IMAGE ENCODING/DECODING METHOD, RECORDING MEDIUM FOR STORING BITSTREAM AND METHOD FOR TRANSMITTING BITSTREAM

Abstract

An image decoding method performed by an image decoding apparatus comprises: acquiring a neural-network post-filter characteristics (NNPFC) SEI message and a neural-network post-filter activation (NNPFA) SEI message; based on the NNPFC SEI message, determining at least one neural network which may be used as a neural-network post-processing filter; and based on the NNPFA SEI message, determining whether to activate a target neural-network post-processing filter that may be applied to the current picture, wherein the NNPFA SEI message includes target identification information and target basic flag information of the target neural-network post-processing filter, the target neural-network post-processing filter is determined based on the target identification information and the target basic flag information, and based on that the target basic flag information does not indicate that the target neural-network post-processing filter is a basic neural-network post-processing filter, at least one NNPFC SEI message is present before the NNPFA SEI in decoding order.

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS [0001] This application is a Bypass Continuation Application of International Application No. PCT/KR2024/009606, filed on Jul. 5, 2024, which claims priority from U.S. Application No. 63/525,151, filed on Jul. 5, 2023, the disclosures of which are incorporated by reference in their entirety.

BACKGROUND

- Field
[0002] The present disclosure relates to an image decoding method, an image encoding method, and a method of transmitting a bitstream, and to a method of determining whether to activate a neural network post filter.
- Description of the Related Art
[0003] Recently, demand for high-resolution and high-quality images such as high definition (HD) images and ultra high definition (UHD) images is increasing in various fields. As resolution and quality of image data are improved, the amount of transmitted information or bits relatively increases as compared to existing image data. An increase in the amount of transmitted information or

bits causes an increase in transmission cost and storage cost.

[0004] Accordingly, there is a need for high-efficient image compression technology for effectively transmitting, storing and reproducing information on high-resolution and high-quality images.

SUMMARY

[0005] The present disclosure is directed to providing an image encoding/decoding method and apparatus with improved encoding/decoding efficiency.

[0006] The present disclosure is also directed to providing a method of clearly determining a filter to be activated between a base filter and an updated filter.

[0007] The present disclosure is also directed to providing a method of preventing occurrence of a situation where it is unclear whether to activate a base filter or an updated filter.

[0008] The present disclosure is also directed to providing a non-transitory computer-readable recording medium for storing a bitstream generated using an image encoding method according to the present disclosure.

[0009] The present disclosure is also directed to providing a non-transitory computer-readable recording medium for storing a bitstream that is received and decoded by an image decoding apparatus according to the present disclosure and used for image reconstruction.

[0010] The present disclosure is also directed to providing a method of transmitting a bitstream generated using an image encoding method according to the present disclosure.

[0011] Technical objects of the present disclosure are not limited to those described above, and other technical objects that have not been described above will be clearly understood by those skilled in the technical field to which the present disclosure pertains from the following description.

[0012] An image decoding method performed by an image decoding apparatus according to one aspect of the present disclosure may include obtaining a neural-network post-filter characteristics (NNPFC) supplemental enhancement information (SEI) message and a neural-network post-filter activation (NNPFA) SEI message; determining at least one neural-network to be used as a neural-network post-filter (NNPF) based on the NNPFC SEI message; and determining whether activating a target NNPF to be applied to a current picture or not based on the NNPFA SEI message, wherein the NNPFA SEI message includes target identification information and target base flag information, wherein the target NNPF is determined based on the target identification information and the target base flag information, wherein based on the target base flag information not indicating that the target NNPF is a base NNPF, there is at least one NNPFC SEI message, that precedes the NNPFA SEI message in decoding order, with identification information equal to the target identification information and base flag information having a value equal to a value of the target base flag information.

[0013] An image encoding method performed by an image encoding apparatus according to one aspect of the present disclosure may include encoding at least one neural-network that can be used as a post-processing filter into a neural-network post-filter characteristics (NNPFC) SEI message; and encoding whether a target NNPF that can be applied to the current picture is activated into a neural-network post-filter activation (NNPFA) SEI message, wherein the NNPFA SEI message includes target identification information and target base flag information, wherein based on the target base flag information not indicating that the target NNPF is a base NNPF, there is at least one NNPFC SEI message, that precedes the NNPFA SEI message in decoding order, with identification information equal to the target identification information and base flag information having a value equal to a value of the target base flag information.

[0014] A computer-readable digital storage medium according to one aspect of the present disclosure may store bitstream generated by the image encoding method or the image encoding apparatus.

[0015] A transmitting method according to one aspect of the present disclosure may transmit bitstream generated by the image encoding method or the image encoding apparatus.

[0016] The features of the present disclosure briefly summarized above are merely illustrative aspects of the detailed description of the present disclosure and do not limit the scope of the present disclosure.

[0017] According to the present disclosure, it is possible to provide an image encoding/decoding method and apparatus with improved encoding/decoding efficiency.

[0018] According to the present disclosure, it is also possible to clarify an applied neural-network post-filter among neural-network post-filters of several preceding neural-network post-filter characteristic (NNPFC) supplemental enhancement information (SEI) messages.

[0019] According to the present disclosure, it is also possible to provide a non-transitory computer-readable recording medium for storing a bitstream generated using an image encoding method according to the present disclosure.

[0020] According to the present disclosure, it is also possible to provide a non-transitory computer-readable recording medium for storing a bitstream that is received and decoded by an image decoding apparatus according to the present disclosure and used for image reconstruction.

[0021] According to the present disclosure, it is also possible to provide a method of transmitting a bitstream generated using an image encoding method.

[0022] Effects of the present disclosure are not limited to those described above, and other effects that have not been described above will be clearly understood by those skilled in the technical field to which the present disclosure pertains from the following description.

Description

BRIEF DESCRIPTION OF DRAWINGS

[0023] FIG. 1 is a view schematically showing a video coding system to which an embodiment of the present disclosure is applicable.

[0024] FIG. 2 is a diagram schematically illustrating an image encoding device to which an embodiment according to the present disclosure can be applied.

[0025] FIG. 3 is a schematic diagram illustrating an image decoding device to which an embodiment according to the present disclosure can be applied.

[0026] FIG. 4 exemplarily shows a hierarchical structure for coded video/image to which an embodiment according to the present disclosure can be applied.

[0027] FIG. 5 is a diagram illustrating an interleaved method for deriving a luma channel.

[0028] FIG. 6 is a diagram illustrating a problematic situation that may occur when a target NNPF to be activated is identified on the basis of a neural-network post-filter activation (NNPFA) SEI message.

[0029] FIG. 7 is an example of a case to which an embodiment of the present invention is applied.

[0030] FIG. 8 is another example of a case to which an embodiment of the present invention is applied and

[0031] FIG. 9 is an example of an image encoding method to which embodiments of the present disclosure are applicable.

[0032] FIG. 10 is an example of an image decoding method to which embodiments of the present disclosure are applicable.

[0033] FIG. 11 shows a process of determining a target NNPF according to an embodiment of the present disclosure.

[0034] FIG. 12 shows a process of determining a target NNPF according to an embodiment of the present disclosure.

[0035] FIG. 13 is a diagram exemplifying a content streaming system to which an embodiment according to the present disclosure can be applied.

DETAILED DESCRIPTION

[0036] Hereinafter, the embodiments of the present disclosure will be described in detail with reference to the accompanying drawings so as to be easily implemented by those skilled in the art. However, the present disclosure may be implemented in various different forms, and is not limited to the embodiments described herein.

[0037] In describing the present disclosure, if it is determined that the detailed description of a related known function or construction renders the scope of the present disclosure unnecessarily ambiguous, the detailed description thereof will be omitted. In the drawings, parts not related to the description of the present disclosure are omitted, and similar reference numerals are attached to similar parts.

[0038] In the present disclosure, when a component is “connected”, “coupled” or “linked” to another component, it may include not only a direct connection relationship but also an indirect connection relationship in which an intervening component is present. In addition, when a component “includes” or “has” other components, it means that other components may be further included, rather than excluding other components unless otherwise stated.

[0039] In the present disclosure, the terms first, second, etc. may be used only for the purpose of distinguishing one component from other components, and do not limit the order or importance of the components unless otherwise stated. Accordingly, within the scope of the present disclosure, a first component in one embodiment may be referred to as a second component in another embodiment, and similarly, a second component in one embodiment may be referred to as a first component in another embodiment.

[0040] In the present disclosure, components that are distinguished from each other are intended to clearly describe each feature, and do not mean that the components are necessarily separated. That is, a plurality of components may be integrated and implemented in one hardware or software unit, or one component may be distributed and implemented in a plurality of hardware or software units. Therefore, even if not stated otherwise, such embodiments in which the components are integrated or the component is distributed are also included in the scope of the present disclosure.

[0041] In the present disclosure, the components described in various embodiments do not necessarily mean essential components, and some components may be optional components. Accordingly, an embodiment consisting of a subset of components described in an embodiment is also included in the scope of the present disclosure. In addition, embodiments including other components in addition to components described in the various embodiments are included in the scope of the present disclosure.

[0042] The present disclosure relates to encoding and decoding of an image, and terms used in the present disclosure may have a general meaning commonly used in the technical field, to which the present disclosure belongs, unless newly defined in the present disclosure.

[0043] The present disclosure presents various embodiments of video/image coding, and unless otherwise stated, the embodiments may be performed in combination with each other.

