. 22, 2023 filed by Sadeil James Lewis, which is a Continuation-in-part and claims priority to United States patent application entitled: "STAKED ACCOUNT PAYMENT PROCESS AND DEVICES", U.S. Ser. No. 17/991,957 as filed on Nov. 22, 2022 filed by Sadeil James Lewis, all the U.S. patent applications being incorporated herein by reference.

BACKGROUND

Distributed databases are used for blockchain transactions and holding assets for staked assets. Change of ownership is only one aspect of blockchain transactions. Organization and access to the distributed databases can restrict asset holders to limited functions and ability to receive updated data regarding their transactions. What is needed is a secure database system that broadens the services and information access available to the asset holders and other interested parties.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows for illustrative purposes only an example of a database system server of one embodiment.

FIG. 2 shows for illustrative purposes only an example of an Asset Bound Tokens (ABTs) app of one embodiment.

FIG. 3 shows for illustrative purposes only an example of ABT transactions and asset-related activities databases of one embodiment.

FIG. 4 shows a block diagram of an overview of a staked account payment process and devices of one embodiment.

FIG. 5 shows a block diagram of an overview flow chart of staked account payment process of one embodiment.

FIG. 6 shows a block diagram of an overview of blockchain transactions of one embodiment.

FIG. 7 shows for illustrative purposes only an example of an asset management social network platform of one embodiment.

FIG. 8 shows a block diagram of an overview of a blockchain staked account of one embodiment.

FIG. 9 shows a block diagram of an overview of meta-verse staked value assets transactions of one embodiment.

FIG. 10 shows a block diagram of an overview of staked value assets investments of one embodiment.

FIG. 11 shows a block diagram of an overview of lifestyle expenses of one embodiment.

FIG. 12 shows a block diagram of an overview of blockchain transactions of one embodiment.

FIG. 13 shows for illustrative purposes only an example of account owner blockchain transfers of one embodiment.

FIG. 14 shows a block diagram of an overview of a NFT gallery metaverse of one embodiment.

FIG. 15 shows a block diagram of an overview of a real estate NFT marketplace of one embodiment.

FIG. 16 shows a block diagram of an overview of fractional ownership of one embodiment.

2

FIG. 17 shows a block diagram of an overview of selling the property's NFT of one embodiment.

FIG. 18 shows a block diagram of an overview of a personal virtual world of one embodiment.

5 FIG. 19 shows a block diagram of an overview of attending virtual events of one embodiment.

FIG. 20 shows a block diagram of an overview of decentralized, interoperable environment of one embodiment.

10 FIG. 21 shows a block diagram of an overview of blockchain staked assets of value escrow accounts of one embodiment.

FIG. 22 shows a block diagram of an overview of blockchain staked assets of value derivative contracts of one embodiment.

FIG. 23 shows a block diagram of an overview of a blockchain asset management system of one embodiment.

FIG. 24 shows a block diagram of an overview of ABT features of one embodiment.

FIG. 25 shows a block diagram of an overview of asset bound tokens that facilitate market liquidity of one embodiment.

FIG. 26 shows a block diagram of an overview of asset bound tokens of one embodiment.

FIG. 27 shows a block diagram of an overview of a meal prep ABT of one embodiment.

FIG. 28 shows a block diagram of an overview of a meal prep ABT process of one embodiment.

FIG. 29 shows a block diagram of an overview of open share of one embodiment.

FIG. 30 shows a block diagram of an overview of verified retail entities of one embodiment.

FIG. 31 shows a block diagram of an overview of Interoperability of one embodiment.

FIG. 32 shows a block diagram of an overview of a social credit score of one embodiment.

FIG. 33 shows a block diagram of an overview of an algorithmic asset bound token of one embodiment.

FIG. 34 shows a block diagram of an overview of ABT market security of one embodiment.

FIG. 35 shows a block diagram of an overview of decentralized identifier data of one embodiment.

FIG. 36 shows a block diagram of an overview of an ABT land example of one embodiment.

FIG. 37 shows a block diagram of an overview of data for education of one embodiment.

FIG. 38 shows a block diagram of an overview of smart contracts of one embodiment.

FIG. 39 shows a block diagram of an overview of web 3 applications of one embodiment.

FIG. 40 shows a block diagram of an overview of a global supply chain of one embodiment.

FIG. 41 shows a block diagram of an overview of transaction fees of one embodiment.

FIG. 42 shows a block diagram of an overview of ABT creators of one embodiment.

FIG. 43 shows a block diagram of an overview of an ABT customer data platform of one embodiment.

FIG. 44 shows a block diagram of an overview of data modeling of one embodiment.

FIG. 45 shows a block diagram of an overview of transaction studio of one embodiment.

FIG. 46 shows a block diagram of an overview of segmenting data of one embodiment.

FIG. 47 shows a block diagram of an overview of wallet messages of one embodiment.

3

FIG. 48 shows a block diagram of an overview of file integrations automations of one embodiment.

FIG. 49 shows a block diagram of an overview of assetflow journey builder of one embodiment.

FIG. 50 shows a block diagram of an overview of data insights of one embodiment.

DETAILED DESCRIPTION OF THE INVENTION

In a following description, reference is made to the accompanying drawings, which form a part hereof, and in which is shown by way of illustration a specific example in which the invention may be practiced. It is to be understood that other embodiments may be utilized and structural changes may be made without departing from the scope of the present invention.

General Overview

It should be noted that the descriptions that follow, for example, in terms of database system and method for ABT token management and transaction tracking is described for illustrative purposes and the underlying system can apply to any number and multiple types ABT tokens. In one embodiment of the present invention, the database system and method for ABT token management and transaction tracking can be configured using file management system. The database system and method for ABT token management and transaction tracking can be configured to include multiple database devices and can be configured to include wallet repositories using the present invention.

FIG. 1 shows for illustrative purposes only an example of a database system server of one embodiment. FIG. 1 shows a database system server 100 that controls the database system that employs a well-structured data model, comprising four fundamental components that collectively manage and interlink data seamlessly. The four fundamental components include Token Holder Records; Wallet Repositories; Token Attribute Repositories; and Asset Management Modules. The database system server 100 is accessed by a user 110 on the user computer 120 having an asset bound tokens (ABTs) app 130.

The database system server 100 is coupled to databases that collectively manage and interlink data seamlessly 140. The databases include a token holder records database 160, wallet repositories database 162, token attribute repositories database 164, and asset management modules database 166. The database system server 100 coupled databases further include processors to identify and match the four fundamental components in the file management system 170 of one embodiment

FIG. 2 shows for illustrative purposes only an example of an Asset Bound Tokens (ABTs) app of one embodiment. FIG. 2 shows a user mobile device 210 having the asset bound tokens (ABTs) app 130. The asset bound tokens (ABTs) app 130 is used by the user 110 of FIG. 1 to report ABT transactions and asset-related activities 220. The asset bound tokens (ABTs) app 130 is wirelessly coupled to a network server 140 to communicate with the database system server 100. The allows the user 110 of FIG. 1 to record ABT transactions and asset-related activities 220 on the token holder records database 160, wallet repositories database 162, token attribute repositories database 164, asset management modules database 166, and file management system 170. The network server 215 and the database system

4

server 100 include at least one processor used to match files with database related data 230 of one embodiment.

FIG. 3 shows for illustrative purposes only an example of ABT transactions and asset-related activities databases of one embodiment. FIG. 3 shows the database system server 100 wirelessly linked to the user 110 computer 120 and the asset bound tokens (ABTs) app 130. The user 110 computer 120 allows the user to track the ABT transactions and asset-related activities 132. For example, the token holder records database 160 stores token holder records form an integral part of the data model, wherein each token holder record is uniquely identified by a token holder connect key and/or token holder connect id and these identifiers play a crucial role in the precise identification and management of individual token holders within the database system 300. The wallet repositories database 162, wherein the wallet repositories utilize a distinct identification method, known as the wallet repository key and/or wallet ID, these identifiers are for accurate tracking and efficient management of wallet-related data, including transactions and holdings 310. The token attribute repositories database 164 storing the token attribute repositories are used to organize and access attributes associated with tokens, the tokens are identified using a unique token attribute repository key and/or token attribute repository ID, enabling structured management of token-related data 320. The asset management modules database 166 stores asset management modules, which are configured for efficiently managing various assets represented by ABTs. these modules interact seamlessly with the other components to facilitate transactions and asset-related activities 330 of one embodiment.

FIG. 4 shows a block diagram of an overview of a staked account payment process and devices of one embodiment. FIG. 4 shows a user that owns wallet 400 that can follow, utilize and/or service staked assets 402 in a staking pool earns from pooled staked asset activities such as following, utilizing, and/or servicing staked assets, etc. 430. The user wallet 400 can purchase, transfer and create assets 406. Assets of value 405 are stored on blockchain staked account (wallet). The wallet also manages the public-private key pair and the blockchain address to provide a unique identity for network nodes/validators so they can securely interact with the network. The user can create, service, follow, utilize, etc. using a blockchain staked account. The blockchain staked account can serve as a treasury for any user and is not limited.

The user wallet 400 opens a blockchain staked account by staking assets 410 to earn interest on the assets of value 405 to pay expenses and make charitable donations to reduce income tax expenses. A blockchain staked account 410 can also behave as a treasury for governments, corporations, or institutions. The user wallet 400 can stake assets of value into the blockchain staked account. The user wallet 400 can create, purchase and/or assign assets of the blockchain staked account to a staking pool 420. The user wallet can also utilize, follow, and/or service staked assets in the staking pool 430 on the blockchain staked account. The user wallet may also unfollow 430, archive, destroy, and/or transfer 409 from the blockchain staked account. The user can unstake 408 assets from the blockchain staked account.

A staking pool earns from pooled staked asset activities 430. A portion of the pooled staked asset activities earnings is paid to the blockchain staked account user 435. The portion of earnings received by the user wallet 400 is new staked asset 440 adding appreciation to the assets of value 405. A new staked asset 440 can include assets including fixed assets, buildings, machinery or furniture, education,

5

clothes and/or original assets, for example a car or truck. In another embodiment a new staked asset **440** can include new staked currency. A user can purchase this new staked currency.

Another pooled staked asset activity is servicing, following, and/or utilizing staked assets. Servicing entities are part of the staking pool for users to stake their assets with them. The entities servicing an asset can be, for example, a distributor, shipper, retail store, broker, digital entity, gaming entity, metaverse, and the like, who can be reviewed and verified. The verified servicing entities may receive more yield due to exceeding servicing standards and/or credibility servicing staked assets. Verified servicing entities should increase the value of an asset therefore receiving more yield.

The user wallet **400** apportions a part of an APY/APR yield to be retained in the assets of value **405** as an addition to the staking pool to create an auto compounding yield **455** with the new staked currency **440**. The user then can utilize the remaining part of the new staked currency **440**.

The user wallet **400** can use new staked currency to pay user expenses and make purchases **460** without diminishing the assets of value **405**. The net result is that the assets of value **405** is continually growing, the user is not incurring any costs associated with financial transactions, and the user's expenses are being paid and purchases are being made with a portion of the new staked currency **440** without withdrawing any of the assets of value **405** of one embodiment.

New staked asset allows a user to stake any asset of value. A user stakes an asset, and a new staked asset is created. Most entities will limit their yield to an asset(s) of their choice and have exclusive members. The more loyalty brand recognition, and pool staked asset activities the user gives "above entity", the user's yield could increase, stay the same or decrease overtime. Users can receive yield if they subscribe to assets with utility subscriptions. Any wallet can participate in pool staked activities. Every time a user utilizes an asset owners' asset, the asset owners created content will index higher in user's personal. This can also be used as a social credit score **445** system.

FIG. **5** shows a block diagram of an overview flow chart of staked account payment process of one embodiment. FIG. **5** shows the user wallet **400** of FIG. **4** opening a blockchain staked account with a private code to make transfers and a public code to receive transfers of a new staked asset **500**. Opening a blockchain staked account includes staking assets of value into the blockchain staked account including currency, cryptocurrency, expenses, debts, non-fungible tokens, and other assets of value **510**. The staked account assets are represented with Asset Bound Tokens (ABTs) and a social element to form tokenized assets. Unstaking assets of value from the blockchain staked account are returned to the user wallet **512**.

The user wallet **400** of FIG. **4** continues with optionally pledging staked assets with interest paying and/or servicing entities **520**. Users follow staked asset to utilize staked asset(s) increasing attention and yield of asset(s) **525**. Interest paying entities use a staking pool for staked asset activities to earn fees, interest and other funds without transferring any of the staked pool assets. The interest paying entities pay a portion of the earnings to those with utilized pledged staked assets in the pool. The user wallet **400** of FIG. **4** is receiving interest payments in an asset of paying entities and/or user's choice to accumulate an annual yield classified as a new staked asset **530**. Servicing entities receive a portion of earnings of those with utilized pledged staked assets they are servicing from the blockchain **535**.

6

The staked assets form a portion of the interest received for compounding interest payments to increase the yield **540**. The user wallet **400** of FIG. **4** is making blockchain payments with the balance of the staked new assets interest comprising at least company expenses, lifestyle expenses, debts, and charitable donations **550**. The user wallet **400** of FIG. **4** increases the value of the assets of value by making blockchain purchases with the staked new assets comprising at least investments and metaverse transactions **560**. Servicing entities receive a portion of those with utilized pledged staked assets they are servicing from the blockchain **570**. Users follow and/or subscribe staked assets to utilize staked asset(s) increasing attention and yield of asset(s) of one embodiment.

FIG. **6** shows a block diagram of an overview of blockchain transactions of one embodiment. FIG. **6** shows the APY/APR yield **602** with a portion being used for adding an auto compound yield **455**. Another portion of the APY/APR yield **602** is used for blockchain transactions **600** and ABTs can be any of these assets **690** to pay company expenses **610**. Blockchain transactions **600** include bank, cross-border payments, Central Bank Digital Currency (CBDC), Central Bank Digital Asset (CBDA), and crypto liquidity.

Company expenses **610** include payroll **611**, advertisements **612**, equipment **613**, other expenses **614**, travel **615**, loans **616**, banking **617**, space travel **618**, flights **619**, vehicles **620** and education **621**. Company expenses **610** also includes insurance, healthcare, fixed assets, music, video, manufacturing, shipping, education, food including farmed, and lab produced.

Another group of payments is used for lifestyle **630** expenses including flight/travel **631**, rentals **632**, transportation **633**, subscription services **634**, hotels **635**, insurance **636**, healthcare **637**, clothing & accessories **638**, others **639**, furniture **640**, music **641**, restaurants **642**, income **643** and education **621**. Income can also include investment, gifts, universal basic income, allowance, ordinary income, wages, dividend, employee benefits, capital gains, royalties, alimony, unemployment, salary, rent, commission, child support, barter, interest and dividends **644**.

The metaverse **650** is a simulated digital environment that uses augmented reality (AR), virtual reality (VR), and blockchain, along with concepts from social media, to create spaces for rich user interaction mimicking the real world. An additional portion of the APY/APR yield **602** is used for the user wallet **400** of FIG. **4** metaverse **650** expenses including gaming **651**, NFTs **652**, banking **653**, smart contracts **654**, music **655**, video, and education **621**.

The user wallet **400** of FIG. **4** may increase the assets of value **405** of FIG. **4** with investments **660** purchases with a portion of the APY/APR yield **602** for example, stock **661**, cryptocurrency **662**, other investments **663** and education **621**. Other investments **663** include real estate, derivative contracts, machinery, buildings, furniture, education, defense systems, bartering, weapons, transportation, autonomous and regular vehicles, mapping systems, machining including tools and products, internet of things including any device/machine connectable to the internet or device.

Payments on debt **670** are other categories of uses for a portion of the APY/APR yield **602** for example, a crypto loan **671**, student loan **672**, medical loan **673**, car loan **674**, mortgage **675**, and other loans **676**. The user wallet **400** of FIG. **4** may also make at least one charitable donation **680** that benefits with a reduction of income taxes of one embodiment.

FIG. **7** shows for illustrative purposes only an example of an asset management social network platform of one

embodiment. FIG. 7 shows an account owner opening a staked asset account 700 with deposits of assets 710 for example, currency 711, cryptocurrency 642, and assets of value 713 in a blockchain staked account 410 of FIG. 4. Staked value assets 715 can be divided and pledged staked assets 720 with a transfer 721 on the blockchain 722 and deposited in 730 with interest paying and/or servicing entities 731. Interest paying entities 731 pay interest through blockchain 732 activities. Servicing entities receive a portion of earnings from the blockchain of the utilized pledged staked assets they are servicing. Earnings are paid to users and provide users with the APY/APR yield 602.

A user wallet 400 of FIG. 4 deposit a portion of the APY/APR yield 602 into the pledged assets to earn an auto compound yield 455 and pledged staked assets ownership remains with account owner 733. The user wallet 400 of FIG. 4 may issue account owner payment instructions 740 for company expenses 610, lifestyle 620, metaverse 630, ABTs 780, investments 640, debt 650, and charitable donation 660.

The account owner payment instructions are transmitted to an asset management social network platform 750 having a plurality of servers 752, plurality of databases 754, platform computer 756 with a asset management social app 760, and artificial intelligence 770 and/or decentralized applications that run on a Peer 2 Peer (P2P) network of computers communicating with a blockchain network instead of a server and in the case of smart contract networks, also the smart contracts. In another embodiment transactions are made on a P2P network 790 with a P2P cloud 792. The account owner payment instructions are converted onto blockchain transactions. The recorded blockchain transactions provide the account owner with information of the account status and activities of one embodiment.

FIG. 8 shows a block diagram of an overview of a blockchain stake account of one embodiment. FIG. 8 shows the user wallet 400 having a blockchain staked account 410. The user wallet 400 added staked assets including currency 711, cryptocurrency 642, and assets of value 713, ABTs can be any asset of value 808, expenses 800, debts 801, and non-fungible tokens (NFT) 802, derivative contracts 803, escrow accounts 804, treasury, Central Bank Digital Currencies 805 (CBDCs), and Central Bank Digital Assets 806 (CBDA), and tokenized physical assets 807 as Asset Bound Tokens (ABTs) contributing to staked value assets 715. Assets of value 713, derivative contracts 803, and escrow accounts 804 are further described in FIG. 26. The user wallet 400 may pledge a portion of the staked value assets 715 to earn interest. The user wallet 400 can also follow, utilize and/or service staked assets.

The pledged portion of the staked value assets 715 can be placed with entities for a number of types of staked repository blockchain accounts 830. The types of staked repository blockchain accounts 830 include an account owner active participation to earn 840, exchanges non-custodial infrastructure to earn 850 as interest paying entities 731. Other interest paying entities 731 include an individual retirement account (IRA) 860, treasury and traditional investors and asset allocator traditional investment vehicle structure for exposure plus a staking yield 870 of one embodiment.

FIG. 9 shows a block diagram of an overview of metaverse staked value assets transactions of one embodiment. FIG. 9 shows the user wallet 400 that can follow 902 staked value assets 715 and a social credit score 445 ABTs. The staked value assets 715 that earn an APY/APR yield 602 and auto compound yield 455. Followers can subscribe and follow metaverse staked assets and utilize the assets fol-

lowed therefore increasing attention, yield and social credit score for asset owners and creators. Blockchain transfers 900 can be made for metaverse 630 expenses including gaming 631, NFTs 632, banking 633, music 902, characters 903, weapons 904, tools and others 905, ABTs 780, education 621, and avatar 908 with interchangeable characteristics, features, and utility 909. Gaming metaverse 910 includes using an account owner avatar 912. User simulated digital environment interaction 920 includes using augmented reality (AR) 922, blockchain 722, virtual reality (VR) 924, and social media concepts 926. In metaverse the user can use land maps, characters, weapons, tools, etc. including music, transportation maps both physical and digital for direction reinforcement for manual/autonomous transportation, to reduce traffic, check mileage, NFTs (property, cars, and business) on map. Also, emergency alerts, GPS, route quality, accuracy of data, notify department of transportation to repair road/clear hazard.

A user may set up a NFT gallery metaverse 970 to offer for sale avatars 971, virtual land, 972, digital apparel 973, and other items 974. For example, an NFT sale 990 would produce an account owner NFT land sale blockchain transfer 991 and a buyer blockchain cryptocurrency transfer 992 to the user staked value assets 715 account of one embodiment.

FIG. 10 shows a block diagram of an overview of staked value assets investments of one embodiment. FIG. 10 shows the user wallet 400 can follow 902 the staked value assets 715 account. To the staked value assets 715 account is added the APY/APR yield 602, social credit score 445 and auto compound yield 455. The social credit score 445 (SCS) will help to remove spam bots from the systems based on SCS. It will also help remove bad actors from the system. The SCS can also be used to increase/decrease yield. Followers can subscribe and follow staked assets and utilize the assets followed therefore increasing attention, yield, and social credit score for asset owners and creators.

A blockchain transfer to 1000 can be made to purchase investments 640 with the yield new asset to add to the staked value assets 715 account. The investments 640 for example, can include cryptocurrency 642, stock 641 and other investments 643. Types of investments 640 can be appreciating investments that add value to the staked value assets 1010. This may include stock 641 which additionally may pay dividends 1020 paid into the staked value assets 1030 of one embodiment.

FIG. 11 shows a block diagram of an overview of lifestyle expenses of one embodiment. FIG. 11 shows the user wallet 400 can follow 902 staked value assets 715 are APY/APR yield 602, social credit score 445 checked and auto compound yield 455. A blockchain transfer to 1000 can be made to pay lifestyle 620 expenses including flight/travel 1100, rentals 1102, transportation 1104, subscription services 1106, hotels 1108, ABTs 780, and education 621. For example, the user wallet 400 of FIG. 4 can use augmented reality (AR) 922 and virtual reality in metaverse 630 to pay for flight/travel 1100 and hotels 1108 and enjoy virtual and physical sharing of the trip with friends 1110 using the account owner's avatar 912. Followers can subscribe and follow staked assets and utilize the assets followed therefore increasing attention, yield, and social credit score for asset owners and creators of one embodiment.

FIG. 12 shows a block diagram of an overview of blockchain transactions of one embodiment. FIG. 12 shows the user wallet 400 and the user's assets including currency 711, cryptocurrency 642 and assets of value 713. The user wallet 400 can make blockchain transactions to add the assets to the blockchain staked account 410. For example,

the currency **711** can be transferred in a blockchain **#2 1200** transaction. The cryptocurrency **642** in a blockchain **#4 1210** transaction. The additional assets of value **413** transferred in a blockchain **#7 1220** transaction.

The staked value assets **715** added to the blockchain staked account **410** with the three transactions. The blockchain transactions are made in a consecutive chain of transactions and can be identified in a block chain transaction history consisting of blockchain date/time **#1 1230**, blockchain date/time **#2 1240**, blockchain date/time **#3 1250**, blockchain date/time **#4 1260**, blockchain date/time **#5 1270**, blockchain date/time **#6 1280**, and blockchain date/time **#7 1290**. Each immutable blockchain transaction is identifiable with the user public code, date, and time of one embodiment.

FIG. **13** shows for illustrative purposes only an example of account owner blockchain transfers of one embodiment. FIG. **13** shows the APY/APR yield **602** and auto compound yield **455** account owner blockchain transfers **1300**. An account owner NFT land sale cryptocurrency proceeds **1310** is another account owner blockchain transfers **1300** is checked with the social credit score **445** before placed into the staked value assets **715**.

The asset management social network platform **750**, plurality of servers **752**, plurality of databases **754**, platform computer **756**, asset management social app **760**, and artificial intelligence **770**, decentralized application P2P network receive the information of the transfers and update the current status of the user's account. In another embodiment transactions are made on a P2P network **790** with a P2P cloud **792**. The updated current status of the user's account can be reviewed on a user device. The user device **1330** having the asset management social app **760** displays the status and the user checks the account owner staked value assets **715**. This allows the user wallet **400** of FIG. **4** to stay current on the amounts of the currency **711**, cryptocurrency **642**, investments **640** and other assets of value **713** of FIG. **4** in the user's blockchain staked account **410** of FIG. **4**. Current status is transmitted through devices that communicate with other devices using the internet of things, a cell tower, satellites, etc.

The user is also kept current on the APY/APR yield **602** and social credit score **445** to assess the earnings and make any decisions to make a change on the interest paying and/or servicing entities **520** of FIG. **5**. In one embodiment the Asset Bound Tokens (ABTs) values and earnings and the friends associated in the social element activities affecting the social credit score **445** determine the APY/APR yield **602**. Also displayed are a total staked acct. bal. **1340** and yield ytd % **1350**, where acct. bal. means account balance and where ytd means year to date, ABTs **780**, and friends on social network **1351**. The total staked acct. bal. **1340** and yield ytd % **1350** provides financial data to make decisions on selling assets, buying other investments and reappportioning the auto compound yield **455** of FIG. **4** reinvestment of one embodiment.

FIG. **14** shows a block diagram of an overview of a NFT gallery metaverse of one embodiment. FIG. **14** shows a metaverse **630** application of the NFT gallery metaverse **970**. The NFT gallery metaverse **970** in addition to virtual NFT assets is also available to display physical items including real estate properties represented by an NFT **1400**. An account owner can display a real estate properties NFT sale **1410** in the NFT gallery metaverse **970**. Non-fungible tokens (NFT) are a new category of digital tokens, which you can purchase with crypto or fiat currency **1420**. Non-fungible tokens are emerging as vital tools for representing

ownership of physical items on blockchain networks **1430**. The benefits of credible, transparent, and immutable blockchain ownership proof with non-fungible tokens **1440** can facilitate the purchase and sale of physical real estate properties. The immutable blockchain ownership proof with non-fungible tokens can replace volumes of paperwork for purchasing a property conventionally **1450**. Instead of weeks or longer in completing conventional sale and purchase real estate transactions a NFT real estate blockchain transaction can be completed in minutes **1460** of one embodiment. The descriptions continue in FIG. **15**.

FIG. **15** shows a block diagram of an overview of a real estate NFT marketplace of one embodiment. FIG. **15** shows a continuation from FIG. **14** describing a real estate NFT marketplace that provides the assurance of improved security and data integrity **1500**. Using real estate NFTs and yield incentives actions that increase the value and aesthetics of a place including land, communities, cities, neighborhoods, and natural habitats **1502**.

The benefits of blockchain and NFT could provide the confidence buyers, and sellers need for transferring their assets **1510**. Buyers can also find opportunities for borrowing against their real estate NFT with decentralized lending platforms or traditional finance solutions on blockchain **1520** that provide loans to businesses and the public with no intermediaries. On the other hand, decentralized lending platforms lending protocols enable everyone to earn interest on supplied stable coins and crypto currencies in part from interest earned on loans made.

NFTs can be bartered/swapped between users at an equivalent value or price adjustments made to equate value. NFTs can also be rented to other users who want access to play a game with certain characters, weapons, etc.; real estate NFT rental asset etc. rental. Any NFT can be rented to any user; NFTs that represent a physical asset or digital assets.

NFTs can also simplify the process of taking out loans on your property **1530**. NFTs are unique digital assets or tokens for virtual or physical property stored on blockchain networks **1540** of one embodiment. The descriptions continue in FIG. **16**.

FIG. **16** shows a block diagram of an overview of fractional ownership of one embodiment. FIG. **16** shows a continuation from FIG. **15**. Owners of a property's NFT can prove that they own the property **1600** with the credible, transparent, and immutable blockchain ownership proof. Non-fungible tokens in real estate come in two distinct types of tokenization in the use of NFTs for real estate, such as entire asset tokenization and fractional ownership tokenization **1302**. Non-fungible tokens in real estate come in two distinct types of tokenization in the use of NFTs for real estate, such as entire asset tokenization and fractional ownership tokenization **1604**. Fractional ownership (FO) tokenization offers a simple approach to the representation of real estate as NFTs **1602**. Fractional ownership tokenization is a type of crowd funding platform, which helps investors in buying shares in NFT real estate also referred to in real estate as a real estate in investment trust (REIT) **1610**. The fractional owners have a specific number of tokens representing their share in the asset **1620**.

Entire asset (EA) tokenization is a conversion of the actual property deed into an NFT **1630**. The first step of selling real estate in the form of NFTS, the seller needs to fulfill all the mandatory legal prerequisites for ensuring regulatory compliance in blockchain technology and its legal aspect **1640**.

11

The next step is minting an NFT **1650**. The account owner can mint an NFT with a description of the property and legal data associated with the same **1660**. A real estate NFT marketplace offers a safe and flexible environment for creating NFTs **1670** of one embodiment. The descriptions

FIG. **17** shows a block diagram of an overview of selling the property's NFT of one embodiment. FIG. **17** shows a continuation from FIG. **16**. The real estate NFT marketplace helps the account owner incorporate all the necessary paperwork, reports, and disclosures for legal authorities to offer proof of ownership **1700**. The account owner can sell the property's NFT on an NFT marketplace to potential buyers **1710**. Interested buyers would place their bids for the NFT in assets of owner's choice and put into an escrow account **1720**. The winner would pay or swap for the NFT in crypto or fiat currency or asset of owner's choice **1730**. The bids for the NFT would be put into an escrow account to guarantee sell if bidder wins. Once the account owner receives an asset of value, the account owner can initiate a transfer of the NFT to the buyer's wallet **1740**. Buyers would complete the paperwork for finalizing the transfer **1750**. In the end, the buyer gains complete ownership over the property through the non-fungible token representing it **1760** of one embodiment.

FIG. **18** shows a block diagram of an overview of a personal virtual world of one embodiment. FIG. **18** shows the metaverse **330** of the account owner. A metaverse currently is a virtual world created by the users and/or entities **1800**. Metaverse is transitioning to a virtualization focus putting emotion into the code where the digital environments, relationships and activities are perceived as being just as real as their physical counterparts **1810**. The metaverse will include meaningful connections and collaboration experienced in real time where these environments are virtual but the emotions that they evoke are very real **1820**. For example, a user can have shared experiences with other people met in virtual environments and feel as though they have attended something together or have lived something together **1830**. Participating jointly in activities and events in the virtual environments will feel like a real-life experience **1840**. Owning virtual assets with the ability to buy and sell virtual assets will mimic owning physical assets a user can buy and sell **1850**. Accumulation of wealth, digital currencies, taking virtual trips to distance locations, shopping for virtual and physical goods **1860** of one embodiment. The descriptions continue in FIG. **19**.

FIG. **19** shows a block diagram of an overview of attending virtual events of one embodiment. FIG. **19** shows a continuation from FIG. **18**. The metaverse augmented reality provides the user with the ability to attend virtual events with friends, even though the friends may physically be very distant **1900**. Yet virtually the user can sit next to those friends at a concert, hear the music, and look around at other participants **1901**. The virtual experience will feel like physically sharing the same experience with tickets purchased with virtual digital currencies **1902**.

The user can view and purchase brands of goods and services within an augmented reality **3d** virtual environment, able to virtually sit on a sofa and see how it would look in their living room, manipulate tools, view and participate in cooking demonstrations, have verbal discussions with a salesperson face to face virtually, then visit for example, a competing brand to make virtual hands-on comparisons **1910**. The user can collect NFTs represented with a certificate of authenticity for a digital good for owning unique digital assets **1920**. NFTs can include works of art, digital

12

objects and virtual and physical real estate **1930**. NFTs can include unique virtual collectibles and have them digitally signed by a member of the movie cast, band member, athlete or other celebrity **1940** of one embodiment. Descriptions continue in FIG. **20**.

FIG. **20** shows a block diagram of an overview of decentralized, interoperable environment of one embodiment. FIG. **20** shows a continuation from FIG. **19**. The decentralized, interoperable environment of the metaverse will require the creation of open standards that allow for the exchange of information between one platform and system to another **2000**. The user will be able to utilize a digital outfit in a first digital environment and travel to a second digital environment still dressed in the same digital outfit **2010**. Digital environment platforms will allow transferable access between multiple environments on multiple platforms **2020**. Digital gaming can be played in real physical environments on platforms the AR player will move within the real physical environment for example, looking for pirate treasure, walk into a real cave looking for a treasure chest, open the chest and pickup and hold gold coins **2030**. The user will walk into a virtual bank building to a virtual 3d teller, fill-out a withdrawal slip and receive an amount of cryptocurrency then walk out to a virtual vendor and pay for a digital object and each transaction will automatically create a blockchain transaction with the users private code for the withdrawal and public code for the digital object purchase **2040** of one embodiment.

FIG. **21** shows a block diagram of an overview of blockchain staked assets of value escrow accounts of one embodiment. FIG. **21** shows a continuation from FIG. **5** describing blockchain staked assets of value **2100**. Blockchain staked assets of value **2100** include in a continuation from FIG. **8** escrow accounts **804**. Escrow accounts **804** include mortgages **2110**, cross border trades **2111**, freelancer **2112**, indemnity **2113**, online wallet **2114**, software **2115**, cash and document **2116**, inheritance tax **2117**, and derivative **2118**.

Escrow accounts are an arms-length relationship process to hold documentation and funds related to a purchase are held by a neutral third party until both parties to a transaction have performed according to a contract. For example, escrows can be used for real estate sales escrow, mortgage escrow, renter's escrow, and construction escrow of one embodiment.

FIG. **22** shows a block diagram of an overview of blockchain staked assets of value derivative contracts of one embodiment. FIG. **22** shows a continuation from FIG. **8** and FIG. **21** of blockchain staked assets of value **1800**. The blockchain staked assets of value **2300** also shows a continuation from FIG. **5** of the derivative contracts **803**. The derivative contracts **803** include at least one from a group consisting of options **2210**, calls **2211** and puts **2212**. An options contract is an agreement between two parties to facilitate a potential transaction on an underlying security at a preset price, referred to as the strike price, prior to or on the expiration date.

Another group of derivative contracts **803** includes forwards **2220**. Forwards **2220** include window **2221**, long dated **2222**, non-deliverables **2223**, flexible **2224**, closed out rights **2225**, fixed rate **2226**, and options forward **2227**. One example of a forwards contract is an informal agreement traded to buy and sell specified assets, typically currency, at a specified price at a certain future date.

In yet another group of derivative contracts **803** are futures **2230**. Futures **2230** include stock **2231**, index **2232**, commodities **2233**, interest rates **2234**, VIX **2235**, market

13

indexes **2236**, and bonds **2237**. For example, a futures contract is a legal agreement to buy or sell a particular commodity asset, or security at a predetermined price at a specified time in the future. A fourth group of derivative contracts **803** is swaps **2240**. Swaps **2240** include derivatives **2241**, currency **2242**, commodities **2243**, credit default **2244**, interest **2245**, total return **2246**, hybrid exotics **2247**, and data **2248**. In one example a stock swap is the exchange of one equity-based asset for another of one embodiment.

FIG. **23** shows a block diagram of an overview of a blockchain asset management system of one embodiment. FIG. **23** shows a Blockchain Asset Management System (system) is the global system of interconnected networks representing the new internet of value **2300**. The system manages tokenized assets (fungible and non-fungible) between blockchains, networks and devices **2310**. A tokenized asset of this system supports collaboration, communication, and exchange of value between private, public, academic, business, artificial intelligence, and government users and networks that users can read, write, use, and own using smart contracts and other tools **2320**.

Non-Fungible Token assets also known as NFTs characteristically represent a single asset **2330**. When more than one owner wants to own an NFT (single asset) it must be fractionalized **2340**. When an entity wants to increase the value of an existing NFT the entity must create another NFT within that ecosystem in hopes that it will increase the market value for original NFT through brand recognition creating speculative instruments that rely on the “greater-fool theory” from their previous price jumps **2350**. Asset Bound Token (ABT) assets also known as ABTs represent more than one asset (fungible and/or non-fungible) that are combined into a single token **2360** of one embodiment. Descriptions continue in FIG. **24**.

FIG. **24** shows a block diagram of an overview of ABT features of one embodiment. FIG. **24** shows a continuation from FIG. **23**. Each asset within an ABT may have different attributes, characteristics, type, value, or utilities and can be fractionalized or combined by its features and/or each asset within the ABT **2400**. Those assets can be a product, currency, service, specimen, entity, security, and/or anything of value **2410**. An asset creator can increase the value of an ABT by adding additional assets to an Asset Bound Token **2420**. Asset owners within an ecosystem may be able to exchange those individual assets in an asset bound token with each other allowing a user to recompose their owned assets such as art (Not limited to art) **2430**. Some ABTs may expire depending on the asset to reflect wear and tear of product from time of purchase. An expired token can be used to receive a new product. They may also expire to reflect a new product line, and phasing outdated products. Some verified expired products may be reclassified as collectibles. A user who is not a creator, owner, or servicing entity may have limited hold time of an ABT due to lack of staked asset activities on that asset causing their temporary asset to expire.

ABT creators, owners, servicing entities, and/or users receive yield from each transaction when asset is utilized **2440**. Users who receive yield can select to have a portion of their yield donated to offset payments or transaction fees in a favorable manner for users using the asset management social payment tool **2450**. Yield is provided via smart contracts **2460**. Yield can go toward other services, utilities, products or investments (not limited) within the asset management system **2470** of one embodiment. Descriptions continue in FIG. **25**.