[0044] The terms used in the present disclosure may have their usual meanings in the technical field to which the present disclosure belongs, unless newly defined in the present disclosure.

[0045] In the present disclosure, a “picture” generally means a unit representing one image of a specific time period, and a slice/tile is a coding unit constituting a part of a picture, and one picture may be composed of one or more slices/tiles. In addition, a slice/tile may include one or more CTUs (coding tree units). One picture may be composed of one or more tile groups. One tile group may include one or more tiles. A brick may represent a rectangular area of CTU rows of tiles in a picture. In this document, tile group and slice may be used interchangeably.

[0046] For example, in this document, a tile group/tile group header may be called a slice/slice header.

[0047] In the present disclosure, a “pixel” or a “pel” may mean a smallest unit constituting one picture (or image). In addition, “sample” may be used as a term corresponding to a pixel. A sample may generally represent a pixel or a value of a pixel, and may represent only a pixel/pixel value of a luma component or only a pixel/pixel value of a chroma component.

[0048] In the present disclosure, a “unit” may represent a basic unit of image processing. The unit may include at least one of a specific region of the picture and information related to the region. One unit may include one luma block and two chroma (e.g., Cb, Cr) blocks. The unit may be used interchangeably with terms such as “sample array”, “block” or “area” in some cases. In a general case, an M×N block may include samples (or sample arrays) or a set (or array) of transform coefficients of M columns and N rows.

[0049] In the present disclosure, “current block” may mean one of “current coding block”, “current coding unit”, “coding target block”, “decoding target block” or “processing target block”. When prediction is performed, “current block” may mean “current prediction block” or “prediction target block”. When transform (inverse transform)/quantization (dequantization) is performed, “current block” may mean “current transform block” or “transform target block”. When filtering is performed, “current block” may mean “filtering target block”.

[0050] In addition, in the present disclosure, a “current block” may mean a block including both a luma component block and a chroma component block or “a luma block of a current block” unless explicitly stated as a chroma block. The chroma component block of the current block may be expressed by including an explicit description of a chroma component block such as “chroma block” or “current chroma block”.

[0051] In the present disclosure, the term “/” and “,” should be interpreted to indicate “and/or”. For instance, the expression “A/B”

and “A, B” may mean “A and/or B.” Further, “A/B/C” and “A, B, C” may mean “at least one of A, B, and/or C.”

[0052] In the present disclosure, the term “or” should be interpreted to indicate “and/or.” For instance, the expression “A or B” may comprise 1) only “A”, 2) only “B”, and/or 3) both “A and B”. In other words, in the present disclosure, the term “or” should be interpreted to indicate “additionally or alternatively.”

Overview of Video Coding System

[0053] FIG. 1 is a view schematically showing a video coding system to which an embodiment of the present disclosure is applicable.

[0054] The video coding system according to an embodiment may include an encoding device **10** and a decoding device **20**. The encoding device **10** may deliver encoded video and/or image information or data to the decoding device **20** in the form of a file or streaming via a digital storage medium or network.

[0055] The encoding device **10** according to an embodiment may include a video source generator **11**, an encoder **12** and a transmitter **13**. The decoding device **20** according to an embodiment may include a receiver **21**, a decoder **22** and a renderer **23**. The encoder **12** may be called a video/image encoding apparatus, and the decoder **22** may be called a video/image decoding apparatus. The transmitter **13** may be included in the encoder **12**. The receiver **21** may be included in the decoder **22**. The renderer **23** may include a display and the display may be configured as a separate device or an external component.

[0056] The video source generator **11** may obtain a video/image through a process of capturing, synthesizing or generating the video/image. The video source generator **11** may include a video/image capture device and/or a video/image generating device. The video/image capture device may include, for example, one or more cameras, video/image archives including previously captured video/images, and the like. The video/image generating device may include, for example, computers, tablets and smartphones, and may (electronically) generate video/images. For example, a virtual video/image may be generated through a computer or the like. In this case, the video/image capturing process may be replaced by a process of generating related data.

[0057] The encoder **12** may encode an input video/image. The encoder **12** may perform a series of procedures such as prediction, transform, and quantization for compression and coding efficiency. The encoder **12** may output encoded data (encoded video/image information) in the form of a bitstream.

[0058] The transmitter **13** may transmit the encoded video/image information or data output in the form of a bitstream to the receiver **21** of the decoding device **20** through a digital storage medium or a network in the form of a file or streaming. The digital storage medium may include various storage mediums such as USB, SD, CD, DVD, Blu-ray, HDD, SSD, and the like. The transmitter **13** may include an element for generating a media file through a predetermined file format and may include an element for transmission through a broadcast/communication network. The transmitter **13** may be provided as a separate transmission device from the encoder **120**. In this case, the transmission device includes at least one processor that obtains encoded video/image information or data output in the form of a bitstream and a transmitter that delivers it in the form of a file or streaming. The receiver **21** may extract/receive the bitstream from the storage medium or network and transmit the bitstream to the decoder **22**.

[0059] The decoder **22** may decode the video/image by performing a series of procedures such as dequantization, inverse transform, and prediction corresponding to the operation of the encoder **12**.

[0060] The renderer **23** may render the decoded video/image. The rendered video/image may be displayed through the display.

Overview of the Video Encoding Device

[0061] FIG. 2 is a diagram schematically illustrating an image encoding device to which an embodiment according to the present disclosure can be applied.

[0062] Referring to FIG. 2, the encoding apparatus **200** includes an image partitioner **210**, a predictor **220**, a residual processor **230**, and an entropy encoder **240**, an adder **250**, a filter **260**, and a memory **270**. The predictor **220** may include an inter predictor **221** and an intra predictor **222**. The residual processor **230** may include a transformer **232**, a quantizer **233**, a dequantizer **234**, and an inverse transformer **235**. The residual processor **230** may further include a subtractor **231**. The adder **250** may be called a reconstructor or a reconstructed block generator. The image partitioner **210**, the predictor **220**, the residual processor **230**, the entropy encoder **240**, the adder **250**, and the filter **260** may be configured by at least one hardware component (ex. an encoder chipset or processor) according to an embodiment. In addition, the memory **270** may include a decoded picture buffer (DPB) or may be configured by a digital storage medium. The hardware component may further include the memory **270** as an internal/external component.

[0063] The image partitioner **210** may partition an input image (or a picture or a frame) input to the encoding apparatus **200** into one or more processors. For example, the processor may be called a coding unit (CU). In this case, the coding unit may be recursively partitioned according to a quad-tree binary-tree ternary-tree (QTBT TT) structure from a coding tree unit (CTU) or a largest coding unit (LCU). For example, one coding unit may be partitioned into a plurality of coding units of a deeper depth based on a quad tree structure, a binary tree structure, and/or a ternary structure. In this case, for example, the quad tree structure may be applied first and the binary tree structure and/or ternary structure may be applied later. Alternatively, the binary tree structure may be applied first. The coding procedure according to this document may be performed based on the final coding unit that is no longer partitioned. In this case, the largest coding unit may be used as the final coding unit based on coding efficiency according to image characteristics, or if necessary, the coding unit may be recursively partitioned into coding units of deeper depth and a coding unit having an optimal size may be used as the final coding unit. Here, the coding procedure may include a procedure of prediction, transform, and reconstruction, which will be described later. As another example, the processor may further include a predictor (PU) or a transform unit (TU). In this case, the predictor and the transform unit may be split or partitioned from the aforementioned final coding unit. The predictor may be a unit of sample prediction, and the transform unit may be a unit for deriving a transform coefficient and/or a unit for deriving a residual signal from the transform coefficient.

[0064] In the encoding apparatus **200**, a prediction signal (predicted block, prediction sample array) output from the inter predictor **221** or the intra predictor **222** is subtracted from an input image signal (original block, original sample array) to generate a residual signal residual block, residual sample array), and the generated residual signal is transmitted to the transformer **232**. In this case, as shown, a unit for subtracting a prediction signal (predicted block, prediction sample array) from the input image signal (original block, original sample array) in the encoder **200** may be called a subtractor **231**. The predictor may perform prediction on a block to be processed (hereinafter, referred to as a current block) and generate a predicted block including prediction samples for the current block. The predictor may determine whether intra prediction or inter prediction is applied on a current block or CU basis. As described later in the description of each prediction mode, the predictor may generate various information related to prediction, such

as prediction mode information, and transmit the generated information to the entropy encoder **240**. The information on the prediction may be encoded in the entropy encoder **240** and output in the form of a bitstream.

[0065] The intra predictor **222** may predict the current block by referring to the samples in the current picture. The referred samples may be located in the neighborhood of the current block or may be located apart according to the prediction mode. In the intra prediction, prediction modes may include a plurality of non-directional modes and a plurality of directional modes. The non-directional mode may include, for example, a DC mode and a planar mode. The directional mode may include, for example, **33** directional prediction modes or **65** directional prediction modes according to the degree of detail of the prediction direction. However, this is merely an example, more or less directional prediction modes may be used depending on a setting. The intra predictor **222** may determine the prediction mode applied to the current block by using a prediction mode applied to a neighboring block.