14

FIG. **25** shows a block diagram of an overview of asset bound tokens that facilitate market liquidity of one embodiment. FIG. **25** shows a continuation from FIG. **24**. This blockchain asset management system represents the new internet of value and gives all users on the network a unique experience exchanging value and changing the way users of a social network communicate, collaborate, own and share with each other **2500**. Asset Bound Tokens facilitate market liquidity, better price valuations, democratization, increased inclusion, and market participation **2510**.

ABTs gives the opportunity to the average person to purchase high value assets in fractionalized form and swap different features to increase rarity and value and/or change, modify and combine attributes **2520**. An ABT with a low rank and rarity can become a 1 of 1 and/or high rank and rarity if users exchange assets within ABT accordingly **2530**. Different parts of the fractionalized ABT have different rarities and attributes, allowing a user to trade or buy to increase their rarity and value **2540**. (Buy, exchange, swap, and update data, attributes and/or art layers) a verified creator can make an ABT with products from other ABT entities (companies with physical and digital assets and services) on the ABT platform without purchasing them and offer them for sale **2550**. Using smart contracts when those ABTs (group of assets sold as a bundle) are sold then the smart contract will automatically purchase from ABT entities and sent to buyer **2560** of one embodiment.

FIG. **26** shows a block diagram of an overview of asset bound tokens of one embodiment. FIG. **26** shows an Asset Bound Token (ABT) **2600**. A token that represents more than one asset (fungible and/or non-fungible) that are combined into one token **2610**. Each asset within an ABT may have different attributes, characteristics, value, or utilities and can be fractionalized or combined by its features and/or each asset within the ABT **2620**. ABT assets can be a product, currency, service, specimen, entity, and/or anything of value **2630**. ABTs can be bought, sold, created, destroyed, archived, sent, received, converted (vote), rented, donated, shared, followed, unfollowed, and utilized **2640**. ABTs can have more than one owner **2650**. ABTs can have cross platform interoperability **2660**. ABTs can expire as an asset depreciates in value over time or wear and tear **2670** of one embodiment.

FIG. **27** shows a block diagram of an overview of a meal prep ABT of one embodiment. FIG. **27** shows Meal Prep ABT **2700**. A Meal Prep ABT is a single token representing a digital container for a prepared meal with tokenized ingredients (more than one asset) for users to follow, purchase, service, the assets and/or utilize asset benefits **2710**. ABT (Meal 1) **2720** with Chicken NFT, Cauliflower NFT, Broccoli NFT, Salt NFT, Pepper NFT, Fitness Program (cardio) ABT, and Gaming (Speed Attribute .01) ABT. ABT (Meal 2) **2730** with Steak NFT, Rice NFT, Salad NFT, Salt NFT, Pepper NFT, Fitness Program (weight training) NFT, and Gaming (Strength Attribute .01) NFT ABT (Meal 3) **2740** with Salmon NFT, Sweet Potato NFT, Green Beans NFT, Salt NFT, Pepper NFT, Fitness Program (Yoga) ABT, and Gaming (Power Attribute .01) ABT. A Meal Prep ABT has an asset benefit token and different utility within the ABT that gives a single token interoperability that a token creator may provide but not limited **2750**. The Meal Prep ABT is not edible but when staked with a servicing entity the prepared meal is very much edible along with other attributes/characteristics that make ABTs unique and valuable with meal **2760** of one embodiment.

FIG. **28** shows a block diagram of an overview of a meal prep ABT process of one embodiment. FIG. **28** shows Meal

15

Prep ABT Process **2800**. User entity creates ABTs, for example a fitness influencer creates Meal Prep ABTs **2810**. ABTs may be limited to (X amount) ABTs worldwide giving scarcity to this Meal Plan **2820**. ABT creators will receive yield (royalties) from their created assets forever via every transaction **2830**. Users must follow the creator to mint/buy ABT asset **2840**. Consumers purchase Meal Prep ABT **2842**. Now the consumer is ABT owner and will also receive yield from every transaction made with ABT alongside creator until owner sells ABT **2844**.

ABT owner can stake ABT with verified entities to prepare meals for owner and other followers **2850**. (Verified companies will only provide the owner, creator and followers of the owner with this Meal Prep ABT benefits) If a consumer requests to utilize **2852**. The benefits of said ABT the retailer may recommend consumer to own, rent, or follow owner of meal prep ABT **2854**. With every use from consumers the ABT owner(s), ABT creator(s), and verified entities servicing ABT asset will receive yield from each transaction from ABT usage **2856**. Consumer's utilizing asset may receive yield if ABT owner shares that yield from a consumer's transaction **2860** of one embodiment.

FIG. **29** shows a block diagram of an overview of open share of one embodiment. FIG. **29** shows open share is partnering company sells ABT asset to all consumers then ABT creator, owner and servicing entity receives yield from each transaction **2900**. Open share is where a consumer can buy an ABT asset with/without any ABT benefits such as membership for fitness or gaming attributes or unlimited consumer buying opportunities **2910**. ABT owner, creator, and servicing entity still receive yield **2920**.

ABT owners can rent ABTs to consumers including for example gaming, vehicle, home etc. for limited time **2930**. ABT owner can share ABT benefits with their social circle such as followers, friends, family, etc. **2940**. ABT owner can sell ABT and will no longer receive ownership yield from that asset once ownership is transferred **2950**. Users who receive yield can select to have their yield donated to offset payment in a favorable manner for users using asset management social payment tool **2960**. Yield is provided via smart contracts **2970** of one embodiment. Descriptions continue in FIG. **30**.

FIG. **30** shows a block diagram of an overview of verified retail entities of one embodiment. FIG. **30** shows a continuation from FIG. **29**. Yield can go toward other services, utilities, or products within the asset management system **3000**. Verified retail/servicing entities can link to ABT asset or follow ABT owner to provide asset benefits to asset followers and the transaction will provide yield via smart contract to retailer, owner and creator **3010**. ABTs are limited and unique generating scarcity **3020**. This is why ABTs are a valuable asset to own **3022**. Followers will be able to utilize the benefits of an asset bound token of whom they are following **3030**. The ABT creator and owners and servicing entities will be able to receive yield for providing benefits to followers with the option to share yield with followers **3040**.

When a user follows ABT owner/asset they will automatically follow ABT creator **3050**. When an ABT buyer purchases an asset, it will recommend to users who are interested if they want to follow the new ABT owner(s) **3052**. When an ABT owner sells an asset, followers who utilize that asset will have the option to follow new owner(s) of the asset **3054**. ABT owners may not want to lose their followers so they may hold asset until indefinitely or when the value of asset has increased. ABT creators will have the "option" to give their ABTs additional scarcity by limiting

16

followers of an asset **3060**. Only so many followers can follow an ABT asset (depending on asset type) to allow that asset to distribute economic balance within its ecosystem of assets **3062**. When that ABT ecosystem is maxed out with followers then additional spaces for followers and/or additional ABTs will be introduced to the ecosystem **3064** of one embodiment.

FIG. **31** shows a block diagram of an overview of Interoperability of one embodiment. FIG. **31** shows Interoperability **3100**. ABTs can have cross platform interoperability **3110**. Every time an asset is used for a transaction it can give your game character in game attributes such as strength, speed, power, etc. **3120**. A Supranational Asset, a corporation and its assets can become an ABT **3130**. A multi asset payment system with federated side chains can be used **3140**. Geographic yield for sharing location and/or being in a place or event **3150** of one embodiment.

FIG. **32** shows a block diagram of an overview of a social credit score of one embodiment. FIG. **32** shows the goal of a social credit score is to prevent spam and maintain a standard within the asset management system **3200**. Creator-Does not Spam users **3210**. Verified Company, etc. Owner-Does not spam users, utilizes asset in ecosystem **3220**. A buyer/user Participates in owner vote and participate in ecosystem, etc. **3230**. Buyer utilizing assets in other ecosystems **3232**. A buyer owns any other assets, etc. **3234**. A user utilizes assets from whom they are following, and unlimited others **3236**.

A verified company or verified entity that meets the qualifications to service an asset **3240**. Incentive for users to also share their decentralized identifier data to receive yield from entities **3250**. When user stops sharing their data with an entity, they stop receiving yield from said entity of use **3260** of one embodiment.

FIG. **33** shows a block diagram of an overview of an algorithmic asset bound token of one embodiment. FIG. **33** shows an Algorithmic Asset Bound Token (AABT) **3300**. An algorithmic token that can fractionalize fungible assets and make fungible assets whole to stabilizing asset value **3310**. The algorithm will automatically merge, fractionalize, wrap, create and destroy assets to stabilize an assets value **3320**. If the price becomes too high, then assets will fractionalize and/or create more assets and if the price becomes too low then assets will be merged and/or destroyed to increase asset value **3330** of one embodiment.

FIG. **34** shows a block diagram of an overview of ABT market security of one embodiment. FIG. **34** shows ABT market security is maintained for any addresses that create a large buy/sell order of fungible assets; those assets will automatically combine and become ABTs to decrease market manipulation and liquidity and/or be bought/sold Over-The-Counter (OTC) as an ABT **3400**. ABTs can be fractionalized and sold in low volumes **3410**. If unusual amounts of sell/buy orders from similar accounts attempt to buy fungible assets at one time to create an artificial pump/dump the assets can group together to become a basket of assets to decrease liquidity flow **3420**.

In one example, opposite of the way stock splits work to increase liquidity this system will be able to merge assets to decrease liquidity and laterally split assets **3430**. Another example is the way fruit is bought at the store **3440**. You can buy a diced pineapple, half a pineapple, a whole pineapple, or a bunch of pineapples **3442**. Those options would still be available but in smaller quantity **3444**. Reward network participants with a token so the network is fault tolerant, attack resistant and collusion resistant give user option to make ABT whole or fractionalized if whale is dumping on

the market **3450**. Decentralized security setting can be real-time or automated via user choice **3460**. If automated, then reward tokens to users participating with securing the network **3470**. If manual, then fewer tokens rewarded but will receive when option is chosen to protect the network **3472**. Also using decentralized Identifier **3474** of one embodiment.

FIG. **35** shows a block diagram of an overview of decentralized identifier data of one embodiment. FIG. **35** shows Decentralized Identifier Data (DID) **3500**. (DID) tokens can be used to prevent spam by holding customer's data such as staked asset activities as a means to verify if the user is a real person or bot **3510**. ABT can be used as verified asset like a blue checkmark for the social ABT system **3520** of one embodiment.

FIG. **36** shows a block diagram of an overview of an ABT land example of one embodiment. FIG. **36** shows an ABT land example **3600**. The land is a parcel with a house and a farm **3610**. Farming/lab grown foods yield that increases value by production of crops, edible proteins, and nutritional foods/drinks to the ecosystem generates yield to produce more nutritional foods and or purchase other farmed foods **3612**. The healthiest most sustainable foods, ingredients, and methods used by entities are incentivized with yield **3614**.

That whole asset can be fractionalized, and each fraction has different values and attributes the listing can be sold as whole or different pieces can be purchased **3620**. The listing can show the whole asset sale price with a breakdown of the fractionalized assets within a single ABT whether listed separately for sale or not to show complete asset value **3630** of one embodiment.

FIG. **37** shows a block diagram of an overview of data for education of one embodiment. FIG. **37** shows old data for education is challenged and revalidated/tested by multiple entities to update outdated education data and systems to create a universal education system **3700**. When old data is swapped with new data users of the new data will receive yield **3710**. There can be no conflict of interest **3712**. Entities will be paid for data **3720**. Any data that has value can be swapped, exchanged, validated, and used **3730**. Yield can be received by entities by staking valuable data for users and other entities **3740** of one embodiment.

FIG. **38** shows a block diagram of an overview of smart contracts of one embodiment. FIG. **38** shows smart contracts **3800**. Smart contracts **3800** incorporate features including self-verifying **3810**, self-executing **3820**, tamper resistant **3830**, higher transparency **3840**, fewer intermediaries **3850**, lower transaction costs **3860**, and automated legal obligations processes **3870** of one embodiment.

FIG. **39** shows a block diagram of an overview of web 3 applications of one embodiment. FIG. **39** shows web 3 applications run on a combination of networks performing backend operations **3900**. A distributed ledger serves as the backbone for other web 3 networks collectively managed and incentivized by a token **3910**. Security is provided by a P2P network validating transactions by majority consensus **3920**. A web 3 example of selling and buying a car where User1 leaves a car and car key in a garage locked with a smart contract controlled with a smart lock **3930**. The car has a unique blockchain address registered on a ledger **3940**.

The smart lock verifies to the blockchain network ledger that the car is parked in the garage **3942**. The User1 terms to sell the car are defined in the smart contract **3944**. User2 wants to buy the car **3950**. User2 signs the smart contract and transfers the purchase price via the User2 key to the User1 blockchain address **3952**. The blockchain network

confirms the transaction and provides User2 with the access code to the smart lock **3954** of one embodiment.

FIG. **40** shows a block diagram of an overview of a global supply chain of one embodiment. FIG. **40** shows a global supply chain is created if multiple assets are shipped from different manufacturers from country A to ship to country B to supply buyers **4000**. Global supply chain assets would be separate ABTs with multiple transactions until they are loaded onto a transport mode, for example a ship, train, or plane **4010**. When on the transport mode these assets could be bundled together to keep shipping transaction costs low **4020**. Upon arriving in country B, the assets would fractionalize according to its buyers and destinations **4030**.

If for example 30 assets are going to one buyer, then those 30 assets would merge into 1 ABT (Meta data intact) and move across the blockchain **4040**. If those 30 assets were going to one buyer and 8 locations, then the ABTs would fractionalize accordingly to those 8 locations as 8 ABTs **4050**. Also, an individual buyer can have their single asset co-packaged with a bulk shipment from a bulk buyer to reduce the cost for a single shipment of the individual asset. For example, if 100 bulk assets were packaged for shipping from somewhere (such as an overseas shipment) for a bulk buyer, a single asset from individual buyers could be co-packaged with the 100 assets. This arrangement would lower the shipping costs for the individual buyers of their respective single assets while decreasing the total costs for bulk buyer of 100 assets. Merging and fractionalizing assets can be used to increase transaction speed and reduce fees across the blockchain **4060**. This also removes the bottleneck of too many transactions per second **4070**. Some transactions can hold payments and products for a limited time (delayed gratification feature) until all products have been selected and depends on the social credit score or relationship with entity **4080**. The payment will lock, the product will lock guaranteed sale has been made, and locks price **4090** of one embodiment. Descriptions continue in FIG. **41**.

FIG. **41** shows a block diagram of an overview of transaction fees of one embodiment. FIG. **41** shows a continuation from FIG. **40**. If funds are not available, then a transaction or product will not be put into cart **4100**. If going to the same warehouse A then products will merge or continue to stay merged until arrival at warehouse A and then fractionalize (unless arriving at same destination) to make it to its final destination **4110**. Transaction and/or shipping fees can be split between users if users want to temporarily merge (piggyback or transaction batching) their ABTs with others to decrease transaction or shipping costs **4120**. Temporary mergers require a new identifier with Meta data and a smart contract to go to correct user's wallet **4130** or shipping address. This enables the network to increase transaction throughput and helps to increase scalability **4140**.

ABT assets are interchangeable and interoperable with interdependent layers **4150**. A basket of currencies, stocks, derivatives, etc. can operate on permissioned and permission less networks **4160**. When buying ABT art or any other ABT asset the buyer must buy with the first layer ABT token whether the asset is bound to one asset or a basket of assets **4170**. A user can sign a transaction to automate the user's wallets within an ABT to create a smart wallet **4180**. These users (entities) can be contractors, buyers, sellers, governments, banks, and unlimited types of users (entities) **4182**. They can rent out (loan) this ABT or sell it **4184** of one embodiment. Descriptions continue in FIG. **42**.

FIG. **42** shows a block diagram of an overview of ABT creators of one embodiment. FIG. **42** shows a continuation

from FIG. 41. Since ABTs are interchangeable and interoperable many small businesses have an opportunity to partner with ABT creators to package an ABT for the market and all assets within an ABT are interchangeable 4200. Verified small businesses can partner together to make an ABT collection of assets and combine products into one asset using an e-commerce platform that runs on the ABT blockchain 4210. Giving small business owners a chance to participate in the blockchain 4220.

ABTs could also be used to track productivity 4230. You can buy ABT books and lend them to a friend and the book will automatically be returned to the owner 4232. The ABT book can let the owner know how far along a friend user is in the ABT book to extend lending time 4234. ABT owners can donate their assets at any time including physical products 4240.

Hotels can have rooms for rent using ABTs and package each room with what is available into one ABT including cleaning service 4242. Once the room is cleaned the cleaning service can sign to have the room moved to the new renter 4250. The pre-rented ABT will automatically move to the renter's wallet letting them know the room is available for a limited rental time 4260. Although check-in time may be 3 PM the room may be finished and available at 1 μm 4270 of one embodiment.

FIG. 43 shows a block diagram of an overview of an ABT customer data platform of one embodiment. FIG. 43 shows an ABT customer data platform for collecting information on how users purchase ABTs to market their interest to users 4300. If a user shares data with the ABT customer data platform, then user can receive yield from an ABT social platform 4310. Attention, products and services are the currency of entities 4320 of one embodiment.

FIG. 44 shows a block diagram of an overview of data modeling of one embodiment. FIG. 44 shows the database system employs a well-structured data model, comprising four fundamental components that collectively manage and interlink data seamlessly. Token holder records form an integral part of the data model. each token holder record is uniquely identified by a token holder connect key and/or token holder connect id. these identifiers play a crucial role in the precise identification and management of individual token holders within the system.

The database system includes data modeling 4400 that provides a token holder connect 4410 to all token holders 4412. The data modeling 4400 stores token holder data 4414. The database system efficiently manages digital tokens known as Asset Bound Tokens (ABTs). These tokens represent a wide array of assets, including securities, derivatives, commodities, and other fungible and non-fungible instruments. The data modeling 4400 records asset groups 4416 of the ABTs in a transaction studio 4420.

The information is recorded in token attribute/wallet repositories 4422 that include non-sendable 4424 and sendable 4426 information and data. Linkage Between Repositories allows in specific scenarios where a sendable repository communicates with an asset holder, the Repository Key can also function as an Asset Holder Key. Consequently, the Asset Holder Key becomes equivalent to the Token Holder Connect ID. This linkage ensures that the asset holder's information is appropriately connected to the token data, enabling smooth and secure transaction processing. The asset holder controls a login for the database system 100 of FIG. 1 to send relationship repository key becomes asset holder key 4428 allowing the asset holder to track and monitor transaction records 4430, compliance metrics 4432, and observe tracking 4434 of the transactions.

A profile and preference center 4436 stores an asset holder list 4440 and asset groups 4442. Transaction categories 4444 include automated compliance auditors 4446. The automated compliance auditors 4446 check public compliance records 4452 for any restricted transactions 4454 not in compliance with regulatory authorities 4450 mutually agreed restrictions 4464.