[0066] The inter predictor **221** may derive a predicted block for the current block based on a reference block (reference sample array) specified by a motion vector on a reference picture. Here, in order to reduce the amount of motion information transmitted in the inter prediction mode, the motion information may be predicted in units of blocks, subblocks, or samples based on correlation of motion information between the neighboring block and the current block. The motion information may include a motion vector and a reference picture index. The motion information may further include inter prediction direction (L0 prediction, L1 prediction, Bi prediction, etc.) information. In the case of inter prediction, the neighboring block may include a spatial neighboring block present in the current picture and a temporal neighboring block present in the reference picture. The reference picture including the reference block and the reference picture including the temporal neighboring block may be the same or different. The temporal neighboring block may be called a collocated reference block, a co-located CU (colCU), and the like, and the reference picture including the temporal neighboring block may be called a collocated picture (colPic). For example, the inter predictor **221** may configure a motion information candidate list based on neighboring blocks and generate information indicating which candidate is used to derive a motion vector and/or a reference picture index of the current block. Inter prediction may be performed based on various prediction modes. For example, in the case of a skip mode and a merge mode, the inter predictor **221** may use motion information of the neighboring block as motion information of the current block. In the skip mode, unlike the merge mode, the residual signal may not be transmitted. In the case of the motion vector prediction (MVP) mode, the motion vector of the neighboring block may be used as a motion vector predictor and the motion vector of the current block may be indicated by signaling a motion vector difference.

[0067] The predictor **220** may generate a prediction signal based on various prediction methods described below. For example, the predictor may not only apply intra prediction or inter prediction to predict one block but also simultaneously apply both intra prediction and inter prediction. This may be called combined inter and intra prediction (CIIP). In addition, the predictor may be based on an intra block copy (IBC) prediction mode or a palette mode for prediction of a block. The IBC prediction mode or palette mode may be used for content image/video coding of a game or the like, for example, screen content coding (SCC). The IBC basically performs prediction in the current picture but may be performed similarly to inter prediction in that a reference block is derived in the current picture. That is, the IBC may use at least one of the inter prediction techniques described in this document. The palette mode may be considered as an example of intra coding or intra prediction. When the palette mode is applied, a sample value within a picture may be signaled based on information on the palette table and the palette index.

[0068] The prediction signal generated by the predictor (including the inter predictor **221** and/or the intra predictor **222**) may be used to generate a reconstructed signal or to generate a residual signal. The subtraction unit **115** can subtract the prediction signal (predicted block, predicted sample array) output from the predictor **200** from the input image signal (original block, original sample array) to generate a residual signal (residual block, residual sample array). The generated residual signal can be transmitted to the conversion unit **232**.

[0069] The transformer **232** may generate transform coefficients by applying a transform technique to the residual signal. For example, the transform technique may include at least one of a discrete cosine transform (DCT), a discrete sine transform (DST), a karhunen-loève transform (KLT), a graph-based transform (GBT), or a conditionally non-linear transform (CNT). Here, the GBT means transform obtained from a graph when relationship information between pixels is represented by the graph. The CNT refers to transform generated based on a prediction signal generated using all previously reconstructed pixels. In addition, the transform process may be applied to square pixel blocks having the same size or may be applied to blocks having a variable size rather than square.

[0070] The quantizer **233** may quantize the transform coefficients and transmit them to the entropy encoder **240** and the entropy encoder **240** may encode the quantized signal (information on the quantized transform coefficients) and output a bitstream. The information on the quantized transform coefficients may be referred to as residual information. The quantizer **233** may rearrange block type quantized transform coefficients into a one-dimensional vector form based on a coefficient scanning order and generate information on the quantized transform coefficients based on the quantized transform coefficients in the one-dimensional vector form. Information on transform coefficients may be generated.

[0071] The entropy encoder **240** may perform various encoding methods such as, for example, exponential Golomb, context-adaptive variable length coding (CAVLC), context-adaptive binary arithmetic coding (CABAC), and the like. The entropy encoder **240** may encode information necessary for video/image reconstruction other than quantized transform coefficients (ex. values of syntax elements, etc.) together or separately. Encoded information (ex. encoded video/image information) may be transmitted or stored in units of NALs (network abstraction layer) in the form of a bitstream. The video/image information may further include information on various parameter sets such as an adaptation parameter set (APS), a picture parameter set (PPS), a sequence parameter set (SPS), or a video parameter set (VPS). In addition, the video/image information may further include general constraint information. In this document, information and/or syntax elements transmitted/signaled from the encoding apparatus to the decoding apparatus may be included in video/picture information. The video/image information may be encoded through the above-described encoding procedure and included in the bitstream.

[0072] The bitstream may be transmitted over a network or may be stored in a digital storage medium. The network may include a broadcasting network and/or a communication network, and the digital storage medium may include various storage media such as USB, SD, CD, DVD, Blu-ray, HDD, SSD, and the like. A transmitter (not shown) transmitting a signal output from the entropy encoder **240** and/or a storage unit (not shown) storing the signal may be included as internal/external element of the encoding apparatus **200**, and alternatively, the transmitter may be included in the entropy encoder **240**.

[0073] The quantized transform coefficients output from the quantizer **233** may be used to generate a prediction signal. For example, the residual signal (residual block or residual samples) may be reconstructed by applying dequantization and inverse transform to the quantized transform coefficients through the dequantizer **234** and the inverse transformer **235**.

[0074] The adder **250** adds the reconstructed residual signal to the prediction signal output from the inter predictor **221** or the intra predictor **222** to generate a reconstructed signal (reconstructed picture, reconstructed block, reconstructed sample array). If there is no residual for the block to be processed, such as a case where the skip mode is applied, the predicted block may be used as the reconstructed block. The adder **250** may be called a reconstructor or a reconstructed block generator. The generated reconstructed signal may be used for intra prediction of a next block to be processed in the current picture and may be used for inter prediction of a next picture through filtering as described below.

[0075] The filter **260** may improve subjective/objective image quality by applying filtering to the reconstructed signal. For example, the filter **260** may generate a modified reconstructed picture by applying various filtering methods to the reconstructed picture and store the modified reconstructed picture in the memory **270**, specifically, a DPB of the memory **270**. The various filtering methods may include, for example, deblocking filtering, a sample adaptive offset, an adaptive loop filter, a bilateral filter, and the like. The filter **260** may generate various information related to the filtering and transmit the generated information to the entropy encoder **240** as described later in the description of each filtering method. The information related to the filtering may be encoded by the entropy encoder **240** and output in the form of a bitstream.

[0076] The modified reconstructed picture transmitted to the memory **270** may be used as the reference picture in the inter predictor **221**. When the inter prediction is applied through the encoding apparatus, prediction mismatch between the encoding apparatus **200** and the decoding apparatus may be avoided and encoding efficiency may be improved.

[0077] The DPB of the memory **270** may store the modified reconstructed picture for use as a reference picture in the inter predictor **221**. The memory **270** may store the motion information of the block from which the motion information in the current picture is derived (or encoded) and/or the motion information of the blocks in the picture that have already been reconstructed. The stored motion information may be transmitted to the inter predictor **221** and used as the motion information of the spatial neighboring block or the motion information of the temporal neighboring block. The memory **270** may store reconstructed samples of reconstructed blocks in the current picture and may transfer the reconstructed samples to the intra predictor **222**.

Overview of Image Decoding Device

[0078] FIG. 3 is a schematic diagram illustrating an image decoding device to which an embodiment according to the present disclosure can be applied.

[0079] Referring to FIG. 3, the decoding apparatus **300** may include an entropy decoder **310**, a residual processor **320**, a predictor **330**, an adder **340**, a filter **350**, a memory **360**. The predictor **330** may include an inter predictor **331** and an intra predictor **332**. The residual processor **320** may include a dequantizer **321** and an inverse transformer **321**. The entropy decoder **310**, the residual processor **320**, the predictor **330**, the adder **340**, and the filter **350** may be configured by a hardware component (ex. a decoder chipset or a processor) according to an embodiment. In addition, the memory **360** may include a decoded picture buffer (DPB) or may be configured by a digital storage medium. The hardware component may further include the memory **360** as an internal/external component.

[0080] When a bitstream including video/image information is input, the decoding apparatus **300** may reconstruct an image corresponding to a process in which the video/image information is processed in the encoding apparatus of FIG. 2. For example, the decoding apparatus **300** may derive units/blocks based on block partition related information obtained from the bitstream. The decoding apparatus **300** may perform decoding using a processor applied in the encoding apparatus. Thus, the processor of decoding may be a coding unit, for example, and the coding unit may be partitioned according to a quad tree structure, binary tree structure and/or ternary tree structure from the coding tree unit or the largest coding unit. One or more transform units may be derived from the coding unit. The reconstructed image signal decoded and output through the decoding apparatus **300** may be reproduced through a reproducing apparatus.

[0081] The decoding apparatus **300** may receive a signal output from the encoding apparatus of FIG. 2 in the form of a bitstream, and the received signal may be decoded through the entropy decoder **310**. For example, the entropy decoder **310** may parse the bitstream to derive information (ex. video/image information) necessary for image reconstruction (or picture reconstruction). The video/image information may further include information on various parameter sets such as an adaptation parameter set (APS), a picture parameter set (PPS), a sequence parameter set (SPS), or a video parameter set (VPS). In addition, the video/image information may further include general constraint information. The decoding apparatus may further decode picture based on the information on the parameter set and/or the general constraint information. Signaled/received information and/or syntax elements described later in this document may be decoded may decode the decoding procedure and obtained from the bitstream. For example, the entropy decoder **310** decodes the information in the bitstream based on a coding method such as exponential Golomb coding, CAVLC, or CABAC, and output syntax elements required for image reconstruction and quantized values of transform coefficients for residual. More specifically, the CABAC entropy decoding method may receive a bin corresponding to each syntax element in the bitstream, determine a context model using a decoding target syntax element information, decoding information of a decoding target block or information of a symbol/bin decoded in a previous stage, and perform an arithmetic decoding on the bin by predicting a probability of occurrence of a bin according to the determined context model, and generate a symbol corresponding to the value of each syntax element. In this case, the CABAC entropy decoding method may update the context model by using the information of the decoded symbol/bin for a context model of a next symbol/bin after determining the context model. The information related to the prediction among the information decoded by the entropy decoder **310** may be provided to the predictor (the inter predictor **332** and the intra predictor **331**), and the residual value on which the entropy decoding was performed in the entropy decoder **310**, that is, the quantized transform coefficients and related parameter information, may be input to the residual processor **320**. The residual processor **320** may derive the residual signal (the residual block, the residual samples, the residual sample array). In addition, information on filtering among information decoded by the entropy decoder **310** may be provided to the filter **350**. Meanwhile, a receiver (not shown) for receiving a signal output from the encoding apparatus may be further configured as an internal/external element of the decoding apparatus **300**, or the receiver may be a component of the entropy decoder **310**.

[0082] Meanwhile, the decoding apparatus according to this document may be referred to as a video/image/picture decoding

apparatus, and the decoding apparatus may be classified into an information decoder (video/image/picture information decoder) and a sample decoder (video/image/picture sample decoder). The information decoder may include the entropy decoder **310**, and the sample decoder may include at least one of the dequantizer **321**, the inverse transformer **322**, the adder **340**, the filter **350**, the memory **360**, the inter predictor **332**, and the intra predictor **331**.

[0083] The dequantizer **321** may dequantize the quantized transform coefficients and output the transform coefficients. The dequantizer **321** may rearrange the quantized transform coefficients in the form of a two-dimensional block form. In this case, the rearrangement may be performed based on the coefficient scanning order performed in the encoding apparatus. The dequantizer **321** may perform dequantization on the quantized transform coefficients by using a quantization parameter (ex. quantization step size information) and obtain transform coefficients.

[0084] The inverse transformer **322** inversely transforms the transform coefficients to obtain a residual signal (residual block, residual sample array).

[0085] The predictor **330** may perform prediction on the current block and generate a predicted block including prediction samples for the current block. The predictor may determine whether intra prediction or inter prediction is applied to the current block based on the information on the prediction output from the entropy decoder **310** and may determine a specific intra/inter prediction mode.

[0086] The predictor **330** may generate a prediction signal based on various prediction methods (techniques) described below, which is the same as that mentioned in the description of the predictor **220** of the image encoding device **200**.

[0087] The intra predictor **332** may predict the current block by referring to the samples in the current picture. The referenced samples may be located in the neighborhood of the current block or may be located apart according to the prediction mode. In intra prediction, prediction modes may include a plurality of non-directional modes and a plurality of directional modes. The intra predictor **331** may determine the prediction mode applied to the current block by using the prediction mode applied to the neighboring block.

[0088] The inter predictor **331** may derive a predicted block for the current block based on a reference block (reference sample array) specified by a motion vector on a reference picture. In this case, in order to reduce the amount of motion information transmitted in the inter prediction mode, motion information may be predicted in units of blocks, subblocks, or samples based on correlation of motion information between the neighboring block and the current block. The motion information may include a motion vector and a reference picture index. The motion information may further include inter prediction direction (L0 prediction, L1 prediction, Bi prediction, etc.) information. In the case of inter prediction, the neighboring block may include a spatial neighboring block present in the current picture and a temporal neighboring block present in the reference picture. For example, the inter predictor **332** may configure a motion information candidate list based on neighboring blocks and derive a motion vector of the current block and/or a reference picture index based on the received candidate selection information. Inter prediction may be performed based on various prediction modes, and the information on the prediction may include information indicating a mode of inter prediction for the current block.

[0089] The adder **340** may generate a reconstructed signal (reconstructed picture, reconstructed block, reconstructed sample array) by adding the obtained residual signal to the prediction signal (predicted block, predicted sample array) output from the predictor (including the inter predictor **332** and/or the intra predictor **331**). If there is no residual for the block to be processed, such as when the skip mode is applied, the predicted block may be used as the reconstructed block. The adder **340** may be called reconstructor or a reconstructed block generator. The generated reconstructed signal may be used for intra prediction of a next block to be processed in the current picture, may be output through filtering as described below, or may be used for inter prediction of a next picture.

[0090] The filter **350** may improve subjective/objective image quality by applying filtering to the reconstructed signal. For example, the filter **350** may generate a modified reconstructed picture by applying various filtering methods to the reconstructed picture and store the modified reconstructed picture in the memory **360**, specifically, a DPB of the memory **360**. The various filtering methods may include, for example, deblocking filtering, a sample adaptive offset, an adaptive loop filter, a bilateral filter, and the like.

[0091] The (modified) reconstructed picture stored in the DPB of the memory **360** may be used as a reference picture in the inter predictor **332**. The memory **360** may store the motion information of the block from which the motion information in the current picture is derived (or decoded) and/or the motion information of the blocks in the picture that have already been reconstructed. The stored motion information may be transmitted to the inter predictor **260** so as to be utilized as the motion information of the spatial neighboring block or the motion information of the temporal neighboring block. The memory **360** may store reconstructed samples of reconstructed blocks in the current picture and transfer the reconstructed samples to the intra predictor **331**.

[0092] In the present disclosure, the embodiments described in the filter **260**, the inter predictor **221**, and the intra predictor **222** of the encoding apparatus **100** may be the same as or respectively applied to correspond to the filter **350**, the inter predictor **332**, and the intra predictor **331** of the decoding apparatus **300**. The same may also apply to the unit **332** and the intra predictor **331**.

[0093] FIG. **4** exemplarily shows a hierarchical structure for coded video/image to which an embodiment according to the present disclosure can be applied.

[0094] Referring to FIG. **4**, coded image/video is divided into a VCL (video coding layer) that handles the decoding process of the image/video and itself, a subsystem that transmits and stores the coded information, and NAL (network abstraction layer) in charge of function and present between the VCL and the subsystem.

[0095] In the VCL, VCL data including compressed image data (slice data) is generated, or a parameter set including a picture parameter set (PPS), a sequence parameter set (SPS), and a video parameter set (VPS) or a supplemental enhancement information (SEI) message additionally required for an image decoding process may be generated.

[0096] In the NAL, a NAL unit may be generated by adding header information (NAL unit header) to a raw byte sequence payload (Rbsp) generated in a VCL. In this case, the Rbsp refers to slice data, parameter set, SEI message, etc., generated in the VCL. The NAL unit header may include NAL unit type information specified according to Rbsp data included in the corresponding NAL unit.

[0097] As shown in the figure, the NAL unit may be classified into a VCL NAL unit and a Non-VCL NAL unit according to the Rbsp generated in the VCL. The VCL NAL unit may mean a NAL unit that includes information on the image (slice data) on the image, and the Non-VCL NAL unit may mean a NAL unit that includes information (parameter set or SEI message) required for decoding the image.

[0098] The above-described VCL NAL unit and Non-VCL NAL unit may be transmitted through a network by attaching header information according to the data standard of the subsystem. For example, the NAL unit may be transformed into a data format of a

predefined standard such as an H.266/VVC file format, a real-time transport protocol (RTP), a transport stream (TS), etc., and transmitted through various networks.

[0099] As described above, the NAL unit may be specified with the NAL unit type according to the RBSP data structure included in the corresponding NAL unit, and information on the NAL unit type may be stored and signaled in the NAL unit header.

[0100] For example, the NAL unit may be classified into a VCL NAL unit type and a Non-VCL NAL unit type according to whether the NAL unit includes information (slice data) about an image. The VCL NAL unit type may be classified according to the nature and type of pictures included in the VCL NAL unit, and the Non-VCL NAL unit type may be classified according to types of parameter sets.

[0101] The following is an example of the NAL unit type specified according to the type of parameter set included in the Non-VCL NAL unit type. [0102] APS (Adaptation Parameter Set) NAL unit: Type for NAL unit including APS [0103] DPS (Decoding Parameter Set) NAL unit: Type for NAL unit including DPS [0104] VPS (Video Parameter Set) NAL unit: Type for NAL unit including VPS [0105] SPS (Sequence Parameter Set) NAL unit: Type for NAL unit including SPS [0106] PPS (Picture Parameter Set) NAL unit: Type for NAL unit including PPS

[0107] The aforementioned NAL unit types may have syntax information for the NAL unit type, and the syntax information may be stored and signaled in a NAL unit header. For example, the syntax information may be `nal_unit_type`, and NAL unit types may be specified by a `nal_unit_type` value.

[0108] The slice header (slice header syntax) may include information/parameters that may be commonly applied to the slice. The APS (APS syntax) or the PPS (PPS syntax) may include information/parameters that may be commonly applied to one or more slices or pictures. The SPS (SPS syntax) may include information/parameters that may be commonly applied to one or more sequences. The VPS (VPS syntax) may include information/parameters that may be commonly applied to multiple layers. The DPS (DPS syntax) may include information/parameters that may be commonly applied to the overall video. The DPS may include information/parameters related to concatenation of a coded video sequence (CVS). High level syntax (HLS) in this document may include at least one of the APS syntax, PPS syntax, SPS syntax, VPS syntax, DPS syntax, a picture header syntax and slice header syntax.