Restricted Transactions pertain to transactions that are subject to specific limitations or restrictions imposed by regulatory authorities or compliance auditors. These restrictions enhance transparency by clearly defining the constraints and obligations associated with a transaction. All parties are aware of and consent to the limitations, reducing the risk of disputes or misunderstandings. Transaction attribute filters 4460 in an assetflow journey builder 4462 identify any detected restricted transactions 4454 of one embodiment.

FIG. 45 shows a block diagram of an overview of transaction studio of one embodiment. FIG. 45 shows import data 4500 for storing in a transaction studio 4510 to create a token holder connect 4520. An assetflow automation suite 4530 includes a setup menu 4540, manual import 4550, import file activity 4560, and API 4570. The application programming interface (API) is used to connect multiple computers to communicate data between them. The assetflow automation suite 4530 is configured to cater to the specific requirements of large entities engaged in the utility of asset bound tokens (ABTs) and the management of digital assets and financial instruments. The assetflow automation suite 4530 provides a comprehensive set of automation tools:

1. Scheduled Workflows: Configure scheduled workflows to automate routine tasks like data imports, token issuance, or compliance checks. Ensure precise data management and timely operations by scheduling workflows at predefined intervals.

2. File Integration Automations: Deploy File Integration Automations to seamlessly receive and process external data files. This feature streamlines data imports when a file is dropped, making it efficient, even when dealing with substantial transaction volumes or asset updates.

3. Event Driven Automations: Set up Event Driven Automations to respond swiftly to specific occurrences within the database. For instance, when a user initiates a token transfer or requests compliance verification, Event Driven Automations execute the necessary actions automatically.

4. SQL Data Query: Harness SQL Data Query such as action query, a select query, or a combination of both to retrieve and segment data within the database. This functionality is particularly valuable for creating targeted asset or user groups based on attributes like asset ownership, compliance status, or transaction history.

5. Data Integration Automations: Automate the importing process of Asset Groups or Repositories with external files using the Data Integration Automations. This feature facilitates the efficient management of user data and asset information, ensuring the database remains current.

6. Custom Workflow: Create customized Workflows to execute intricate operations within the database. These tailored workflows align with specific business rules and requirements, providing flexibility and precision.

7. Data Filtering: Implement Data Filtering to refine and segment data based on predefined criteria. This capability proves beneficial when you need to isolate specific attributes or assets for targeted actions.

8. Data Extraction: Automate data extraction from the database using Data Extraction. This functionality generates

reports, compliance documentation, or data backups, ensuring crucial information is readily accessible.

9. Workflow Orchestration: Strategically introduce delays in the automated processes with Workflow Orchestration. For example, you can include wait periods for compliance verifications or to synchronize asset updates.

10. Workflow Control: Retain complete control over running workflows by pausing, skipping, or stopping them as required with Workflow Control. This flexibility enables efficient operations and real-time adjustments.

11. Workflow Duplication and Management: Empower administrators to duplicate and customize workflows to address various scenarios effectively. Additionally, provide the option to manage and remove workflows that are no longer relevant, ensuring a streamlined interface.

12. Workflow Monitoring and Performance: Implement tools to monitor workflow history and performance. Keep tabs on successful runs, error tracking, and performance metrics, enabling continuous optimization of the automated processes.

13. Transaction Management: Assetflow Automation Suite incorporates Transaction Management features from Transaction Studio to automate various financial processes. For example, automated routines can be configured to initiate buy or sell transactions based on predefined criteria, such as specific asset performance metrics or market conditions. This streamlines asset management processes and reduces manual intervention.

14. Transaction Approval Workflow: The Assetflow Automation Suite integrates seamlessly with the Transaction Approval within Transaction Studio. Automated routines can be designed to follow approval processes when necessary. If a transaction meets specific criteria that require approval, the automation triggers the workflow, and Administrators can review and approve transactions through the suite.

15. Transaction Notifications: Assetflow Automation Suite provides notification capabilities to alert users about automated transaction activities. When an automated transaction is executed or requires attention, notifications are sent to designated users, ensuring they are informed and can take appropriate actions.

16. Reports: Empowers users to track and analyze the performance of their marketing

campaigns and customer journeys. The suite offers robust reporting capabilities that provide valuable insights into customer behavior, campaign effectiveness, and journey outcomes, including transactions and transfers of ABTs and other digital assets.

FIG. 46 shows a block diagram of an overview of segmenting data of one embodiment. FIG. 46 shows segmenting data 4600 using filtered repositories 4610, data filters 4620, and SQL queries 4630 using an audience segmentation manager 4640. The database for asset bound tokens system is not only to manage ABTs comprehensively but also serves as a powerful platform for processing and facilitating a wide range of transactions involving these digital tokens. It incorporates precise identification, efficient data management, and secure linkage mechanisms to ensure the smooth operation of the financial ecosystem it supports.

The Wallet Repositories are categorized into different types, such as Standard, Filtered, or Random, depending on their intended usage. These Wallet Repositories can be designated as Sendable or Non-Sendable. Standard Wallet Repositories are used for typical wallet management and storage of Wallet related data. They serve as the default storage for wallet information and are suitable for most use

cases. Filtered Wallet Repositories are used to create subsets or segments of wallet data from existing repositories. They allow the administrator to define specific criteria or filters to select a subset of wallet records. This type is useful when the administrator needs to work with a specific group of wallets within the system. Random Wallet Repositories enable the administrator to randomly select wallets from a source repository. This can be beneficial when the administrator needs to perform random sampling or select wallets for specific purposes.

The Token Attribute Repositories (TARs) are pivotal components of the system, facilitating granular compliance enforcement and transaction tracking. TARs enable one-to-one, one-to-many, and many-to-many relationships between ABTs and underlying assets. They store attribute-based transaction histories, allowing for a comprehensive view of compliance adherence. The database system also provides robust data integration capabilities, enabling data import and export via secure SFTP connections. Data can be encrypted or decrypted as needed to protect sensitive information, particularly wallet keys and transaction records. For optimal performance and scalability, the system adheres to data management guidelines. These guidelines recommend limiting the number of fields and characters within Wallet Repositories to ensure efficient data storage and retrieval. This design approach ensures that the system can accommodate a high volume of ABTs, supporting the needs of corporations, governments, holding companies, and other entities. In this case they will be known as administrators. Furthermore, the system is designed to facilitate user hierarchies, enabling companies and governments to gain insights into how customers utilize their assets.

FIG. 47 shows a block diagram of an overview of wallet messages of one embodiment. FIG. 47 shows a build messages 4700 feature of the database system server 100 of FIG. 1. The build messages 4700 feature creates notification messages 4710 sent to wallet owners directly and through other communication channels 4720. The build messages 4700 feature includes wallet messages 4730, asset personalization tags 4740, dynamic content 4750, use of message templates 4760, and content blocks 4770 of one embodiment.

Message building creates messages for communication with wallets in the database involving various elements, including Asset Personalization Tag, Dynamic Content, Message Templates, Content Blocks, and AssetScript (scripting capabilities). These features are further described as follows:

1. Asset Personalization Tags: asset personalization tags are personalized strings that allow you to insert dynamic information into the messages. These tags act as placeholders that get replaced with specific wallet-related data when the message is sent. For example, you can use an Asset Personalization Tag like %WalletBalance%% to personalize messages with the recipient's current wallet balance.

2. Dynamic Content: Dynamic Content are dynamic content elements that enable you to create message variations that are automatically selected based on specific conditions or recipient attributes. For instance, you can use Dynamic Content to display different content to wallet holders based on their asset type, transaction history, or compliance status.

3. Message Templates: Message Templates are pre-designed message layouts tailored for wallet-related communication. These templates provide a consistent and visually appealing format for the messages. A user can choose from a library of Message Templates or create custom ones to suit

various communication needs, such as transaction notifications, compliance updates, or asset statements.

4. Content Blocks: Content Blocks are modular components that you can use to assemble the messages. These blocks can contain text, images, links, and other content elements. When building a message, a user can arrange Content Blocks to create a message structure that conveys information effectively to wallet holders.

Testing content within this database, particularly for communication purposes, involves ensuring that messages sent to wallet holders are accurate, compliant with regulations, and successfully connect to the intended wallet addresses. Testing content operates as follows:

1. Token Holder Preview: Before sending any messages to wallet holders, administrators have the option to utilize a “Token Holder Preview” feature within the database. Token Holder Preview allows administrators to review how the message content will appear to wallet holders before it is sent. This ensures that the message is formatted correctly, and any personalized information, such as token balances or transaction details, is accurate. Administrators can select specific wallet holders or groups to preview the message and verify that the content is tailored appropriately to the recipients.

2. Message Compliance (CAN-SPAM and GDPR Regulations): Compliance checks within the database now encompass both CAN-SPAM and GDPR regulations. Before sending any messages to wallet holders, administrators can run compliance checks on their message content to ensure it adheres to these regulations. The database verifies that messages include essential elements required by both regulations, such as an opt-out mechanism, a valid physical address, accurate sender identification, and explicit consent for data processing when applicable. Administrators receive guidance and recommendations to maintain compliance with both CAN-SPAM and GDPR when creating message content.

3. Connects to Wallet Address: To test whether a message successfully connects to the intended wallet address, administrators can use a “Connectivity Test” feature. This feature allows administrators to simulate the message delivery process. Administrators can select specific wallet addresses or groups and send test messages. The database monitors the delivery process and provides real-time feedback on whether the message was successfully delivered to the wallet address or if any issues occurred.

4. Message Personalization and Dynamic Content: Testing content also involves verifying that dynamic content and personalization are functioning correctly within the messages. Administrators can use placeholders and dynamic content tags in their message templates. During testing, the database ensures that these placeholders are replaced with the accurate and up-to-date information for each wallet holder. Administrators can preview how dynamic content will appear for specific wallet holders to confirm that personalization is working as intended.

5. Testing Variations: Administrators have the flexibility to test different variations of message content. For instance, they can create A/B tests to assess which message content or format performs better in terms of engagement or compliance. The database tracks the performance of these variations and provides insights into which content resonates most with wallet holders.

6. Delivery and Read Receipts: As part of the testing process, the database tracks delivery and read receipts. Administrators can monitor whether wallet holders have received and opened the messages. This information is

valuable for assessing the effectiveness of communication and making necessary adjustments to message content. Testing content within this database for communication involves a multifaceted approach.

Administrators can preview message content, ensure compliance with regulations like CAN-SPAM, verify successful delivery to wallet addresses, test dynamic content and personalization, and assess message variations. By conducting comprehensive testing, administrators can optimize their communication strategies, maintain compliance, and deliver accurate and engaging messages to wallet holders.

Sendable vs. Non-Sendable Wallet Repositories: The designation of a Wallet Repository as Sendable or Non-Sendable pertains to its relationship with communication channels and the ability to send messages or notifications to the wallet owners. Each designation means the following: Sendable Wallet Repositories: Sendable Wallet Repositories are those that have a send relationship with communication channels.

In the context of this system, this means that wallet owners associated with sendable wallet repositories can receive messages or notifications through various communication channels, such as email, SMS, or other methods. These repositories are typically used for engaging with wallet owners and facilitating communication.

Non-Sendable Wallet Repositories: Non-Sendable Wallet Repositories, on the other hand, do not have a direct send relationship with communication channels. Non-Sendable Wallet Repositories are used for reference and data storage purposes but are not intended for sending messages or notifications to wallet owners. Non-Sendable Wallet Repositories may contain important wallet-related information, but they are not actively used for communication.

The categorization of Wallet Repositories into standard, filtered, or random types allows the administrator to organize and manage wallet data efficiently based on different use cases and requirements. Additionally, the designation as Sendable or Non-Sendable determines whether the wallet data in a particular repository can be used for communication purposes or if it is strictly for data reference and storage. This flexibility ensures that the system can adapt to a wide range of scenarios and administrator needs while maintaining clarity in data management.

1. Sendable Wallet Repositories: Using Sendable Wallet Repositories for communication with wallet owners is a practical way to facilitate two-way communication. This allows the administrator to send transaction notifications, important updates, or other relevant information directly to wallet users. It’s important to ensure that communication through Sendable Wallet Repositories is secure and complies with privacy regulations, as cryptocurrency-related communications involve sensitive data.

2. Non-Sendable Wallet Repositories: Designating certain Wallet Repositories as Non-Sendable for storing data not intended for direct communication but essential for wallet management and analytics is a good practice. This clear separation between data used for communication and internal data can help maintain data integrity and streamline the database.

3. Data Retention: Implementing data retention policies within Wallet Repositories is crucial, especially for regulatory compliance. Ensuring that transaction history and related data are retained for the required period while adhering to data protection regulations is essential. This ensures that the administrator maintains a compliant and well-managed database.

4. Data Storage and Scalability: Storing data in an external SFTP storehouse and only calling data into the database when needed for analytics is a sound approach for scalability. It minimizes the storage burden on the primary database and allows the administrator to manage large volumes of data efficiently. This balances the need for communication, data management, and scalability. To ensure a robust and scalable system.

FIG. 48 shows a block diagram of an overview of file integrations automations of one embodiment. FIG. 48 shows an assetflow automation suite 4800 including starting sources 4810 for the file integrations automations 4812. File integrations automations 4812 include scheduled workflows 4814, automation tools 4820, verification 4830, and SQL data query 4831. File integration automations 4832 also include data integration automations 4833, data filtering 4834, send message 4835, and data extraction 4836. File integrations automations 4812 uses include workflow control 4840, workflow orchestration 4841, reports 4842, refresh filtered list 4843, workflow duplication and management 4844, and send wallet message 4845 of one embodiment.

FIG. 49 shows a block diagram of an overview of assetflow journey builder of one embodiment. FIG. 49 shows an assetflow journey builder 4900 that shows starting sources 4910 for the repository 4920. An API event 4921 and in app engagement 4922 are displayed for an audience 4923 for a particular event 4924. A wallet message engagement 4925 is shown for a wallet app event 4926. Activities 4930 are notified with message activities 4932 involving a wallet 4934 and a token 4936.

Journey builder activities 4940 include wait activities 4950, wait by duration 4951, wait by attribute 4952, wait until event 4953, wait until in-appengagement 4954, wait until date 4955, and wait response 4956. Activities may include split activities 4960, frequency split 4962, decision split 4964, wait until push engagement 4966, and wait until in-appengagement 4968. The wallet holder may elect to join 4970 the activities of one embodiment.

AssetFlow Journey Builder in this database system revolutionizes how large corporations manage and transact Asset Bound Tokens (ABTs) and other financial instruments while overseeing digital wallets. AssetFlow Journey Builder is a robust toolset designed to meet the unique needs of financial institutions, empowering them to create highly customizable journeys.

The assetflow journey builder includes the following: 1. Customized Journey Templates: Create highly personalized journey templates specifically designed for financial scenarios. These templates encompass "ABT Issuance Journey", "Asset Portfolio Management Journey," and "Investor Onboarding Journey," among others. These templates streamline complex processes, providing a seamless experience for both issuers and investors.

2. Audience Segmentation: Harness the "Create an Audience from Token Holders" feature to segment database users based on intricate criteria, such as asset class, investor type, or geographic region. Precise audience segmentation ensures that communications and actions within journeys are precisely targeted. Audience Segmentation allows marketers and business users to create customer journeys and campaigns. When defining these journeys, they can specify target audiences based on asset categories and attributes defined in Asset Groups. For example, a campaign could target customers holding specific types of digital assets within predefined Asset Groups.

3. Event-Driven Journeys: Use events strategically to trigger journeys based on critical user actions and system events. For instance, when a corporation issues new ABTs or a high-value transaction is executed, AssetFlow Journey Builder initiates journeys, incorporating compliance checks, real-time notifications, and portfolio adjustments.

4. Goal-Oriented Journeys: Define specific objectives for each journey, such as capital raising, asset diversification, or regulatory compliance. These goals provide a clear roadmap for journey success and enable precise measurement of outcomes.

5. Activities for Financial Workflows: Customize journeys with financial-centric activities like "Capital Injection Verification," "Asset Valuation," and "Regulatory Compliance Audit." These activities facilitate intricate financial processes within each journey.

6. Strategic Wait Activities: Implement wait activities strategically within journeys to introduce calculated pauses. For instance, waiting periods for compliance approvals or scheduled asset revaluation ensure that each step is executed with precision.

7. Intelligent Decision Splits and Joins: Employ decision splits and join activities to dynamically route users based on their financial profile, risk appetite, or investment strategy. Personalization is at the core of AssetFlow Journey Builder, ensuring that each investor receives a tailored experience.

8. Data-Driven Insights: Leverage the power of Journey Analytics and the Versions Dashboard to gain insights into journey performance. Metrics like capital raised, risk exposure, and investor satisfaction are meticulously tracked, allowing for data-driven optimization.

9. Validation for Reliability: Prior to launching a journey, utilize the validation feature to ensure all components, activities, and event-driven function as intended. This meticulous validation process guarantees a seamless and error-free administrator experience.

10. Organized Journey Repository: As the financial database grows, maintain a well-organized journey repository. Categorize journeys into sections such as "Capital Raising Journeys" and "Asset Management Journeys" to simplify administrator navigation.

11. Efficient Duplication and Deletion: AssetFlow Journey Builder facilitates the duplication and deletion of journeys. Corporations can effortlessly create customized variations of existing journeys while keeping their journey library clutter-free.

12. Portfolio Management Integration: Assetflow Journey Builder integrates with the portfolio management capabilities of Transaction Studio. Marketers can create customer segments within Journey Builder based on portfolio performance metrics. This allows for highly targeted marketing efforts, such as offering promotions to customers with portfolios showing specific investment patterns.

AssetFlow Journey Builder empowers financial institutions, governments, and corporations to create dynamic, user-centric journeys, whether they are focused on managing ABTs, transacting financial instruments, or ensuring regulatory compliance. This toolset is designed to the specific needs of large entities, you can streamline complex financial processes, enhance user engagement, and drive success in the world of digital finance of one embodiment.

FIG. 50 shows a block diagram of an overview of data insights of one embodiment. FIG. 50 shows reporting 5000 that includes reports 5010, data insights 5020, and processes to send logs 5030 to wallet owners. Reporting and analytics tools are available, allowing administrators to generate custom reports and dashboards tailored to their specific require-

ments. In addition to scalability and performance considerations, the system places a strong emphasis on compliance and auditing. KYC procedures are in place to verify wallet owners, ensuring adherence to regulatory requirements.

This financial system and database architecture introduces a unique approach to managing digital Asset Bound Tokens (ABTs) that represent multiple assets. It provides a comprehensive and secure solution for asset management, transaction tracking, and regulatory compliance in the digital asset space of one embodiment.