[0109] In this document, the image/video information encoded from the encoding apparatus and signaled to the decoding apparatus in the form of a bitstream includes not only partitioning related information in a picture, intra/inter prediction information, residual information, in-loop filtering information, etc, but also information included in a slice header, information included in the picture header, information included in the APS, information included in the PPS, information included in an SPS, information included in a VPS and/or information included in a DPS.

General Post-Processing Filtering Process Using NNPFs

[0110] Input to this process is a bitstream `BitstreamToFilter`. Output of this process is a list of NNPF output pictures `ListNnpfOutputPics`. First, `BitstreamToFilter` is decoded, and the list `CroppedDecodedPictures` is set to be the list of the cropped decoded pictures in output order resulted from decoding `BitstreamToFilter`. Second, the filtering process for one picture is repeatedly invoked, in output order, for each cropped decoded picture that is in `CroppedDecodedPictures` and for which one or more NNPFs are activated. The order of the pictures in `ListNnpfOutputPics` is in output order.

[0111] Within `ListNnpfOutputPics` there shall be no more than one picture pertaining to any particular output time instance. When for any particular picture in `CroppedDecodedPictures` there are multiple NNPFs activated and only one the NNPFs is allowed to be chosen to be applied although any of the NNPFs may be chosen, the above constraint shall apply regardless of which NNPF is chosen to be applied to the particular picture.

[0112] The filtering process specified applies to each cropped decoded picture, referred to as the current picture, that is in `CroppedDecodedPictures` and for which one or more NNPFs are activated. When applying an NNPF to the current picture, the filtered and/or interpolated pictures are generated by the NNPF by applying the NNPF process specified in the semantics of the NNPF SEI message, in a patch-wise manner, to the current picture.

[0113] When applying an NNPF to the current picture, the order of the pictures generated by the NNPF by applying the NNPF process being stored into the output tensor of the NNPF is in output order. When the applied NNPF is the last NNPF that is applied to the current picture, the pictures generated by the NNPF and output by the NNPF process are included into `ListNnpfOutputPics`, in the same order as when the pictures are stored into the output tensor of the NNPF.

Neural-Network Post-Filter Characteristics SEI Message (NNPFC)

[0114] The combinations in Tables 1 to 3 represent the NNPFC syntax structure.

```

[0115] The NNPFC syntax structures of Tables 1 to 3 can be signaled in the form of a supplemental enhancement information (SEI) message. An SEI message signaling the NNPFC syntax structures of Tables 1 to 3 can be referred to as an NNPFC SEI message.

[0116] The neural-network post-filter characteristics (NNPFC) SEI message specifies a neural network that may be used as a post-processing filter. The use of specified neural-network post-processing filters (NNPFs) for specific pictures is indicated with neural-network post-filter activation (NNPFA) SEI messages.

[0117] Use of this SEI message requires the definition of the following variables:

[0118] Input picture width and height in units of luma samples, denoted herein by CroppedWidth and CroppedHeight, respectively.

[0119] Luma sample array CroppedYPic[idx] and chroma sample arrays CroppedCbPic[idx] and CroppedCrPic[idx], when present, of the input pictures with index idx in the range of 0 to numInputPics-1, inclusive, that are used as input for the NNPF.

[0120] Bit depth BitDepthY for the luma sample array of the input pictures.

[0121] Bit depth BitDepthC for the chroma sample arrays, if any, of the input pictures.

[0122] A chroma format indicator, denoted herein by ChromaFormatIdc.

[0123] When nnpfc_auxiliary_inp_idc is equal to 1, a filtering strength control value array

[0124] StrengthControlVal [idx] that shall contain real numbers in the range of 0 to 1, inclusive, of the input pictures with index idx in the range of 0 to numInputPics-1, inclusive.

[0125] Input picture with index 0 corresponds to the picture for which the NNPF defined by this NNPFC SEI message is activated by an NNPFA SEI message. Input picture with index i in the range of 1 to numInputPics-1, inclusive, precedes the input picture with index i-1 in output order.

[0126] The variables Sub WidthC and SubHeightC are derived from ChromaFormatIdc. More than one NNPFC SEI message can be present for the same picture. When more than one NNPFC SEI message with different values of nnpfc_id is present or activated for the same picture, they can have the same or different values of nnpfc_purpose and nnpfc_mode_idc.

[0127] The nnpfc_purpose indicates the purpose of the NNPF as specified in Table 3, where (nnpfc_purpose & bitMask) not equal to 0 indicates that the NNPF has the purpose associated with the bitMask value in Table 3. When nnpfc_purpose is greater than 0 and (nnpfc_purpose & bitMask) is equal to 0, the purpose associated with the bitMask value is not applicable to the NNPF. When nnpfc_purpose is equal to 0, the NNPF may be used as determined by the application.

[0128] The value of nnpfc_purpose shall be in the range of 0 to 63, inclusive, in bitstreams conforming to this edition of this document. Values of 64 to 65 535, inclusive, for nnpfc_purpose are reserved for future use by ITU-T|ISO/IEC and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPFC SEI messages with nnpfc_purpose in the range of 64 to 65 535, inclusive.

TABLE-US-00004 TABLE 4 bitMask Interpretation 0x01 General visual quality improvement 0x02 Chroma upsampling (from the 4:2:0 chroma format to the 4:2:2 or 4:4:4 chroma format, or from the 4:2:2 chroma format to the 4:4:4 chroma format) 0x04 Resolution resampling (increasing or decreasing the width or height) 0x08 Picture rate upsampling 0x10 Bit depth upsampling (increasing the luma bit depth or the chroma bit depth) 0x20 Colourization

[0129] The variables chromaUpsamplingFlag, resolutionResamplingFlag, pictureRateUpsamplingFlag, bitDepthUpsamplingFlag, and colourizationFlag, specifying whether nnpfc_purpose indicates the purpose of the NNPF to include chroma upsampling, resolution resampling, picture rate upsampling, bit depth upsampling, and colourization, respectively, are derived as follows:

```

TABLE-US-00005 TABLE 5 chromaUpsamplingFlag = ( ( nnpfc_purpose & 0x02 ) > 0 ) ? 1 : 0 resolutionResamplingFlag = ( (
nnpfc_purpose & 0x04 ) > 0 ) ? 1 : 0 pictureRateUpsamplingFlag = ( ( nnpfc_purpose & 0x08 ) > 0 ) ? 1 : 0 bitDepthUpsamplingFlag
= ( ( nnpfc_purpose & 0x10 ) > 0 ) ? 1 : 0 colourizationFlag = ( ( nnpfc_purpose & 0x20 ) > 0 ) ? 1 : 0

```

[0130] When a reserved value of nnpfc_purpose is taken into use in the future, the syntax of this SEI message could be extended with syntax elements whose presence is conditioned by nnpfc_purpose being equal to that value.

[0131] When ChromaFormatIdc is equal to 3, chromaUpsamplingFlag shall be equal to 0.

[0132] When ChromaFormatIdc or chromaUpsamplingFlag is not equal to 0, colourizationFlag shall be equal to 0.

[0133] When pictureRateUpsamplingFlag is equal to 1 and the input picture with index 0 is associated with a frame packing arrangement SEI message with fp_arrangement_type equal to 5, all input pictures are associated with a frame packing arrangement SEI message with fp_arrangement_type equal to 5 and the same value of fp_current_frame_is_frame0_flag.

[0134] The nnpfc_id contains an identifying number that may be used to identify an NNPF. The value of nnpfc_id shall be in the range of 0 to 2.sup.32-2, inclusive. Values of nnpfc_id from 256 to 511, inclusive, and from 2.sup.31 to 2.sup.32-2, inclusive, are reserved for future use by ITU-T|ISO/IEC. Decoders conforming to this edition of this document encountering an NNPFC SEI message with nnpfc_id in the range of 256 to 511, inclusive, or in the range of 2.sup.31 to 2.sup.32-2, inclusive, shall ignore the SEI message.

[0135] When an NNPFC SEI message is the first NNPFC SEI message, in decoding order, that has a particular nnpfc_id value within the current CLVS, the following applies: [0136] This SEI message specifies a base NNPF. [0137] This SEI message pertains to the current decoded picture and all subsequent decoded pictures of the current layer, in output order, until the end of the current CLVS.

[0138] The `nnpfc_base_flag` equal to 1 specifies that the SEI message specifies the base NNPF. `nnpfc_base_flag` equal to 0 specifies that the SEI message specifies an update relative to the base NNPF.

[0139] The following constraints apply to the value of `nnpfc_base_flag`: [0140] When an NNPF SEI message is the first NNPF SEI message, in decoding order, that has a particular `nnpfc_id` value within the current CLVS, the value of `nnpfc_base_flag` shall be equal to 1. [0141] When an NNPF SEI message `nnpfcB` is not the first NNPF SEI message, in decoding order, that has a particular `nnpfc_id` value within the current CLVS and the value of `nnpfc_base_flag` is equal to 1, the NNPF SEI message shall be a repetition of the first NNPF SEI message `nnpfcA` with the same `nnpfc_id` value, in decoding order, i.e., the payload content of `nnpfcB` shall be the same as that of `nnpfcA`.

[0142] When `nnpfc_base_flag` is equal to 0, the following applies: [0143] This SEI message defines an update relative to the preceding base NNPF in decoding order with the same `nnpfc_id` value. Updates are not cumulative but rather each update is applied on the base NNPF, which is the NNPF specified by the first NNPF SEI message, in decoding order, that has a particular `nnpfc_id` value within the current CLVS. The NNPF defined by this SEI message is obtained by applying the update defined by this SEI message relative to the base NNPF with the same `nnpfc_id` value. [0144] This SEI message pertains to the current decoded picture and all subsequent decoded pictures of the current layer, in output order, until the end of the current CLVS or up to but excluding the decoded picture that follows the current decoded picture in output order within the current CLVS and is associated with a subsequent NNPF SEI message, in decoding order, having `nnpfc_base_flag` equal to 0 and that particular `nnpfc_id` value within the current CLVS, whichever is earlier.

[0145] The `nnpfc_mode_idc` equal to 0 indicates that this SEI message contains an ISO/IEC 15938-17 bitstream that specifies a base NNPF (when `nnpfc_base_flag` is equal to 1) or is an update relative to the base NNPF with the same `nnpfc_id` value (when `nnpfc_base_flag` is equal to 0).

[0146] When `nnpfc_base_flag` is equal to 1, `nnpfc_mode_idc` equal to 1 specifies that the base NNPF associated with the `nnpfc_id` value is a neural network identified by the URI indicated by `nnpfc_uri` with the format identified by the tag URI `nnpfc_tag_uri`. When `nnpfc_base_flag` is equal to 0, `nnpfc_mode_idc` equal to 1 specifies that an update relative to the base NNPF with the same `nnpfc_id` value is defined by the URI indicated by `nnpfc_uri` with the format identified by the tag URI `nnpfc_tag_uri`.

[0147] The value of `nnpfc_mode_idc` shall be in the range of 0 to 1, inclusive, in bitstreams conforming to this edition of this document. Values of 2 to 255, inclusive, for `nnpfc_mode_idc` are reserved for future and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPF SEI messages with `nnpfc_mode_idc` in the range of 2 to 255, inclusive. Values of `nnpfc_mode_idc` greater than 255 shall not be present in bitstreams conforming to this edition of this document and are not reserved for future use.

[0148] The `nnpfc_reserved_zero_bit_a` shall be equal to 0 in bitstreams conforming to this edition of this document. Decoders shall ignore NNPF SEI messages in which `nnpfc_reserved_zero_bit_a` is not equal to 0.

[0149] The `nnpfc_tag_uri` contains a tag URI with syntax and semantics as specified in IETF RFC 4151 identifying the format and associated information about the neural network used as a base NNPF or an update relative to the base NNPF with the same `nnpfc_id` value specified by `nnpfc_uri`.

[0150] The `nnpfc_tag_uri` enables uniquely identifying the format of neural network data specified by `nnpfc_uri` without needing a central registration authority.

[0151] The `nnpfc_tag_uri` equal to “tag:iso.org,2023:15938-17” indicates that the neural network data identified by `nnpfc_uri` conforms to ISO/IEC 15938-17.

[0152] The `nnpfc_uri` contains a URI with syntax and semantics as specified in IETF Internet Standard 66 identifying the neural network used as a base NNPF or an update relative to the base NNPF with the same `nnpfc_id` value.

[0153] The `nnpfc_property_present_flag` equal to 1 specifies that syntax elements related to the filter purpose, input formatting, output formatting, and complexity are present. `nnpfc_property_present_flag` equal to 0 specifies that no syntax elements related to the filter purpose, input formatting, output formatting, and complexity are present.

[0154] When `nnpfc_base_flag` is equal to 1, `nnpfc_property_present_flag` shall be equal to 1.

[0155] When `nnpfc_property_present_flag` is equal to 0, the values of all syntax elements that may be present only when `nnpfc_property_present_flag` is equal to 1 are inferred to be equal to their corresponding syntax elements, respectively, in the NNPF SEI message that contains the base NNPF for which this SEI message provides an update.

[0156] When an NNPF SEI message `nnpfcCurr` is not the first NNPF SEI message, in decoding order, that has a particular `nnpfc_id` value within the current CLVS, is not a repetition of the first NNPF SEI message with that particular `nnpfc_id` (i.e., the value of `nnpfc_base_flag` is equal to 0), and the value of `nnpfc_property_present_flag` is equal to 1, the following constraints apply:

[0157] The value of `nnpfc_purpose` in the NNPF SEI message shall be the same as the value of `nnpfc_purpose` in the first NNPF SEI message, in decoding order, that has that particular `nnpfc_id` value within the current CLVS. [0158] The values of syntax elements following `nnpfc_property_present_flag` and preceding `nnpfc_complexity_info_present_flag`, in decoding order, in the NNPF SEI message shall be the same as the values of corresponding syntax elements in the first NNPF SEI message, in decoding order, that has that particular `nnpfc_id` value within the current CLVS. [0159] Either `nnpfc_complexity_info_present_flag` shall be equal to 0 or both `nnpfc_complexity_info_present_flag` shall be equal to 1 in the first NNPF SEI message, in decoding order, that has that particular `nnpfc_id` value within the current CLVS (denoted as `nnpfcBase` below) and all the following apply: [0160] The `nnpfc_parameter_type_idc` in `nnpfcCurr` shall be equal to `nnpfc_parameter_type_idc` in `nnpfcBase`. [0161] The `nnpfc_log2_parameter_bit_length_minus3` in `nnpfcCurr`, when present, shall be less than or equal to `nnpfc_log2_parameter_bit_length_minus3` in `nnpfcBase`. [0162] If `nnpfc_num_parameters_idc` in `nnpfcBase` is equal to 0, `nnpfc_num_parameters_idc` in `nnpfcCurr` shall be equal to 0. [0163] Otherwise (`nnpfc_num_parameters_idc` in `nnpfcBase` is greater than 0), `nnpfc_num_parameters_idc` in `nnpfcCurr` shall be greater than 0 and less than or equal to `nnpfc_num_parameters_idc` in `nnpfcBase`. [0164] If `nnpfc_num_kmac_operations_idc` in `nnpfcBase` is equal to 0, `nnpfc_num_kmac_operations_idc` in `nnpfcCurr` shall be equal to 0. [0165] Otherwise (`nnpfc_num_kmac_operations_idc` in `nnpfcBase` is greater than 0), `nnpfc_num_kmac_operations_idc` in `nnpfcCurr` shall be greater than 0 and less than or equal to `nnpfc_num_kmac_operations_idc` in `nnpfcBase`. [0166] If `nnpfc_total_kilobyte_size` in `nnpfcBase` is equal to 0, `nnpfc_total_kilobyte_size` in `nnpfcCurr` shall be equal to 0. [0167] Otherwise (`nnpfc_total_kilobyte_size` in `nnpfcBase` is greater than 0), `nnpfc_total_kilobyte_size` in `nnpfcCurr` shall be greater

than 0 and less than or equal to $\text{nnpfc_total_kilobyte_size}$ in nnpfcBase .

[0168] The $\text{nnpfc_num_input_pics_minus1}$ plus 1 specifies the number of pictures used as input for the NNPF. The value of $\text{nnpfc_num_input_pics_minus1}$ shall be in the range of 0 to 63, inclusive. When $\text{pictureRateUpsamplingFlag}$ is equal to 1, the value of $\text{nnpfc_num_input_pics_minus1}$ shall be greater than 0.

[0169] The variable numInputPics , specifying the number of pictures used as input for the NNPF, is derived as follows:

[00001] $\text{numInputPics} = \text{nnpfc_num_input_pics_minus1} + 1$ [Equation1]

[0170] The $\text{nnpfc_input_pic_output_flag}[i]$ equal to 1 indicates that for the i -th input picture the NNPF generates a corresponding output picture. $\text{nnpfc_input_pic_output_flag}[i]$ equal to 0 indicates that for the i -th input picture the NNPF does not generate a corresponding output picture. When $\text{nnpfc_num_input_pics_minus1}$ is equal to 0, $\text{nnpfc_input_pic_output_flag}[0]$ is inferred to be equal to 1. When $\text{pictureRateUpsamplingFlag}$ is equal to 0 and $\text{nnpfc_num_input_pics_minus1}$ is greater than 0, $\text{nnpfc_input_pic_output_flag}[i]$ shall be equal to 1 for at least one value of i in the range of 0 to $\text{nnpfc_num_input_pics_minus1}$, inclusive.

[0171] The $\text{nnpfc_absent_input_pic_zero_flag}$ equal to 1 indicates that the NNPF expects an input picture that is not present in the bitstream to be represented by sample arrays with sample values equal to 0. $\text{nnpfc_absent_input_pic_flag}$ equal to 0 indicates that the NNPF expects an input picture that is not present in the bitstream to be represented by the closest input picture in output order within the bitstream. $\text{nnpfc_out_sub_c_flag}$ specifies the values of the variables outSubWidthC and outSubHeightC when $\text{chromaUpsamplingFlag}$ is equal to 1. $\text{nnpfc_out_sub_c_flag}$ equal to 1 specifies that outSubWidthC is equal to 1 and outSubHeightC is equal to 1. $\text{nnpfc_out_sub_c_flag}$ equal to 0 specifies that outSubWidthC is equal to 2 and outSubHeightC is equal to 1. When ChromaFormatIdc is equal to 2 and $\text{nnpfc_out_sub_c_flag}$ is present, the value of $\text{nnpfc_out_sub_c_flag}$ shall be equal to 1.

[0172] The $\text{nnpfc_out_colour_format_idc}$, when colourizationFlag is equal to 1, specifies the colour format of the NNPF output and consequently the values of the variables outSubWidthC and outSubHeightC . $\text{nnpfc_out_colour_format_idc}$ equal to 1 specifies that the colour format of the NNPF output is the 4:2:0 format and outSubWidthC and outSubHeightC are both equal to 2. $\text{nnpfc_out_colour_format_idc}$ equal to 2 specifies that the colour format of the NNPF output is the 4:2:2 format and outSubWidthC is equal to 2 and outSubHeightC is equal to 1. $\text{nnpfc_out_colour_format_idc}$ equal to 3 specifies that the colour format of the NNPF output is the 4:4:4 format and outSubWidthC and outSubHeightC are both equal to 1. The value of $\text{nnpfc_out_colour_format_idc}$ shall not be equal to 0.