The database system is configured to efficiently manage digital tokens known as Asset Bound Tokens (ABTs). These tokens represent a wide array of assets, including securities, derivatives, commodities, and other fungible and non-fungible instruments. The database prioritizes data security, scalability, and regulatory compliance while also serving as a robust platform for processing and facilitating transactions. The database system employs a well-structured data model, comprising four fundamental components that collectively manage and interlink data seamlessly. The four fundamental components include 1. Token Holder Records, 2. Wallet Repositories, 3. Token Attribute Repositories, and 4. Asset Management Modules.

1. Token Holder Records: Token Holder Records form an integral part of the data model. Each Token Holder Record is uniquely identified by a Token Holder Connect Key and/or Token Holder Connect ID. These identifiers play a crucial role in the precise identification and management of individual token holders within the system.

2. Wallet Repositories: Wallet Repositories utilize a distinct identification method, known as the Wallet Repository Key and/or Wallet ID. These identifiers are essential for accurate tracking and efficient management of wallet-related data, including transactions and holdings.

3. Token Attribute Repositories: Token Attribute Repositories are designed to organize and access attributes associated with tokens. They are identified using a unique Token Attribute Repository Key and/or Token Attribute Repository ID, enabling structured management of token-related data.

4. Asset Management Modules: The database includes Asset Management Modules, which are responsible for efficiently managing various assets represented by ABTs. These modules interact seamlessly with the other components to facilitate transactions and asset-related activities.

Linkage between repositories allows in specific scenarios where a sendable repository communicates with an asset holder, the Repository Key can also function as an Asset Holder Key. Consequently, the Asset Holder Key becomes equivalent to the Token Holder Connect ID. This linkage ensures that the asset holder's information is appropriately connected to the token data, enabling smooth and secure transaction processing.

Data organization and connectivity the data structure creates a well-organized and interconnected system for managing data within the database. Each component maintains its unique identifiers, ensuring precise identification and efficient data management. Furthermore, this architecture allows for seamless linking between asset holders and tokens, facilitating secure and transparent transaction processing within the database. The database system is not only configured to manage ABTs comprehensively but also serves as a powerful platform for processing and facilitating a wide range of transactions involving these digital tokens. It incorporates precise identification, efficient data management, and secure linkage mechanisms to ensure the smooth operation of the financial ecosystem it supports.

The Wallet Repositories are categorized into different types, such as Standard, Filtered, or Random, depending on their intended usage. These Wallet Repositories can be designated as Sendable or Non-Sendable.

The Token Attribute Repositories (TARs) are pivotal components of the system, facilitating granular compliance enforcement and transaction tracking. TARs enable one-to-one, one-to-many, and many-to-many relationships between ABTs and underlying assets. They store attribute-based transaction histories, allowing for a comprehensive view of compliance adherence.

The system also provides robust data integration capabilities, enabling data import and export via secure SFTP connections. Data can be encrypted or decrypted as needed to protect sensitive information, particularly wallet keys and transaction records. For optimal performance and scalability, the system adheres to data management guidelines. These guidelines recommend limiting the number of fields and characters within Wallet Repositories to ensure efficient data storage and retrieval. This configuration ensures that the system can accommodate a high volume of ABTs, supporting the needs of corporations, governments, holding companies, and other entities. In this case they will be known as administrators.

Furthermore, the system is designed to facilitate user hierarchies, enabling companies and governments to gain insights into how customers utilize their assets. The database system and method for ABT token management and transaction tracking has a 1. Data Structure: The database system is constructed upon a resilient data framework, harnessing the strengths of both centralized and decentralized blockchain or ledger technologies. This architecture cultivates confidence and openness in the management of tokens. It harnesses the potential of distributed ledger technology to: register, authenticate, and safely preserve transactions across a network of interconnected nodes, guaranteeing the integrity and dependability of data.

2. Cardinal Relationship Model: At its core, the system implements a sophisticated cardinal relationship model that intricately defines connections between individual tokens and their associated securities, commodities, or derivatives. This model accommodates both fungible and non-fungible assets. The database system supports one-to-one, one-to-many, and many-to-many relationships, offering a versatile framework for tokenization strategies, including fractional ownership. This flexibility empowers administrators to tailor their tokenization approach to specific needs and requirements.

3. Tokenization of Securities: The database system excels in the tokenization of real-world securities, encompassing a wide range of financial instruments such as stocks, bonds, ETFs, and various derivatives. This process establishes a direct, legally backed link between tokens and the underlying securities. Each token issued within the system represents a precise, legally recognized claim on the corresponding security, ensuring full transparency, compliance with regulatory standards, and the protection of investors' rights.

4. Attribute Groups and Token Holder Structures: Within the system, tokens are intelligently categorized into attribute groups, each of which comes with a customizable set of attributes. These attribute groups provide fine-grained control over essential token properties. Administrators can define attributes governing: ownership, transferability, dividend distribution, and more, tailoring tokens to specific use cases while maintaining regulatory compliance and operational efficiency.

5. Transaction Tracking Mechanism: An innovative and robust transaction tracking mechanism is a cornerstone of the system's capabilities. It records, verifies, and securely stores every token transaction on the blockchain or ledger. This mechanism empowers administrators with detailed auditing and reporting functionalities, enabling comprehensive oversight of token movements, changes in ownership, and adherence to regulatory requirements. It ensures accountability, security, and transparency throughout the transaction lifecycle.

This database system represents a solution for ABT token management and transaction tracking, providing administrators with a reliable, transparent, and highly customizable platform for managing tokens and their associated financial instruments. Wallet data is imported into the system, maintaining a clear separation between the database and external wallet services. 1. Wallet Repository Types: Wallet Repositories are designed to store and manage information related to wallets, which represent the ownership of digital assets, including Asset Bound Tokens (ABTs). These repositories can be categorized into different types based on their intended usage. Explanations of each type follow:

Standard wallet repositories are used for typical wallet management and storage of wallet related data. They serve as the default storage for wallet information and are suitable for most use cases. Filtered Wallet Repositories: Filtered Wallet Repositories are used to create subsets or segments of wallet data from existing repositories.

They allow the administrator to define specific criteria or filters to select a subset of wallet records. This type is useful when the administrator needs to work with a specific group of wallets within the system. Random Wallet Repositories enable the administrator to randomly select wallets from a source repository. This can be beneficial when the administrator needs to perform random sampling or select wallets for specific purposes.

2. Sendable vs. Non-Sendable Wallet Repositories: The designation of a Wallet Repository as Sendable or Non-Sendable pertains to its relationship with communication channels and the ability to send messages or notifications to the wallet owners. Each designation means the following: Sendable Wallet Repositories are those that have a send relationship with communication channels. In the context of this system, this means that wallet owners associated with sendable wallet repositories can receive messages or notifications through various communication channels, such as email, SMS, or other methods. These repositories are typically used for engaging with wallet owners and facilitating communication.

Non-Sendable Wallet Repositories, on the other hand, do not have a direct send relationship with communication channels. Database for Asset Bound Tokens are used for reference and data storage purposes but are not intended for sending messages or notifications to wallet owners. Non-Sendable Wallet Repositories may contain important wallet-related information, but they are not actively used for communication. The categorization of Wallet Repositories into standard, filtered, or random types allows the administrator to organize and manage wallet data efficiently based on different use cases and requirements. Additionally, the designation as Sendable or Non-Sendable determines whether the wallet data in a particular repository can be used for communication purposes or if it is strictly for data reference and storage. This flexibility ensures that the system can adapt to a wide range of scenarios and administrator needs while maintaining clarity in data management.

1. Sendable Wallet Repositories: Using Sendable Wallet Repositories for communication with wallet owners is a practical way to facilitate two-way communication. This allows the administrator to send transaction notifications, important updates, or other relevant information directly to wallet users. It's important to ensure that communication through Sendable Wallet Repositories is secure and complies with privacy regulations, as cryptocurrency-related communications involve sensitive data.

2. Non-Sendable Wallet Repositories: Designating certain Wallet Repositories as Non-Sendable for storing data not intended for direct communication but essential for wallet management and analytics is a good practice. This clear separation between data used for communication and internal data can help maintain data integrity and streamline the database.

3. Data Retention: Implementing data retention policies within Wallet Repositories is crucial, especially for regulatory compliance. Ensuring that transaction history and related data are retained for the required period while adhering to data protection regulations is essential. This ensures that the administrator maintains a compliant and well-managed database.

4. Data Storage and Scalability: Storing data in an external SFTP storehouse and only calling data into the database when needed for analytics is a sound approach for scalability. It minimizes the storage burden on the primary database and allows the administrator to manage large volumes of data efficiently. This balances the need for communication, data management, and scalability, to ensure a robust and scalable system. Storing essential data on the blockchain and using an SFTP or similar external storage for additional analytics and management purposes provide the best of both worlds: the security and immutability of blockchain data, and the flexibility and scalability of external storage.

Blockchain technology is particularly well-suited for maintaining a transparent and tamper-resistant ledger of financial transactions, making it an excellent choice for recording cryptocurrency-related data. External storage allows the administrator to efficiently manage and analyze large volumes of data without overburdening the blockchain network.

Token Holder Connect in this database system is designed for managing token holders and their related attributes. It plays a crucial role in creating a unified view of token holder data by linking together various data sources and organizing them effectively. The components of Token Holder Connect:

1. All Token Holders: Definition: Represents a comprehensive list of all customers, "All Token Holders" in Token Holder Connect is a unified repository that contains information about every token holder or asset owner within the system. Function: All Token Holders serve as the foundation for this database, providing a complete overview of the token holder base. It's the starting point for building relationships and associating attributes with individual token holders.

2. Token Holder Data: Definition: Token Holder Data, refers to the collection of attributes and information associated with each token holder. These attributes can include names, wallet addresses, transaction histories, and any other data relevant to token holders. Function: Token Holder Data is the heart of Token Holder Connect. It allows an administrator of this database to create a detailed profile for each token holder, enabling the administrator to understand token holder behavior, preferences, and interactions.

3. Attribute Group (Attribute Groups):—Definition: Attribute Groups in Token Holder Connect represent collections

of related attributes that can be linked or associated with token holders. These attributes can come from various sources, including Token Attribute Repositories (TARs) and Wallet Repositories. Function: Attribute Groups help organize and categorize attributes logically. For example, the administrator might have an Attribute Group for “Transaction History” that includes attributes related to token transactions. This organization simplifies data management and retrieval for various use cases.

4. Transaction Records and History: Token Holder Connect is tightly integrated with Transaction Studio to provide administrators with a seamless experience. When transactions are initiated through Token Holder Connect, all transaction details, including buy, sell, or transfer actions, are recorded in Transaction Records within Transaction Studio. Administrators can easily access the complete transaction history for each digital asset directly from Token Holder Connect. Token Holder Connect essentially facilitates the creation of a unified view of token holders. It allows the administrator to link data from different sources, attribute groups, and repositories, making it easier to personalize interactions, analyze user behavior, and ensure compliance with regulatory requirements. This approach enhances the ability to manage and engage token holders effectively.

Cardinal relationships in Token Holder Connect are fundamental to how data is structured and linked within the database system. These relationships define how different data elements, such as token holders, their attributes, and repositories, are interconnected. Cardinal relationships in Token Holder Connect play a crucial role in establishing data associations.

1. One-to-One (1:1) Cardinal Relationship:—Definition: In a one-to-one relationship, each record in one repository is linked to exactly one record in another repository. This means that there is a unique and direct connection between records in the two repositories. Use Cases: One-to-one relationships are useful when you have a specific and unambiguous link between data. For instance, the administrator might establish a one-to-one relationship between a token holder’s profile in the “Token Holder Data” repository and their wallet information in the “Wallet Repository.”

2. One-to-Many (1:N) Cardinal Relationship: Definition: In a one-to-many relationship, each record in one repository can be linked to multiple records in another repository. This implies that one data element can be associated with several related data elements in another repository. Use Cases: One-to-many relationships are beneficial when there are multiple instances of related data. For example, a token holder may have multiple transactions recorded in the “Transaction Repository.” Each transaction can be linked back to the token holder, establishing a one-to-many relationship.

3. Many-to-Many (N:M) Cardinal Relationship: Definition: A many-to-many relationship allows multiple records in one repository to be associated with multiple records in another repository. This type of relationship is more complex and flexible, allowing for versatile data connections. Use Cases: Many-to-many relationships are useful in scenarios where data elements can have numerous cross-connections. For example, consider token holders participating in various investment groups. Each token holder can belong to multiple groups, and each group can have multiple token holders, creating a many-to-many relationship.

How Cardinal Relationships Work: Linking Data of Cardinal relationships are established by defining key fields in the repositories that serve as references. For example, a unique token holder connect ID in the “Token Holder Data”

repository may be used to link to wallet information in the “Wallet Repository” based on the same token holder connect ID. Data Integrity: Cardinal relationships help maintain data integrity. They ensure that data associations are accurate and that related records are properly connected. This is essential for creating a unified and reliable database.

Data Retrieval: Cardinal relationships simplify data retrieval and querying. The administrator can access related data elements easily, enabling the administrator to gather comprehensive information about token holders and their activities. Scalability: Cardinal relationships are adaptable to this database’s growth. As more data and repositories are added, an administrator can establish new relationships to accommodate evolving requirements.

Cardinal relationships in Token Holder Connect are a structural framework that allows an administrator to create meaningful connections between various data elements, ensuring that the administrator can effectively manage, analyze, and utilize the database’s information. They are the backbone of data organization and accessibility within this system.

Token Attribute Repositories (TARs) can be categorized into different types based on their intended usage. These categories help organize and manage data effectively within the database. Here’s an explanation of each type:

1. Standard Token Attribute Repositories: Standard TARs are the primary repositories for storing and managing token related data. They are designed for general token attribute storage and management and serve as the default storage for this type of information. Standard TARs are suitable for most use cases involving tokens.

2. Filtered Token Attribute Repositories: Filtered TARs are used to create subsets or segments of token attribute data from existing repositories. Administrators can define specific criteria or filters to select a subset of token attributes. This type is beneficial when working with specific groups of tokens or when segmenting data for targeted analysis or actions.

3. Random Token Attribute Repositories: Random TARs enable administrators to randomly select token attributes from a source repository. This can be useful for various purposes, such as random sampling, selecting tokens for specific actions, or conducting randomized analyses. The categorization of TARs into standard, filtered, or random types allows for efficient organization and management of token attribute data, catering to different use cases and requirements.

Token Attribute Repositories (TARs) are an essential component of this database system, responsible for storing and managing attributes related to tokens and their associated assets, such as securities, derivatives, commodities, and more. Entities can categorize TARs based on their intended usage and data retention requirements:

1. Sendable TARs: Usage: Sendable TARs are designed to store attributes that are meant for direct communication with users, asset holders, or token holders. These attributes might include information related to token ownership, transaction notifications, or other details that administrators need to know. Data Retention: Sendable TARs typically have shorter data retention periods because they contain information that is relevant for immediate communication and may become outdated quickly. For example, transaction notifications or account balance updates may be stored in Sendable TARs for a limited time. Example: If a user purchases tokens or engages in token transactions, the details of these transactions might be stored in a Sendable TAR for the purpose of sending transaction confirmations or updates.

2. Non-Sendable TARs: Usage: Non-Sendable TARs are used to store attributes that are essential for wallet management, analytics, and compliance but are not meant for direct communication with users. These attributes might include historical transaction data, asset valuations, or audit logs. Data Retention: Non-Sendable TARs can have longer data retention periods because they contain historical and analytical data that can be valuable for compliance reporting, auditing, and long-term analysis. These attributes help in understanding user behavior and the performance of different assets. Example: Storing the complete transaction history of tokens, including details like timestamps, quantities, and counterparties, in a Non-Sendable TAR can be crucial for regulatory compliance and historical analysis.

3. Data Retention Attributes: Usage: Data retention attributes are associated with how long the data in the TAR should be retained. These attributes help in managing data in compliance with regulatory requirements and business needs. They define the shelf life of data in the TAR. Data Retention Policies: Data retention attributes can specify different retention policies for Sendable and Non-Sendable TARs based on the type of data they store. For example, data in Sendable TARs might be retained for 90 days, while data in Non-Sendable TARs might be retained for several years. Example: A data retention attribute in a TAR could specify that transaction data in a Sendable TAR should be retained for 90 days, while transaction history in a Non-Sendable TAR should be retained for 7 years to meet regulatory compliance requirements.

By categorizing TARs into Sendable and Non-Sendable and applying appropriate data retention policies, the administrator can efficiently manage data related to tokens and assets, ensuring that users receive timely communication while maintaining historical data for compliance, analysis, and auditing purposes. Cardinal Relationships in Token Attribute Repositories (TARs):

Cardinal relationships play a crucial role in Token Attribute Repositories (TARs) within the database, where intricate connections between individual tokens and their underlying securities, commodities, derivatives or other financial instruments are defined.

These relationships enable versatile tokenization strategies, including fractional ownership and the management of both fungible and non-fungible assets. 1. One-to-One (1:1) Cardinal Relationship: Definition: In a one-to-one relationship, each record in one TAR is directly linked to exactly one record in another TAR. This means that there is a unique and precise connection between records in the two repositories, representing a one-to-one correspondence. In a one-to-one relationship, each token is directly linked to one specific security or derivative. This means that a single token represents the entirety of that underlying asset. Use Cases: One-to-one relationships are valuable when there is a specific, singular association between tokens and their corresponding attributes.

For example, a one-to-one relationship can be established between a token and its ownership details in the "Token Holder Data" TAR. Use Cases: A token representing one share of a company's stock has a one-to-one relationship with that stock.

2. One-to-Many (1:N) Cardinal Relationship: Definition: In a one-to-many relationship, each record in one TAR can be linked to multiple records in another TAR. This implies that one token or attribute can be associated with multiple related tokens or attributes in another TAR. One token can be associated with multiple commodities, securities, derivatives or other assets. Use Cases: One-to-many relationships

are beneficial when tokens have multiple attributes or when multiple tokens share common attributes. For instance, a token may have multiple transaction records associated with it, creating a one-to-many relationship between tokens and transactions. Use Cases: For fractionalized ownership, a token may represent partial ownership of several different real estate properties.

3. Many-to-Many (N:M) Cardinal Relationship: Definition: A many-to-many relationship allows multiple records in one TAR to be associated with multiple records in another TAR. This type of relationship is highly flexible, accommodating complex data connections. Many tokens may collectively represent ownership of one or more securities or derivatives, and conversely, one security or derivative may be represented by multiple tokens. Use Cases: Many-to-many relationships are particularly useful when tokens can have diverse and cross-cutting connections. For example, consider tokens representing ownership in various investment portfolios.

Each token can belong to multiple portfolios, and each portfolio can have multiple tokens, forming a many to many relationship. Use Cases: Multiple investors may collectively own a security or derivative through different tokens. How Cardinal Relationships Work in TARs: Establishing Links: Cardinal relationships are established by defining key fields in the TARs that act as references. For instance, a unique token ID in one TAR may be used to link to corresponding attributes in another TAR, based on the same token ID. Ensuring Data Consistency with Cardinal relationships are vital for maintaining data consistency. They ensure that data associations are accurate and that related records are correctly connected, preventing data anomalies.

Streamlining Data Access in Cardinal relationships simplify data access and retrieval. Administrators can efficiently retrieve related data elements, allowing for comprehensive analysis of token attributes and their connections. Scalability: Cardinal relationships are scalable and adaptable to accommodate the growth of the database. As more data and repositories are added, new relationships can be established to meet evolving requirements and support the database's expanding scope.

Cardinal relationships in TARs serve as the foundation for structuring, organizing, and managing the diverse attributes and attributes of tokens within the system. They enable administrators to establish meaningful connections between tokens and their associated data, facilitating efficient data management, analytics, and utilization in a dynamic and evolving database environment.

Transaction Studio is a core component of the database, designed to handle the management and analysis of transactions, compliance activities, and data relationships. It provides a comprehensive framework for organizing and understanding the database's financial ecosystem. Transaction Studio serves as the central hub for efficient management, monitoring, and analysis of financial transactions, compliance, and data relationships within the database. It offers a transparent and seamless experience within the financial ecosystem.

An in-depth breakdown of how the elements in Transaction Studio function: 1. Asset Holder List: Definition: The Asset Holder List is a dynamic record that maintains an up to date inventory of individuals or entities holding digital assets within the system. It includes details such as the names of asset holders, their contact information, and the specific assets they possess. Use Cases: The Asset Holder List serves several critical functions within the database, with a focus on tracking and managing asset ownership:

Ownership Tracking: The Asset Holder List provides a real-time snapshot of who holds specific digital assets within the system. This tracking ensures transparency and accountability in asset ownership.

Contact Information: It maintains contact information for asset holders, making it easy for administrators, auditors, and regulatory authorities to communicate with relevant parties when necessary. **Transfer Records:** The list includes records of asset transfers and ownership changes, creating a historical record of ownership transitions over time. **Compliance Oversight:** Compliance auditors and regulatory authorities can use the Asset Holder List to verify the accuracy of ownership information and assess compliance with regulatory requirements. **Reporting:** Administrators can generate reports based on the Asset Holder List, providing insights into asset ownership, trends, and potential compliance issues.

Due Diligence: When evaluating the ownership of specific assets, due diligence can be conducted by referring to the Asset Holder List. This helps ensure that assets are held by authorized parties. The Asset Holder List is a fundamental component for maintaining transparency, accountability, and compliance within the database. It provides a centralized repository of asset ownership information, streamlining ownership tracking and facilitating communication with asset holders. **2. Asset Groups: Definition:** Within the database, Asset Groups serve as repositories for related digital assets, encompassing a diverse range of financial instruments, including Asset Bound Tokens (ABTs), securities, commodities, derivatives, and various other financial assets. These groups are defined by their ability to bring together digital assets that share common characteristics or attributes. **Use Cases:** Asset Groups provide valuable functionality and utility within the database, supporting a multitude of purposes and administrator objectives:

Categorization: Asset Groups enable administrators to systematically categorize and organize digital assets based on specific criteria. For instance, an Asset Group could be established to include all ABTs representing an Exchange-Traded Fund (ETF) composed of securities. **Portfolio Management:** Asset Groups play a pivotal role in portfolio management. Administrators can create and manage portfolios of digital assets with similar characteristics, facilitating portfolio analysis, performance evaluation, and decision-making.

Compliance Management: Asset Groups are instrumental in compliance management. Regulatory requirements often differ based on the type and characteristics of digital assets. By grouping assets into distinct categories, compliance professionals can apply relevant regulatory standards efficiently. **Reporting:** Asset Groups simplify the process of generating reports and conducting analysis. Administrators can generate customized reports specific to asset categories, allowing for in-depth insights into the performance, risk exposure, and compliance status of asset groups.

Ownership Tracking: Asset Groups facilitate the tracking of ownership and transfers of digital assets. This functionality is particularly valuable in situations involving fractional ownership or complex ownership structures. Asset Groups serve as a foundational element for effective and structured management of digital assets within the database. They enhance portfolio management, streamline compliance efforts, and support robust reporting and analysis capabilities.

3. Transaction Categories: Definition: In the database, Transaction Categories are a means of classifying various types of financial transactions or activities. These categories

are essential for organizing and categorizing transactions based on their characteristics and attributes. **Use Cases:** Transaction Categories serve multiple purposes within the database, helping streamline transaction management and compliance. **Categorization:** Transaction Categories allow transactions to be organized into distinct groups based on their nature. For example, transactions related to stock trading activities can be categorized under a "Stock Trading" Transaction Category. **Reporting:** The categorization provided by Transaction Categories simplifies reporting and analysis. Administrators can generate reports specific to each category, providing insights into different transaction types.

Compliance: Transaction Categories play a vital role in compliance management. Regulatory requirements often vary depending on the type of transaction. By categorizing transactions, compliance professionals can ensure that the appropriate regulations are applied to each category. **Analysis:** Transaction Categories enable in-depth analysis of transaction data. Administrators can assess the performance of specific transaction types, identify trends, and make data-driven decisions. **Administrator Interface:** Transaction Categories enhance the administrator interface by providing an intuitive way to navigate and filter transactions based on their classification. This improves administrator experience and efficiency.

Transaction Records and History: Token Holder Connect is tightly integrated with Transaction Studio to provide users with a seamless experience. When users initiate transactions through Token Holder Connect, all transaction details, including buy, sell, or transfer actions, are recorded in Transaction Records within Transaction Studio. Users can easily access the complete transaction history for each digital asset directly from Token Holder Connect. **Manual Transaction Approval:** Administrators have the capability to manually review and approve transactions that meet predefined criteria requiring approval. This Manual Transaction Approval process extends its functionality to Token Holder Connect, ensuring seamless transaction oversight and management.

Key Aspects of Manual Transaction Approval: Initiation: When a transaction initiated through Token Holder Connect aligns with the predefined criteria necessitating approval, the Manual Transaction Approval process is triggered. **Administrator Review:** Administrators can access Transaction Studio to review pending transactions that require approval. This step allows administrators to thoroughly examine transaction details, ensuring compliance and security.

Transaction Approval: From Transaction Studio, administrators can approve transactions that meet the established criteria. This approval confirms the transaction's legitimacy and compliance with regulatory requirements. **Notification:** Token Holder Connect users involved in the transaction receive notifications of the approval status. This notification informs them of the transaction's progress and status change. **Manual Transaction Approval within Transaction Studio:** administrators maintain full control over the approval process, ensuring that transactions are thoroughly reviewed and compliant with the established criteria. This process enhances security, accountability, and regulatory adherence within the financial ecosystem.

Transaction Categories are a foundational component for effectively managing and classifying financial transactions within the database. They contribute to organized data management, compliance adherence, and insightful data analysis. **4. Compliance Auditors: Definition:** Within the database, Compliance Auditors are individuals or entities

entrusted with the responsibility of overseeing and ensuring regulatory compliance. Their primary role is to monitor and audit various aspects of the system to verify adherence to regulatory requirements and industry standards. Use Cases: Compliance Auditors play a crucial role in upholding compliance within the system, utilizing their authority for specific purposes:

Transaction Monitoring: Compliance Auditors actively monitor financial transactions to assess their compliance with applicable laws and regulations. They scrutinize transaction details, ownership, and other attributes. Asset Group Audits: Auditors review asset groups to ensure that they align with regulatory standards. This includes verifying the composition of asset groups and the compliance attributes associated with them. Data Relationship Audits: Compliance Auditors conduct audits of data relationships to verify the accuracy and completeness of attribute associations. This ensures that data is correctly linked and reflects the actual state of assets and transactions.

Audit Trails: Auditors maintain comprehensive audit trails, documenting their findings, assessments, and actions taken during audits. These audit trails serve as records of compliance oversight. Reporting: Compliance Auditors generate reports on compliance performance, highlighting areas of concern, potential violations, and recommended actions for remediation. Recommendations: In cases of non-compliance or issues identified during audits, Compliance Auditors provide recommendations and guidance for corrective actions.

Compliance Auditors act as internal guardians of compliance, working diligently to maintain regulatory adherence and industry standards within the system. Their monitoring and audit activities contribute to a compliant and regulated financial ecosystem. 5. Regulatory Authorities: Definition: Regulatory Authorities within the database represent external entities, including government agencies and financial regulatory bodies. They assume the role of establishing and enforcing compliance standards and regulations applicable to the system. Use Cases: Regulatory Authorities play pivotal roles in ensuring adherence to compliance standards and regulations, utilizing their access to shared compliance records and transaction data for specific purposes: Regulatory Oversight: Regulatory Authorities actively oversee compliance within the system, monitoring transactions, asset groups, and compliance-related activities.

Audit and Inspection: They have the authority to conduct audits and inspections of system operations, ensuring that regulatory requirements are met consistently. Investigations: In cases of suspected non-compliance or irregularities, Regulatory Authorities can initiate investigations into specific transactions or entities within the system. Data Access: Regulatory Authorities have access to shared compliance records, transaction details, and other relevant data sources. This access enables them to perform thorough reviews and assessments.

Compliance Enforcement: Regulatory Authorities are responsible for enforcing compliance standards and regulations within the system. They may impose penalties or sanctions for non-compliance. Reporting: These entities generate compliance reports, providing insights into the system's adherence to regulatory requirements. These reports are essential for maintaining transparency and accountability. Regulatory Authorities act as external guardians of compliance, ensuring that the system operates within the bounds of applicable laws and regulations. Their access

to data and oversight capabilities empowers them to fulfill their roles effectively, fostering a compliant and regulated financial environment.

6. Attribute Associations: Definition: Attribute Associations are structural components that establish connections between various data attributes or characteristics of digital assets and transactions within the database. Use Cases: Attribute Associations serve vital roles within the system, facilitating tracking and analysis of essential attributes related to digital assets: Data Linkages: Attribute Associations create linkages between data attributes, allowing for the correlation of information across different aspects of digital assets. For example, they link ownership details, transaction history, and compliance attributes to specific assets.

Ownership Tracking: These associations enable the system to track and record ownership changes and transitions for digital assets. Administrators can trace the history of asset ownership over time. Compliance Oversight: Attribute Associations play a pivotal role in compliance management. They connect compliance attributes to digital assets, ensuring that regulatory requirements and industry standards are met. Data Analysis: Attribute Associations provide a foundation for data analysis by organizing and relating attributes. Administrators can perform in-depth analyses to extract meaningful insights and patterns.

Asset Profiling: Administrators can create comprehensive profiles of digital assets by utilizing Attribute Associations to consolidate relevant attributes. These profiles offer a holistic view of asset characteristics. Audit Trails: The connections established by Attribute Associations contribute to creating audit trails for digital assets and transactions. These trails are valuable for accountability and regulatory compliance. Attribute Associations are instrumental in enhancing the system's ability to manage and analyze digital assets effectively. They provide the structural framework for organizing, correlating, and extracting insights from attribute-related data, making them a crucial component for asset tracking and compliance monitoring.

7. Transaction Records: Definition: Transaction Records are detailed records that capture comprehensive information about each financial transaction or activity within the database. Use Cases: Transaction Records serve essential functions within the system, providing a thorough account of individual transactions: Comprehensive Documentation: Transaction Records document each financial transaction comprehensively. They capture critical details such as the transaction type, timestamp, parties involved, and specific asset details. Transaction History: These records maintain a historical log of all transactions, allowing administrators to track the evolution of financial activities over time.

This historical data is invaluable for reference and analysis. Audit Trail: Transaction Records serve as an audit trail, providing a clear and chronological record of transactions. This audit trail aids in accountability, regulatory compliance, and dispute resolution. Data Analysis: Transaction Records offer a wealth of data that can be analyzed to gain insights into transaction patterns, trends, and performance. This analysis supports decision-making processes and strategic planning.

Regulatory Compliance: Transaction Records are crucial for regulatory compliance, as they provide the necessary documentation to demonstrate adherence to financial regulations and industry standards. Transparency: Making Transaction Records available ensures transparency, as stakeholders can review transaction details and verify the accuracy of financial activities within the system. Transaction Records

play a fundamental role in documenting, analyzing, and ensuring the transparency and compliance of financial transactions within the database. Their detailed and comprehensive nature makes them a valuable resource for administrators, auditors, and regulatory authorities.

8. Public Compliance Records: Definition: Public Compliance Records refer to records containing transaction details and compliance-related information that are accessible to regulatory authorities or the general public for the purposes of transparency and accountability. Use Cases: Public Compliance Records serve vital functions within the database, focusing on transparency and accountability to external stakeholders: Transparency: Public Compliance Records provide transparency by making certain compliance-related information available to external parties. This transparency showcases a commitment to openness and adherence to regulatory standards.

Regulatory Oversight: Regulatory authorities have access to these records to perform audits and reviews. This access enables regulatory bodies to verify compliance with applicable regulations and ensure that the database adheres to legal requirements. Accountability: By allowing external stakeholders, including the public and regulatory authorities, to review compliance records, the system promotes accountability. Administrators can assess whether the database complies with regulatory standards and industry norms. Audit Trails: Public Compliance Records serve as comprehensive audit trails, documenting compliance-related activities, actions, and transactions. This documentation aids in tracking compliance efforts and provides historical data for reference. Legal Compliance: Making compliance records accessible to external stakeholders aligns with legal requirements and regulatory obligations. It ensures that the database adheres to transparency regulations and facilitates external reviews.

Trust Building: The availability of compliance records fosters trust among administrators, investors, and regulatory authorities. It demonstrates a commitment to compliance and regulatory integrity. Public Compliance Records play a critical role in promoting transparency, accountability, and regulatory compliance within the database. By allowing external stakeholders to access compliance-related information, the system demonstrates its dedication to upholding industry standards and legal requirements. 9. Restricted Transactions: Definition: Restricted Transactions pertain to transactions that are subject to specific limitations or restrictions imposed by regulatory authorities or compliance auditors. Use Cases: Restricted Transactions serve essential functions within the database, primarily focused on ensuring compliance with regulatory requirements: Regulatory Compliance: These transactions are subject to stringent regulatory scrutiny and oversight. Compliance with established rules and regulations is paramount to avoid potential legal consequences.

Flagging Mechanism: Restricted Transactions are flagged within the system, highlighting their unique status. This flagging mechanism alerts relevant parties, such as compliance auditors and regulatory authorities, that further review and approval processes are necessary. Review and Approval: Transactions classified as restricted require thorough review and approval by authorized personnel. Compliance auditors or regulatory authorities are responsible for evaluating the transaction details to confirm adherence to regulatory requirements.

Documentation: Restricted Transactions necessitate meticulous documentation to substantiate their compliance with regulatory standards. This documentation serves as a

record of due diligence and helps demonstrate compliance efforts. Risk Mitigation: By subjecting certain transactions to additional scrutiny, restricted transactions mitigate the risk of non-compliance with regulatory guidelines. This proactive approach helps prevent potential regulatory breaches. Transparency: The designation of transactions as restricted enhances transparency by clearly indicating that these transactions have been subject to regulatory evaluation. This transparency fosters accountability and trust within the database.

Restricted Transactions play a pivotal role in maintaining regulatory compliance and ensuring that transactions align with established legal frameworks. They help prevent regulatory violations, protect the database's integrity, and demonstrate a commitment to upholding regulatory standards. 10. Mutually Agreed Restrictions: Definition: Mutually Agreed Restrictions refer to limitations or conditions that have been consensually agreed upon by multiple parties involved in a transaction. Use Cases: Mutually Agreed Restrictions play a crucial role in transaction management and compliance within the database.

They serve several essential purposes: Transaction Consistency: Mutually Agreed Restrictions ensure that transactions conform to the mutually accepted terms and conditions established by all parties involved. This promotes consistency and fairness in the execution of transactions. Transparency: These restrictions enhance transparency by clearly defining the constraints and obligations associated with a transaction. All parties are aware of and consent to the limitations, reducing the risk of disputes or misunderstandings. Customized Agreements: Mutually Agreed Restrictions allow for tailored agreements that suit the specific needs and preferences of the parties involved. This flexibility enables parties to negotiate and set restrictions that align with their unique circumstances.

Legal Compliance: By adhering to the mutually agreed-upon restrictions, transactions are more likely to meet legal and regulatory requirements. Parties can ensure that their actions are compliant with applicable laws and regulations. Conflict Resolution: In cases where disputes arise, these restrictions serve as a reference point for resolving conflicts. They provide a clear framework for addressing disagreements and determining whether parties have complied with the agreed-upon terms. Risk Mitigation: Mutually Agreed Restrictions help mitigate risks associated with transactions. Parties can proactively define and manage risks by setting restrictions that protect their interests.

Mutually Agreed Restrictions are a valuable mechanism for facilitating transactions with multiple stakeholders. They contribute to transactional transparency, legal compliance, and conflict resolution, ultimately fostering trust and accountability among all parties involved. 11. Attribute Filters: Definition: Attribute Filters are tools that refine and narrow down data based on specific attributes or criteria. Use Cases: Attribute Filters play a pivotal role in data management and analysis within the database. They are instrumental in the following scenarios: Data Refinement: Attribute Filters enable administrators to refine large datasets by specifying criteria relevant to their analysis or reporting needs. This process narrows down the dataset to include only the data points that meet specific attributes or conditions.

Focused Analysis by Administrators can employ Attribute Filters to concentrate on particular aspects of transactions or assets. For instance, they can focus on transactions within a specific time frame, assets of a certain type, or transactions involving particular parties. Compliance Checks: Attribute

Filters are essential for compliance checks. Administrators can filter data to identify transactions or assets that may require additional scrutiny based on predefined compliance attributes or regulatory criteria.

Customized Reporting: Attribute Filters allow for the creation of customized reports that present data in a tailored manner. Administrators can generate reports that highlight specific attributes or trends of interest. Performance Optimization: By reducing the volume of data to only what is relevant, Attribute Filters enhance data processing efficiency. This is particularly valuable for large-scale data analysis. Data Exploration: Attribute Filters facilitate in-depth data exploration by providing administrators with the ability to interact with the data in a way that aligns with their research or analytical objectives. Attribute Filters are versatile tools that empower administrators to navigate and interact with data efficiently. They are invaluable for extracting meaningful insights, ensuring compliance, and tailoring data presentations to meet specific needs.

12. Compliance Metrics: Definition: Compliance Metrics are quantifiable indicators used to assess and measure compliance performance. Use Cases: Compliance Metrics play a crucial role in tracking and evaluating adherence to regulatory requirements. They provide valuable insights into the system's compliance with industry standards and regulations. Here's how Compliance Metrics are utilized: Performance Assessment: Compliance Metrics serve as benchmarks for evaluating how well the system complies with various regulatory requirements and industry standards. They allow for an objective assessment of compliance performance. Monitoring Progress using these metrics provides a means to continuously monitor and measure progress towards compliance goals. By tracking specific indicators, administrators can identify areas that require improvement or further attention. Regulatory Reporting: Compliance Metrics contribute to the preparation of regulatory reports and documentation.

They offer quantifiable evidence of compliance efforts, making it easier to demonstrate adherence to authorities and auditors. Decision-Making: Compliance Metrics inform decision-making processes by providing data-driven insights. Administrators can make informed choices based on the performance indicators to enhance compliance strategies. Identifying Trends: Over time, Compliance Metrics can help identify trends and patterns related to compliance. This allows administrators to proactively address potential issues and adapt to changing regulatory landscapes.

Compliance Metrics are an integral part of maintaining a compliant and well-regulated system. They enable administrators to gauge the effectiveness of compliance efforts, make informed decisions, and demonstrate a commitment to meeting regulatory requirements and industry standards. 13. Tracking: Definition: Tracking involves monitoring, recording, and storing activities, changes, and events within the database. Use Cases: Tracking is essential for maintaining an audit trail, ensuring data integrity, and providing a history of actions and transactions for compliance, security, and accountability purposes. Tracking serves the following critical functions: Audit Trail: It creates a detailed record of all activities, changes, and events, allowing for comprehensive audits of administrator actions, system modifications, and transaction history.

Data Integrity: Tracking helps safeguard data integrity by providing a clear account of all changes made to the database. This ensures that data remains accurate, reliable, and tamper-proof. Security: It plays a pivotal role in enhancing security measures by monitoring administrator and database

user access, authentication, and authorization. Suspicious or unauthorized activities can be quickly identified and addressed. Accountability: Tracking establishes accountability by attributing actions and changes to specific administrators, database users or entities. This promotes transparency and responsibility within the system.

Tracking is an integral part of the database's operation, contributing to its robustness, security, and reliability. By maintaining an audit trail, upholding data integrity, enhancing security, and enforcing accountability, tracking serves as a critical pillar for ensuring compliance, security, and accountability within the system. 14. Profile and Preference Center: Definition: The "Profile and Preference Center" within Transaction Studio is a dedicated feature designed for users to manage and customize their personal profiles, communication preferences, and interaction history. It empowers users to have full control over how they engage with the system while maintaining their privacy and ensuring a personalized experience.

The Profile and Preference Center serves several critical functions within the database: Profile Management: Users can update and maintain their profiles, including personal information, token holder details, and authentication settings. This feature ensures that user profiles remain accurate and up-to-date. Communication Preferences: Users have the ability to define their communication preferences, specifying how they wish to receive notifications, updates, and alerts from the system. This includes choices related to wallet messages, wallet notifications, and other communication channels.

Preference History: The center keeps a detailed record of users' historical preferences, allowing them to review past choices and make adjustments as needed. This historical data ensures that administrators can track and reference their previous interaction preferences. User Support: Users can access dedicated user support resources, such as FAQs, guides, and contact options, directly from the Profile and Preference Center. This feature ensures that users have easy access to assistance whenever needed.

Privacy Controls: Privacy settings are an integral part of the center, allowing users to define the level of data sharing and visibility within the system. Users can adjust privacy settings to align with their comfort and requirements. The Profile and Preference Center puts users in the driver's seat, offering a seamless and intuitive way to manage their experience and interactions within the database. By providing control over profiles, communication settings, and support resources, users can receive communication from the system with confidence and ensure that their preferences are respected, all while preserving their privacy. Compliance management remains the responsibility of administrators and professionals on the backend, ensuring that regulatory standards are met with precision.

AssetFlow Automation Suite is designed to cater to the specific requirements of large entities engaged in the utility of Asset Bound Tokens (ABTs) and the management of digital assets and financial instruments. AssetFlow Automation Suite provides a comprehensive set of automation tools: 1. Scheduled Workflows: Configure scheduled workflows to automate routine tasks like data imports, token issuance, or compliance checks. Ensure precise data management and timely operations by scheduling workflows at predefined intervals.

2. File Integration Automations: Deploy File Integration Automations to seamlessly receive and process external data files. This feature streamlines data imports when a file is dropped, making it efficient, even when dealing with sub-

stantial transaction volumes or asset updates. 3. Event Driven Automations: Set up Event Driven Automations to respond swiftly to specific occurrences within the database. For instance, when a user initiates a token transfer or requests compliance verification, Event Driven Automations execute the necessary actions automatically. 4. SQL Data Query: Harness SQL Data Query such as action query, a select query, or a combination of both to retrieve and segment data within the database. This functionality is particularly valuable for creating targeted asset or user groups based on attributes like asset ownership, compliance status, or transaction history.

5. Data Integration Automations: Automate the importing process of Asset Groups or Repositories with external files using the Data Integration Automations. This feature facilitates the efficient management of user data and asset information, ensuring the database remains current. 6. Custom Workflow: Create customized Workflows to execute intricate operations within the database. These tailored workflows align with specific business rules and requirements, providing flexibility and precision. 7. Data Filtering: Implement Data Filtering to refine and segment data based on predefined criteria. This capability proves beneficial when you need to isolate specific attributes or assets for targeted actions.

8. Data Extraction: Automate data extraction from the database using Data Extraction. This functionality generates reports, compliance documentation, or data backups, ensuring crucial information is readily accessible. 9. Workflow Orchestration: Strategically introduce delays in the automated processes with Workflow Orchestration. For example, you can include wait periods for compliance verifications or to synchronize asset updates. 10. Workflow Control: Retain complete control over running workflows by pausing, skipping, or stopping them as required with Workflow Control. This flexibility enables efficient operations and real-time adjustments.

11. Workflow Duplication and Management: Empower administrators to duplicate and customize workflows to address various scenarios effectively. Additionally, provide the option to manage and remove workflows that are no longer relevant, ensuring a streamlined interface. 12. Workflow Monitoring and Performance: Implement tools to monitor workflow history and performance. Keep tabs on successful runs, error tracking, and performance metrics, enabling continuous optimization of the automated processes.

13. Transaction Management: Assetflow Automation Suite incorporates Transaction Management features from Transaction Studio to automate various financial processes. For example, automated routines can be configured to initiate buy or sell transactions based on predefined criteria, such as specific asset performance metrics or market conditions. This streamlines asset management processes and reduces manual intervention. 14. Transaction Approval Workflow: The Assetflow Automation Suite integrates seamlessly with the Transaction Approval within Transaction Studio. Automated routines can be designed to follow approval processes when necessary. If a transaction meets specific criteria that require approval, the automation triggers the workflow, and Administrators can review and approve transactions through the suite.

15. Transaction Notifications: Assetflow Automation Suite provides notification capabilities to alert users about automated transaction activities. When an automated transaction is executed or requires attention, notifications are sent to designated users, ensuring they are informed and can take

appropriate actions. 16. Reports: Empowers users to track and analyze the performance of their marketing campaigns and customer journeys. The suite offers robust reporting capabilities that provide valuable insights into customer behavior, campaign effectiveness, and journey outcomes, including transactions and transfers of ABTs and other digital assets.

Key Features of Reports in Assetflow Automation Suite: 1. Comprehensive Data: Reporting features encompass a wide range of data, including transactions and transfers of ABTs and other digital assets. Users gain a holistic view of how customers engage with marketing campaigns and interact with digital assets. 2. Customized Reports: Users can create customized reports tailored to their specific needs and objectives. This flexibility allows for the inclusion of relevant metrics and data points related to both marketing activities and asset transactions.

3. Integration with Transaction Studio: Assetflow seamlessly integrates with Transaction Studio, providing users with access to additional data from Asset Group Reports, as well as transaction and transfer data. This integration enhances the depth of insights available to users, allowing them to correlate marketing campaign data with asset-specific information and financial transactions. 4. Performance Tracking: Users can track the performance of marketing campaigns and customer journeys, as well as monitor the impact of asset transactions and transfers. This includes monitoring key performance indicators (KPIs), conversion rates, customer engagement levels, and financial transaction data.

5. Data Visualization: Reports in Assetflow Automation Suite utilize data visualization techniques such as charts, graphs, and dashboards to present information in a visually appealing and easy-to-understand manner. This aids users in quickly identifying trends and patterns related to both marketing activities and financial transactions. 6. Data Segmentation: Users can segment data within reports to gain insights into specific customer groups or campaign segments, as well as transaction and transfer patterns.

This segmentation capability supports targeted marketing strategies and allows for a deeper understanding of asset-related activities. 7. Export and Sharing: Reports can be exported in various formats and shared with team members or stakeholders. This facilitates collaboration and data-driven decision-making across the organization, including discussions related to marketing campaigns and financial transactions. The reporting features within Assetflow Automation Suite, users can measure the effectiveness of their marketing efforts, optimize customer journeys, and make data-driven decisions.

Transactions and transfers of ABTs and other digital assets in reports provides a comprehensive view of customer behavior and financial activities, enabling organizations to gain valuable insights into both marketing and financial aspects of their operations automatically. The Assetflow Automation Suite empowers large entities to automate mission-critical tasks, streamline operations, and elevate their overall experience within the financial sector. Whether it's data management, compliance checks, or asset transfers, these features ensure that processes are efficient, error-free, and tailored to meet the precise business needs of an entities financial ecosystem.

Importing data into the database is a critical process that ensures the system remains up-to-date and accurate. There are several methods and mechanisms in place to facilitate data import, including API integration for entities seeking to access and utilize the database programmatically. 1. Manual

Data Import: Token Holder Connect: Administrators utilizing the database can manually import data into the system through Token Holder Connect. This user-friendly interface allows for the input of various data types, user profiles, ownership details, and transaction records. Entities can access Token Holder Connect through a secure login and input data directly into the system, ensuring data accuracy and completeness.

Transaction Studio: Transaction Studio serves as a platform for managing and recording transaction data. Entities, such as administrators and financial institutions, can manually input transaction details, including trade types, asset information, timestamps, and parties involved. This manual data entry ensures that all transaction-related information is accurately captured and stored within the database. 2. Automated Data Import through AssetFlow Automation Suite: Scheduled Workflows: AssetFlow Automation Suite offers Scheduled Workflows that can be configured to import data at specific intervals. For example, it can automate the import of daily market data, ensuring that asset valuations and prices are up-to-date.

File Integration Automations: This feature allows for seamless external data file ingestion. Administrators can set up File Integration Automations to receive, process, and import external data files into the database. This is particularly useful when dealing with large volumes of data, such as regulatory reports or market feeds. Event-Driven Automations: Event-Driven Automations can initiate data import processes in response to specific events or conditions. For instance, when a new user is onboarded or when a compliance audit is requested, an Event-Driven Automation can automatically import the necessary user data or compliance records.

API Integration: Entities seeking programmatic access to the database can utilize APIs for data import. The database provides well-documented APIs that allow external systems to securely interact with the database. Entities can use these APIs to import and export data, facilitating seamless data integration with their existing systems and workflows. 3. Data Validation and Transformation: Before data is imported into the database, it undergoes validation and transformation processes to ensure data accuracy and consistency. This includes checks for data format, completeness, and adherence to predefined data schemas and standards.

4. Security Measures: All data imports, whether manual or automated, adhere to stringent security measures. Secure Sockets Layer (SSL) encryption and authentication protocols are in place to safeguard data during transmission. Additionally, role-based access controls and permissions ensure that only authorized administrators and entities can perform data imports. 5. Error Handling and Logging: The database includes comprehensive error handling and logging mechanisms. In the event of data import errors or issues, detailed logs are generated to facilitate troubleshooting and resolution. Notifications can also be sent to designated personnel or administrators to address data import issues promptly.

6. API Integration for External Entities: The database offers a RESTful API that external entities can leverage to programmatically interact with the system. This API allows for secure data exchange, including data import and export. External entities can use the API to integrate the database with their own systems, ensuring seamless data flow and synchronization. Data import into this database is a multifaceted process that accommodates both manual and automated methods. AssetFlow Automation Suite enhances auto-

mation capabilities, while robust security measures, validation, and error handling ensure data accuracy and integrity.

The API integration further extends the database's accessibility, allowing external entities to seamlessly interact with and utilize the database's rich dataset for their specific financial needs. The database system provides multiple options for the location and type of files that can be imported or exported. Here are the available file location types along with their descriptions: 1. Amazon S3, Google Cloud Storage, or Microsoft Azure Blob Storage: Description: This option allows you to transfer files directly to or from the external cloud storage location. It offers the advantages of fast file transfer and provides granular control over file and folder permissions.

You can seamlessly integrate the database with cloud storage services like Amazon S3, Google Cloud Storage, or Microsoft Azure Blob Storage for efficient data exchange. 2. Database Enhanced FTP Site: Description: The Enhanced FTP Site is a part of the database system. It enables the transfer of files to or from the default Import and Export directories or any other subfolder within the Enhanced FTP. This feature provides a built-in FTP capability that simplifies file transfer operations within the database. 3. Database Safehouse: Description: The Safehouse serves as a secure data storage and transfer mechanism within the database. It allows for the encryption and decryption of files before import or extraction without exposing these files to the Enhanced FTP directories. Access to the Safehouse is restricted to authenticated administrators only, and it resides on highly redundant and highly available central storage servers, ensuring data security and integrity.

4. External FTP, SFTP, or FTPS: Description: This option enables the transfer of files to and from your own FTP, SFTP, or FTPS site. You can integrate the database with your external file transfer service for data exchange. Whether you use a standard FTP server, a secure SFTP connection, or FTPS for added security, the database can accommodate your specific file transfer requirements. These diverse file location types offer flexibility and compatibility with various storage and transfer methods, ensuring that the database can seamlessly import and export data from multiple sources and destinations while adhering to security and compliance standards.

The Database for Asset Bound Tokens (ABTs) and Digital Assets exhibits several characteristics that classify it as a database. 1. Tabular Structure: The database stores data in structured tables with predefined schemas. These tables consist of rows and columns, where columns represent attributes or fields, and rows represent individual records. For instance, Token Attribute Repositories (TARs) within the database have a tabular structure, where each row corresponds to a specific token, and columns contain attribute-related information, including ownership, transaction history, and other pertinent data.

This tabular structure aligns with the fundamental organization of relational databases. 2. Schema: Relational databases require a predefined schema that specifies the structure of each table. This schema includes information about data types, constraints, and relationships between tables. In the context of the ABT database, the presence of TARs suggests a predefined structure for these repositories, which encompasses ownership details, transaction history, and various attributes. Enforcing this structure ensures data integrity, as it imposes constraints on how data can be entered and manipulated.

3. ACID Transactions: This database ensures data consistency and reliability through mechanisms such as transaction handling. ACID (Atomicity, Consistency, Isolation, Durability) transactions are a hallmark of relational databases, ensuring that all database operations are either completed in their entirety or completely undone in case of failure. This system provides a robust transactional support, the ABT database aligns with the ACID principles commonly associated with relational databases. 4. SQL Query Language:

This database supports a query language similar to SQL (Structured Query Language). administrators can query the database using SQL queries or data filters Attribute Filters). SQL is renowned for its powerful capabilities in performing complex queries and joins, which is crucial for extracting meaningful insights from the database's structured data. This feature is synonymous with relational databases, where SQL is the standard language for data manipulation and retrieval. The database for ABTs embodies the core characteristics of a relational database, including a tabular structure, predefined schema, support for ACID transactions (implicitly), and the utilization of a query language akin to SQL.

These attributes collectively establish the database's identity as a structured and organized system for storing and managing data related to Asset Bound Tokens and their associated attributes. Segmenting data in this database is a crucial aspect of managing Asset Bound Tokens (ABTs) and digital wallets efficiently. This process involves dividing the database's records into distinct groups or segments based on specific criteria. Here's how data segmentation works within the database, incorporating filtered repositories, data filters, SQL queries, and the audience segmentation manager:

1. Filtered Repositories: Filtered repositories are specialized data containers within this database designed to hold subsets of data based on specific criteria or attributes. For instance, you can create filtered repositories for ABTs of a particular asset type, owned by specific users, or involved in recent transactions. To segment data using filtered repositories, customize these repositories to match administrator segmentation requirements. For example, you might establish a filtered repository for "High-Value ABT Holders" or "Recent ABT Transfers." Once defined and populated, filtered repositories provide easy access to segmented data according to your criteria.

2. Data Filters: Data filters consist of rules or conditions applied to the data to isolate specific records that meet certain criteria. Within this database, data filters are valuable for segmenting ABTs, wallet information, or transaction records. For instance, you can create a data filter to extract all ABTs issued in the last month or identify wallet holders who meet specific compliance criteria. Data filters offer flexibility in dynamically segmenting data, and you can save them for repeated use. 3. SQL Queries: SQL queries play a pivotal role in segmenting data within this database. SQL (Structured Query Language) empowers you to craft intricate queries to retrieve specific data based on user-defined conditions. In the context of this database, SQL queries provide a highly customized approach to data segmentation. For example, you might use SQL to fetch a list of users holding ABTs from different asset classes or identify transactions exceeding a certain value threshold.

SQL queries grant precise control over data segmentation, enabling extraction of exactly the information needed. 4. Audience Segmentation Manager: The audience segmentation manager is a feature tailored to segment data for targeted communication or actions within this database. It allows you to create segmented groups of users, ABTs, or

wallets based on various attributes. For instance, you can utilize the audience segmentation manager to create audience segments like users who recently acquired ABTs or those requiring compliance verification.

Once audience segments are defined, they can be seamlessly integrated into communication campaigns, compliance checks, or other actions tailored to the unique needs of each segment. Data segmentation within this database is a versatile process encompassing filtered repositories, data filters, SQL queries, and the audience segmentation manager. These tools provide the capability to organize and access data with precision, facilitating targeted actions, report generation, compliance checks, and improved user engagement. Whether segmenting ABTs, wallets, or transaction data, the segmentation capabilities of this database offer the flexibility and control necessary to meet specific business requirements within the financial sector.

Message building is creating messages for communication with wallets in this database involves various elements, including Asset Personalization Tag, Dynamic Content, Message Templates, Content Blocks, and AssetScript (scripting capabilities). Let's delve into how message building works within this database: 1. Asset Personalization Tags: Asset Personalization Tags are personalized strings that allow you to insert dynamic information into the messages. These tags act as placeholders that get replaced with specific wallet-related data when the message is sent. For example, you can use an Asset Personalization Tag like %%WalletBalance%% to personalize messages with the recipient's current wallet balance.

2. Dynamic Content: Dynamic Content are dynamic content elements that enable you to create message variations that are automatically selected based on specific conditions or recipient attributes. For instance, you can use Dynamic Content to display different content to wallet holders based on their asset type, transaction history, or compliance status.

3. Message Templates: Message Templates are pre-designed message layouts tailored for wallet-related communication. These templates provide a consistent and visually appealing format for the messages. A user can choose from a library of Message Templates or create custom ones to suit various communication needs, such as transaction notifications, compliance updates, or asset statements.

4. Content Blocks: Content Blocks are modular components that you can use to assemble the messages. These blocks can contain text, images, links, and other content elements. When building a message, a user can arrange Content Blocks to create a message structure that conveys information effectively to wallet holders.

Testing content within this database, particularly for communication purposes, involves ensuring that messages sent to wallet holders are accurate, compliant with regulations, and successfully connect to the intended wallet addresses. Here's how testing content would work in this context: 1. Token Holder Preview: Before sending any messages to wallet holders, administrators have the option to utilize a "Token Holder Preview" feature within the database. Token Holder Preview allows administrators to review how the message content will appear to wallet holders before it is sent. This ensures that the message is formatted correctly, and any personalized information, such as token balances or transaction details, is accurate. Administrators can select specific wallet holders or groups to preview the message and verify that the content is tailored appropriately to the recipients.

2. Message Compliance (CAN-SPAM and GDPR Regulations): Compliance checks within the database now

encompass both CAN-SPAM and GDPR regulations. Before sending any messages to wallet holders, administrators can run compliance checks on their message content to ensure it adheres to these regulations. The database verifies that messages include essential elements required by both regulations, such as an opt-out mechanism, a valid physical address, accurate sender identification, and explicit consent for data processing when applicable. Administrators receive guidance and recommendations to maintain compliance with both CAN-SPAM and GDPR when creating message content. 3. Connects to Wallet Address: To test whether a message successfully connects to the intended wallet address, administrators can use a "Connectivity Test" feature. This feature allows administrators to simulate the message delivery process. Administrators can select specific wallet addresses or groups and send test messages. The database monitors the delivery process and provides real-time feedback on whether the message was successfully delivered to the wallet address or if any issues occurred.

4. Message Personalization and Dynamic Content: Testing content also involves verifying that dynamic content and personalization are functioning correctly within the messages. Administrators can use placeholders and dynamic content tags in their message templates. During testing, the database ensures that these placeholders are replaced with the accurate and up-to-date information for each wallet holder. Administrators can preview how dynamic content will appear for specific wallet holders to confirm that personalization is working as intended. 5. Testing Variations: Administrators have the flexibility to test different variations of message content. For instance, they can create A/B tests to assess which message content or format performs better in terms of engagement or compliance. The database tracks the performance of these variations and provides insights into which content resonates most with wallet holders.

6. Delivery and Read Receipts: As part of the testing process, the database tracks delivery and read receipts. Administrators can monitor whether wallet holders have received and opened the messages. This information is valuable for assessing the effectiveness of communication and making necessary adjustments to message content. Testing content within this database for communication involves a multifaceted approach. Administrators can preview message content, ensure compliance with regulations like CAN-SPAM, verify successful delivery to wallet addresses, test dynamic content and personalization, and assess message variations. By conducting comprehensive testing, administrators can optimize their communication strategies, maintain compliance, and deliver accurate and engaging messages to wallet holders.

Reporting within this Database for Asset Bound Tokens (ABTs) and digital wallets is facilitated through a combination of Reports, Data Insight, and Send Logs. Let's explore how these components work together to provide comprehensive reporting capabilities:

1. Reports: Reports in this database are customizable tools that allow administrators to extract, analyze, and visualize data based on their specific requirements. These reports can cover a wide range of aspects related to ABTs, wallets, transactions, compliance, and more. Administrators can create custom reports by selecting relevant data fields, applying filters, and defining criteria for data extraction. These reports can be scheduled for regular updates and distribution to stakeholders. Sample reports in this database may include: ABT Transaction History Report: Provides a detailed overview of all ABT transactions, including timestamps,

involved parties, and transaction amounts. Wallet Portfolio Summary: Offers insights into the composition of wallet portfolios, categorizing assets by type, value, and ownership. Compliance Verification Status: Tracks and reports on compliance verification status for wallet holders, ensuring regulatory adherence. Asset Diversification Analysis: Analyzes the distribution of assets within wallets to assess diversification levels.

2. Data Insight: Data Insight is a set of predefined, structured collections of data that provide specific insights into various aspects of the database. These views offer valuable information that can be used for reporting and analysis. Within this database, you may find Data Insight such as: ABT Transaction Data Insight: Contains detailed information on all ABT transactions, including sender and receiver details, transaction types, and timestamps. Wallet Holder Data Insight: Provides comprehensive profiles of wallet holders, including ownership details, compliance status, and contact information. Asset Type Data Insight: Focuses on categorizing assets by type, enabling a deeper understanding of the asset composition within the database.

3. Send Logs: Send Logs are records of all messages, notifications, or communications sent from the database to wallet holders or other stakeholders. They capture essential information about the sent messages. Send Logs can be invaluable for auditing, tracking communication history, and ensuring the successful delivery of critical notifications. Information typically found in Send Logs includes message content, recipient details, timestamps, and delivery status. How Reporting Works in This Database: Administrators access the Reports section of the database to create, customize, and run reports. They can select the appropriate report type, define criteria, and choose data fields to include in the report.

Data Insight serves as a foundational source of data for reports. Administrators can reference specific Data Insight when creating reports, ensuring that the data used for reporting is consistent and up-to-date. Reports can be generated on-demand or scheduled for regular updates. Scheduled reports can be configured to be sent to designated recipients, promoting transparency and timely access to information. Send Logs play a vital role in tracking the delivery and status of messages and notifications sent to wallet holders. These logs provide a comprehensive history of communication events. Reporting within this database empowers administrators to make informed decisions, monitor compliance, track transaction history, and gain insights into the overall state of ABTs and digital wallets. Whether it's assessing the performance of wallet portfolios, verifying compliance, or analyzing transaction trends, reporting capabilities ensure that stakeholders have access to the data they need for effective management and decision-making.

Example: A User's ABTs Purchase-Buying a Stock. 1. User Registration: The user registers on the platform and creates an account. During registration, the user provides personal information and is assigned a unique Token Holder Connect Key, which serves as their identifier within the system. This Token Holder Connect Key is used for linking various records and activities to the user. 2. Creating a Wallet: After registration, the user creates a wallet to manage their assets. The creation of a wallet is recorded in the database as follows: A new Wallet Repository is generated for the user.

This Wallet Repository is categorized as "Standard" and designated as "Sendable" since it will be used for both communication and transaction channels. The Wallet Repository is associated with the user's Token Holder Con-

nect Key, linking the user to the ownership of the wallet. 3. Buying a Stock Using ABTs: The user decides to invest in a stock using their ABTs. Here's what happens during this process: Token Creation: The user initiates a request to create a new ABT for the stock(s) they want to purchase. This request triggers the generation of a new Token Attribute Repository (TAR) specifically for the stock(s). The Token Attribute Repository is associated with the user's Token Holder Connect Key, linking the user to the ownership of this ABT. Transaction Execution: The user places an order to purchase the stock(s) using the ABT. This transaction is recorded in the system.

The database logs details of the transaction, including: The user's Token Holder Connect Key as the buyer. The ABT's Token Attribute Repository as the asset being traded. The stock as the underlying asset. Transaction date and time. Transaction status (e.g., pending, completed). Any other attributes. 4. Administrator's View: From the administrator's perspective, they have access to a dashboard or interface that provides insights into user activities. When the user's first ABTs purchase is made, the administrator sees the following: User Activity Log: In the user activity log, the administrator can see a new entry indicating the user's purchase of the stock using ABTs. This entry includes details such as the user's Token Holder Connect Key, the ABT's TAR, and the stock information. Asset Ownership Records:

The administrator can view asset ownership records, which show that the user now owns a specific quantity of the stock represented by the ABT. This ownership is associated with the user's Token Holder Connect Key and the Token Attribute Repository linked to that ABT. Transaction History: The transaction history log reflects the stock purchase transaction, including the date, time, and status. The administrator can confirm that the transaction has been successfully executed. 5. Regulatory Compliance: Additionally, the system ensures that the transaction adheres to any regulatory requirements. For example, if there are rules specifying that only accredited investors can buy certain securities, the system verifies the user's status before allowing the purchase. This demonstrates how the database system manages user activities, records ownership of assets through ABTs, and provides administrators with insights into these activities.

The use of Token Holder Connect Keys, Token Attribute Repositories, and Wallet Repositories facilitates data organization and tracking, ensuring a comprehensive and compliant record of transactions and asset ownership. Certainly, this database requires a centralized setup location to manage various aspects and features effectively. Similar to Marketing Cloud Setup, this setup for the database, referred to as "AssetFlow Setup," provides users with the tools and resources needed for seamless configuration and administration. Below is a detailed breakdown of AssetFlow Setup, incorporating the new names and features relevant to this database: Database Setup serves as a centralized hub for managing and configuring the database account. This comprehensive setup area offers a range of tools and resources to ensure smooth account management and optimal utilization of the database's features. Navigation Menu: The Navigation Menu provides easy access to various sections within the database Setup. It is categorized into sections such as "Administration," "Platform Tools," and "Settings," allowing users to quickly locate the setup pages they need.

Quick Search: Quick Search enables administrators to find specific setup pages by entering relevant search terms. This feature streamlines the process of accessing administrative tools, ensuring efficient navigation throughout the

setup. Dashboard: The Dashboard section of the database setup offers key insights and metrics related to your database account. These metrics may include: ABT Data Overview: A graphical representation of ABT data within your account, displaying the number of ABTs issued, active ABTs, and more. Compliance Check Status: An overview of compliance verification status, indicating the number of completed verifications, pending checks, and compliance-related alerts. Wallet Holdings Analysis: Insights into wallet portfolios, categorizing assets by type, value, and compliance status. User Management Summary: An overview of user accounts and their roles within the database.

Resource Links: Database setup includes a section with links to essential resources, including: System Status: Provides real-time updates on the operational status of the database system. Release Notes: Access the latest release notes to stay informed about updates and improvements. Knowledge Base: A knowledge base to access documentation, guides, and tutorials for the database. Training: Access training materials and resources to enhance your proficiency in using the database. Setup Assistant: The setup assistant guides administrators through the initial configuration of their database account. It provides a prioritized task list to ensure users make the most of the database's capabilities from the start.

Limits: The database setup includes details on usage limits and constraints specific to your database account. It outlines both internal and external limitations that may affect your usage of the database. Password Management: Password Management in the database allows users to reset lost or forgotten passwords securely. This automated process ensures the security of user accounts while providing a straightforward password recovery mechanism.

Account Settings: Account administrators have access to the Account Settings workspace, where they can control configuration information. This workspace contains essential account details, including database settings and user permissions. Feature Configuration: The database setup enables administrators to review and configure settings for various features offered by the database. This includes customization options for compliance checks, automated workflows, and data import/export processes. Security Settings: The database's Security Settings encompass parameters related to session timeout, access controls, and data encryption.

These settings enhance the overall security of the database account. User Management: Administrators can access the User Management section to create, modify, or deactivate user accounts within the database. It also allows administrators to assign roles and permissions to users based on their responsibilities. Business Units: The database supports the creation of business units to manage data access and sharing. Administrators can define user roles within each business unit, control data access, and configure filter criteria for token holders. Alert Manager: The database's Alert Manager allows administrators to designate recipients for critical system alerts. In the event of system errors or issues, notifications are sent to specified email addresses, providing insights into the problem's nature. FTP Accounts: Administrators can assign FTP privileges to individuals or teams within the database account.

FTP accounts facilitate secure file transfers to and from the database, ensuring efficient data management. File Locations: File Locations in the database represent external file storage locations, such as cloud storage or FTP sites. Users can configure these locations to facilitate secure file transfers between the database and external repositories. Key Man-

agement: Key Management allows administrators to manage security keys and other encryption-related options. These keys are utilized for data encryption, message signing, and implementing secure single sign-on (SSO) for the database account.

Branding: Branding enables users to customize the look and feel of their database account. It allows for the application of branding elements, such as color schemes, based on uploaded logos, providing a branded user experience. Single Sign-On (SSO) Authentication: The database supports single sign-on (SSO) authentication via SAML 2.0. This feature allows third-party identity providers to authenticate users to both internal systems and the database, enhancing security and user convenience. Account Login Access: Account Login Access permits the database support to log in to user accounts for specific configurations or troubleshooting purposes. This feature streamlines support interactions and issue resolution.

SSL Certificates: SSL Certificates enhance security by encrypting page-based interactions. This ensures the confidentiality of sensitive information during interactions with subscribers and contacts. Setup provides a comprehensive framework for managing and configuring the database account effectively. From user management to security settings, this centralized location ensures that users can efficiently customize, monitor, and optimize their database experience while adhering to regulatory compliance requirements and best practices within the financial sector.

The foregoing has described the principles, embodiments and modes of operation of the present invention. However, the invention should not be construed as being limited to the particular embodiments discussed. The above described embodiments should be regarded as illustrative rather than restrictive, and it should be appreciated that variations may be made in those embodiments by workers skilled in the art without departing from the scope of the present invention as defined by the following claims.

What is claimed is:

1. An asset management database system and devices, comprising:
 - a database system server coupled to a plurality of databases configured to allow a user access to the asset transactions and asset-related activities;
 - a remote electronic device having an asset bound tokens (ABTs) app wirelessly coupled to the database system server configured to allow a user to access the database system server;
 - a token holder records database coupled to the database system server configured to store token holder records, wherein a token holder connect ID verification process is enabled using the token holder records database when the user attempts to access the database system server to gain access;
 - a plurality of distributed databases coupled to the database system server configured to collectively manage and interlink data of four fundamental components;
 - a file management system coupled to the database system server configured to maintain and identify the four fundamental components data;
 - at least one processor coupled to the database system server configured to match the four fundamental components in the file management system;
 - at least one communication device wirelessly coupled to the database system server; and
 - a digital device app wirelessly coupled to the at least one communication device.

2. The asset management database system and devices of claim 1, wherein the four fundamental components are configured to be stored in a Token Holder Records database; Wallet Repositories database; Token Attribute Repositories database; and Asset Management Modules database.

3. The asset management database system and devices of claim 1, further comprising a transaction tracking mechanism coupled to the asset management database system configured to record, verify, and securely store every token transaction on the blockchain ledger to track and analyze performance of marketing campaigns and customer journeys.

4. The asset management database system and devices of claim 1, further comprising Token Attribute Repositories (TARs) configured to be categorized into standard, filtered, or random types of token attribute data.

5. The asset management database system and devices of claim 1, further comprising a token attribute repositories database coupled to the database system server configured for storing at least one token attribute.

6. The asset management database system and devices of claim 1, further comprising a token attribute repositories fundamental component, wherein the tokens are identified using a unique token attribute repository key and/or token attribute repository ID.

7. The asset management database system and devices of claim 1, wherein the file management system is configured to track token transactions.

8. An asset management database system and devices, comprising:

- a database system server coupled to a plurality of databases configured to allow a user access to the asset transactions and asset-related activities;
- a remote electronic device having an asset bound tokens (ABTs) app wirelessly coupled to the database system server configured to allow a user to access the database system server;
- a token holder records database coupled to the database system server configured to store token holder records, wherein a token holder connect ID verification process is enabled using the token holder records database when the user attempts to access the database system server to gain access;
- an alert manager device coupled to the asset management database system configured to allow administrators to designate recipients for critical system alerts in the event of system errors or issues, notifications are sent to specified email addresses, providing insights into the problem's nature;
- a plurality of distributed databases coupled to the database system server configured to collectively manage and interlink data of four fundamental components;
- a file management system coupled to the database system server configured to maintain and identify the four fundamental components data;
- wherein the file management system is configured to track token transactions;
- at least one processor coupled to the database system server configured to identify and match the four fundamental components in the file management system;
- at least one communication device wirelessly coupled to the database system server; and
- a digital device app wirelessly coupled to at least one communication device.

9. The asset management database system and devices of claim 8, wherein the four fundamental components are configured to be stored in a Token Holder Records database;

55

Wallet Repositories database; Token Attribute Repositories database; and Asset Management Modules database.

10. The asset management database system and devices of claim 8, further comprising a transaction tracking mechanism coupled to the asset management database system configured to record, verify, and securely store every token transaction on the blockchain ledger to track and analyze performance of marketing campaigns and customer journeys.

11. The asset management database system and devices of claim 8, further comprising Token Attribute Repositories (TARs) configured to be categorized into standard, filtered, or random types to allow for organization of token attribute data.

12. The asset management database system and devices of claim 8, further comprising a token attribute repositories database coupled to the database system server configured for storing at least one token attribute repository used to access attributes associated with tokens.

13. The asset management database system and devices of claim 8, wherein the tokens are identified using a token attribute repository ID, enabling structured management of token-related data.

14. The asset management database system and devices of claim 8, further comprising a token attribute repositories fundamental component, wherein the tokens are identified using a unique token attribute repository key.

15. An asset management database system and devices, comprising:

a database system server coupled to a plurality of databases configured to allow a user access to the asset transactions and asset-related activities;

a remote electronic device having an asset bound tokens (ABTs) app wirelessly coupled to the database system server configured to allow a user to access the database system server;

a token holder records database coupled to the database system server configured to store token holder records, wherein a token holder connect ID verification process is enabled using the token holder records database when the user attempts to access the database system server to gain access;

56

a plurality of distributed databases coupled to the database system server configured to interlink data of four fundamental components;

wherein the plurality of distributed databases include the four fundamental components data stored in a Token Holder Records database; Wallet Repositories database; Token Attribute Repositories database; and Asset Management Modules database;

a plurality of file integration automations coupled to the asset management database system configured to receive, process, and import large volumes of external data files into the database;

a file management system coupled to the database system server configured to maintain the four fundamental components data;

wherein the file management system is configured to track token management and transactions;

at least one processor coupled to the database system server configured to identify the four fundamental components with the plurality of distributed databases data;

at least one communication device wirelessly coupled to the database system server; and

a digital device app wirelessly coupled to the at least one communication device.

16. The asset management database system and devices of claim 15, further comprising a user device having the digital device app configured to display a status and user account owner staked value assets.

17. The asset management database system and devices of claim 15, further comprising Token Attribute Repositories (TARs) configured to be categorize token attribute data.

18. The asset management database system and devices of claim 15, further comprising a token attribute repositories database coupled to the database system server configured to organize token data.

19. The asset management database system and devices of claim 15, further comprising enabling structured management of token-related data.

20. The asset management database system and devices of claim 15, wherein the asset management modules represented by Asset Bound Tokens to facilitate transactions and asset-related activities.