[0173] When $\text{chromaUpsamplingFlag}$ and colourizationFlag are both equal to 0, outSubWidthC and outSubHeightC are inferred to be equal to SubWidthC and SubHeightC , respectively. The $\text{nnpfc_pic_width_num_minus1}$ plus 1 and $\text{nnpfc_pic_width_denom_minus1}$ plus 1 specify the numerator and denominator, respectively, for the resampling ratio of the NNPF output picture width relative to CroppedWidth . The value of $(\text{nnpfc_pic_width_num_minus1} + 1) \div (\text{nnpfc_pic_width_denom_minus1} + 1)$ shall be in the range of $1 \div 16$ to 16, inclusive. When $\text{nnpfc_pic_width_num_minus1}$ and $\text{nnpfc_pic_width_denom_minus1}$ are not present, the values of $\text{nnpfc_pic_width_num_minus1}$ and $\text{nnpfc_pic_width_denom_minus1}$ are both inferred to be equal to 0.

[0174] The variable $\text{nnpfcOutputPicWidth}$, representing the width of the luma sample arrays of the picture(s) resulting from applying the NNPF identified by nnpfc_id to the input picture(s), is derived as follows:

[00002]

$\text{nnpfcOutputPicWidth} = \text{Ceil}(\text{CroppedWidth} * (\text{nnpfc_pic_width_num_minus1} + 1) \div (\text{nnpfc_pic_width_denom_minus1} + 1))$ [Equation2]

[0175] It is a requirement of bitstream conformance that the value of $\text{nnpfcOutputPicHeight} \% \text{outSubHeightC}$ shall be equal to 0.

[0176] The $\text{nnpfc_pic_height_num_minus1}$ plus 1 and $\text{nnpfc_pic_height_denom_minus1}$ plus 1 specify the numerator and denominator, respectively, for the resampling ratio of the NNPF output picture height relative to CroppedHeight . The value of $(\text{nnpfc_pic_height_num_minus1} + 1) \div (\text{nnpfc_pic_height_denom_minus1} + 1)$ shall be in the range of $1 \div 16$ to 16, inclusive. When $\text{nnpfc_pic_height_num_minus1}$ and $\text{nnpfc_pic_height_denom_minus1}$ are not present, the values of $\text{nnpfc_pic_height_num_minus1}$ and $\text{nnpfc_pic_height_denom_minus1}$ are both inferred to be equal to 0.

[0177] The variable $\text{nnpfcOutputPicHeight}$, representing the height of the luma sample arrays of the picture(s) resulting from applying the NNPF identified by nnpfc_id to the input picture(s), is derived as follows:

[00003]

$\text{nnpfcOutputPicHeight} = \text{Ceil}(\text{CroppedHeight} * (\text{nnpfc_pic_height_num_minus1} + 1) \div (\text{nnpfc_pic_height_denom_minus1} + 1))$ [Equation3]

[0178] It is a requirement of bitstream conformance that the value of $\text{nnpfcOutputPicHeight} \% \text{outSubHeightC}$ shall be equal to 0.

[0179] When $\text{nnpfc_pic_width_num_minus1}$, $\text{nnpfc_pic_width_denom_minus1}$, $\text{nnpfc_pic_height_num_minus1}$, and $\text{nnpfc_pic_height_denom_minus1}$ are present, at least one the following shall be true: [0180] The value of $\text{nnpfcOutputPicWidth}$ is not equal to CroppedWidth . [0181] The value of $\text{nnpfcOutputPicHeight}$ is not equal to CroppedHeight .

[0182] The $\text{nnpfc_interpolated_pics}[i]$ specifies the number of interpolated pictures generated by the NNPF between the i -th and the $(i+1)$ -th picture used as input for the NNPF. The value of $\text{nnpfc_interpolated_pics}[i]$ shall be in the range of 0 to 63, inclusive.

[0183] The value of $\text{nnpfc_interpolated_pics}[i]$ shall be greater than 0 for at least one value of i in the range of 0 to $\text{nnpfc_num_input_pics_minus1} - 1$, inclusive.

[0184] The variables $\text{NumInpPicsInOutputTensor}$, specifying the number of pictures that have a corresponding input picture and are present in the output tensor of the NNPF, $\text{InpIdx}[\text{idx}]$ specifying the input picture index of the idx -th picture that is present in the output tensor of the NNPF and has a corresponding input picture, and numOutputPics , specifying the total number of pictures present in the output tensor of the NNPF, are derived as follows:

TABLE-US-00006 TABLE 6 for($i = 0$, $\text{numOutputPics} = 0$; $i < \text{numInputPics}$; $i++$) if($\text{nnpfc_input_pic_output_flag}[i]$) {
 $\text{InpIdx}[\text{numOutputPics}] = i$ $\text{numOutputPics}++$ } $\text{NumInpPicsInOutputTensor} = \text{numOutputPics}$ if(
 $\text{pictureRateUpsamplingFlag}$) for($i = 0$; $i \leq \text{numInputPics} - 2$; $i++$) $\text{numOutputPics} += \text{nnpfc_interpolated_pics}[i]$

[0185] The $\text{nnpfc_component_last_flag}$ equal to 1 indicates that the last dimension in the input tensor inputTensor to the NNPF and the output tensor outputTensor resulting from the NNPF is used for a current channel. $\text{nnpfc_component_last_flag}$ equal to 0 indicates that the third dimension in the input tensor inputTensor to the NNPF and the output tensor outputTensor resulting from the NNPF is used for a current channel.

[0186] The first dimension in the input tensor and in the output tensor is used for the batch index, which is a practice in some neural

network framework. While formulae of this SEI message use the batch size corresponding to the batch index equal to 0, it is up to the post-processing implementation to determine the batch size used as input to the neural network inference.

[0187] For example, when `nnpfc_inp_order_idc` is equal to 3 and `nnpfc_auxiliary_inp_idc` is equal to 1, there are 7 channels in the input tensor, including four luma matrices, two chroma matrices, and one auxiliary input matrix. In this case, the process `DeriveInputTensors()` would derive each of these 7 channels of the input tensor one by one, and when a particular channel of these channels is processed, that channel is referred to as the current channel during the process.

[0188] The `nnpfc_inp_format_idc` indicates the method of converting a sample value of the input picture to an input value to the NNPF. When `nnpfc_inp_format_idc` is equal to 0, the input values to the NNPF are real numbers and the functions `InpY()` and `InpC()` are specified as follows:

$$\begin{aligned} \text{InpY}(x) &= x \div ((1 \ll \text{BitDepth}_Y) - 1) \\ \text{InpC}(x) &= x \div ((1 \ll \text{BitDepth}_C) - 1) \end{aligned} \quad [\text{Equation4}]$$

[0189] When `nnpfc_inp_format_idc` is equal to 1, the input values to the NNPF are unsigned integer numbers and the functions `InpY()` and `InpC()` are specified as follows:

TABLE-US-00007 TABLE 7

$\text{shiftY} = \text{BitDepth.sub.Y} - \text{inpTensorBitDepth.sub.Y}$ if ($\text{inpTensorBitDepth.sub.Y} > \text{BitDepth.sub.Y}$)	$\text{InpY}(x) = x \ll (\text{inpTensorBitDepth.sub.Y} - \text{BitDepth.sub.Y})$ else	$\text{InpY}(x) = \text{Clip3}(0, (1 \ll \text{inpTensorBitDepth.sub.Y}) - 1, (x + (1 \ll (\text{shiftY} - 1))) \gg \text{shiftY})$
$\text{shiftC} = \text{BitDepth.sub.C} - \text{inpTensorBitDepth.sub.C}$ if ($\text{inpTensorBitDepth.sub.C} \geq \text{BitDepth.sub.C}$)	$\text{InpC}(x) = x \ll (\text{inpTensorBitDepth.sub.C} - \text{BitDepth.sub.C})$ else	$\text{InpC}(x) = \text{Clip3}(0, (1 \ll \text{inpTensorBitDepth.sub.C}) - 1, (x + (1 \ll (\text{shiftC} - 1))) \gg \text{shiftC})$

[0190] The variable `inpTensorBitDepthY` is derived from the syntax element `nnpfc_inp_tensor_luma_bitdepth_minus8` as specified below. The variable `inpTensorBitDepthC` is derived from the syntax element `nnpfc_inp_tensor_chroma_bitdepth_minus8` as specified below.

[0191] Values of `nnpfc_inp_format_idc` greater than 1 are reserved for future specification by ITU-T|ISO/IEC and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPF SEI messages that contain reserved values of `nnpfc_inp_format_idc`.

[0192] The `nnpfc_auxiliary_inp_idc` greater than 0 indicates that auxiliary input data is present in the input tensor of the NNPF. `nnpfc_auxiliary_inp_idc` equal to 0 indicates that auxiliary input data is not present in the input tensor. `nnpfc_auxiliary_inp_idc` equal to 1 specifies that auxiliary input data is derived as specified in Formula 85.

[0193] The value of `nnpfc_auxiliary_inp_idc` shall be in the range of 0 to 1, inclusive, in bitstreams conforming to this edition of this document. Values of 2 to 255, inclusive, for `nnpfc_auxiliary_inp_idc` are reserved for future use and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPF SEI messages with `nnpfc_auxiliary_inp_idc` in the range of 2 to 255, inclusive. Values of `nnpfc_auxiliary_inp_idc` greater than 255 shall not be present in bitstreams conforming to this edition of this document and are not reserved for future use.

[0194] The `nnpfc_inp_order_idc` indicates the method of ordering the sample arrays of an input picture to form an input tensor to the NNPF.

[0195] The value of `nnpfc_inp_order_idc` shall be in the range of 0 to 3, inclusive, in bitstreams conforming to this edition of this document. Values of 4 to 255, inclusive, for `nnpfc_inp_order_idc` are reserved for future use by ITU-T|ISO/IEC and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPF SEI messages with `nnpfc_inp_order_idc` in the range of 4 to 255, inclusive. Values of `nnpfc_inp_order_idc` greater than 255 shall not be present in bitstreams conforming to this edition of this document and are not reserved for future use.

[0196] When `ChromaFormatIdc` is not equal to 1, `nnpfc_inp_order_idc` shall not be equal to 3.

[0197] When `ChromaFormatIdc` is equal to 0, `nnpfc_inp_order_idc` shall be equal to 0.

[0198] When `chromaUpsamplingFlag` is equal to 1, `nnpfc_inp_order_idc` shall not be equal to 0.

[0199] Table 8 contains an informative description of `nnpfc_inp_order_idc` values.

TABLE-US-00008 TABLE 8 `nnpfc_inp_order_idc` Description

0	If <code>nnpfc_auxiliary_inp_idc</code> is equal to 0, one luma matrix is present in the input tensor for each input picture, and the number of channels is 1. Otherwise, when <code>nnpfc_auxiliary_inp_idc</code> is equal to 1, one luma matrix and one auxiliary input matrix are present, and the number of channels is 2.
1	If <code>nnpfc_auxiliary_inp_idc</code> is equal to 0, two chroma matrices are present in the input tensor, and the number of channels is 2. Otherwise, when <code>nnpfc_auxiliary_inp_idc</code> is equal to 1, two chroma matrices and one auxiliary input matrix are present, and the number of channels is 3.
2	If <code>nnpfc_auxiliary_inp_idc</code> is equal to 0, one luma and two chroma matrices are present in the input tensor, and the number of channels is 3. Otherwise, when <code>nnpfc_auxiliary_inp_idc</code> is equal to 1, one luma matrix, two chroma matrices and one auxiliary input matrix are present, and the number of channels is 4.
3	If <code>nnpfc_auxiliary_inp_idc</code> is equal to 0, four luma matrices and two chroma matrices are present in the input tensor, and the number of channels is 6. Otherwise, when <code>nnpfc_auxiliary_inp_idc</code> is equal to 1, four luma matrices, two chroma matrices, and one auxiliary input matrix are present in the input tensor, and the number of channels is 7. The luma channels are derived in an interleaved manner as illustrated in FIG. 12. This <code>nnpfc_inp_order_idc</code> can only be used when the input chroma format is 4:2:0.
4 . . . 255	Reserved

[0200] The `nnpfc_inp_tensor_luma_bitdepth_minus8` plus 8 specifies the bit depth of luma sample values in the input integer tensor. The value of `inpTensorBitDepthY` is derived as follows:

$$\text{inpTensorBitDepth}_Y = \text{nnpfc_inp_tensor_luma_bitdepth_minus8} + 8 \quad [\text{Equation5}]$$

[0201] It is a requirement of bitstream conformance that the value of `nnpfc_inp_tensor_luma_bitdepth_minus8` shall be in the range of 0 to 24, inclusive.

[0202] `nnpfc_inp_tensor_chroma_bitdepth_minus8` plus 8 specifies the bit depth of chroma sample values in the input integer tensor. The value of `inpTensorBitDepthC` is derived as follows:

$$\text{inpTensorBitDepth}_C = \text{nnpfc_inp_tensor_chroma_bitdepth_minus8} + 8 \quad [\text{Equation6}]$$

[0203] It is a requirement of bitstream conformance that the value of `nnpfc_inp_tensor_chroma_bitdepth_minus8` shall be in the range of 0 to 24, inclusive.

[0204] When nnpfc_auxiliary_inpn_idc is equal to 1, the variable strengthControlScaledVal is derived as follows:

```
TABLE-US-00009 TABLE 9    for( i = 0; i < numInputPics; i++ )    if( nnpfc_inpn_format_idc == 1 )    if(
nnpfc_inpn_order_idc == 0 || nnpfc_inpn_order_idc == 2 ||                nnpfc_inpn_order_idc == 3 )
strengthControlScaledVal[ i ] =                Floor ( StrengthControlVal[ i ] * ( ( 1 << inpnTensorBitDepthY ) - 1 ) )    else
if( nnpfc_inpn_order_idc == 1 )                strengthControlScaledVal[ i ] =                Floor ( StrengthControlVal[ i ] * ( ( 1
<< inpnTensorBitDepthC ) - 1 ) )    else                strengthControlScaledVal[ i ] = StrengthControlVal[ i ]
```

[0205] A patch is a rectangular array of samples from a component (e.g., a luma or chroma component) of a picture.

[0206] The process DeriveInputTensors() for deriving the input tensor inputTensor for a given vertical sample coordinate cTop and a horizontal sample coordinate cLeft specifying the top-left sample location for the patch of samples included in the input tensor, is specified as follows:

```
TABLE-US-00010 TABLE 10    for( i = 0; i < numInputPics; i++ ) {    if( nnpfc_inpn_order_idc == 0 )        for( yP =
-nnpfc_overlap; yP < inpnPatchHeight + nnpfc_overlap; yP++)        for( xP = -nnpfc_overlap; xP < inpnPatchWidth +
nnpfc_overlap; xP++ ) {            inpnVal = InpnY( InpnSampleVal( cTop + yP, cLeft + xP, CroppedHeight,
CroppedWidth, CroppedYPic[ i ], 0 ) )            yPovlp = yP + nnpfc_overlap                xPovlp = xP + nnpfc_overlap
            if( !nnpfc_component_last_flag )                inputTensor[ 0 ][ i ][ 0 ][ yPovlp ][ xPovlp ] = inpnVal
            else                inputTensor[ 0 ][ i ][ yPovlp ][ xPovlp ][ 0 ] = inpnVal                if( nnpfc_auxiliary_inpn_idc
== 1 )                if( !nnpfc_component_last_flag )                inputTensor[ 0 ][ i ][ 1 ][ yPovlp ][ xPovlp ] =
strengthControlScaledVal[ i ]                else                inputTensor[ 0 ][ i ][ yPovlp ][ xPovlp ][ 1 ] =
strengthControlScaledVal[ i ]        }    else if( nnpfc_inpn_order_idc == 1 )        for( yP = -nnpfc_overlap; yP <
inpnPatchHeight + nnpfc_overlap; yP++)        for( xP = -nnpfc_overlap; xP < inpnPatchWidth + nnpfc_overlap; xP++ ) {

[0207] The nnpfc_out_format_idc equal to 0 indicates that the sample values output by the NNPF are real numbers where the value range of 0 to 1, inclusive, maps linearly to the unsigned integer value range of 0 to (1<<bitDepth)-1, inclusive, for any desired bit depth bitDepth for subsequent post-processing or displaying.

[0208] The `nnpfc_out_format_idc` output by the NNPF are unsigned integer numbers in the range of 0 to $(1 \ll \text{outTensorBitDepthY}) - 1$, inclusive, and the chroma sample values output by the NNPF are unsigned integer numbers in the range of 0 to $(1 \ll \text{outTensorBitDepthC}) - 1$, inclusive.

[0209] Values of `nnpfc_out_format_idc` greater than 1 are reserved for future specification by ITU-T|ISO/IEC and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPF SEI messages that contain reserved values of `nnpfc_out_format_idc`.

[0210] The `nnpfc_out_order_idc` indicates the output order of samples resulting from the NNPF.

[0211] The value of `nnpfc_out_order_idc` shall be in the range of 0 to 3, inclusive, in bitstreams conforming to this edition of this document. Values of 4 to 255, inclusive, for `nnpfc_out_order_idc` are reserved for future use by ITU-T|ISO/IEC and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPF SEI messages with `nnpfc_out_order_idc` in the range of 4 to 255, inclusive. Values of `nnpfc_out_order_idc` greater than 255 shall not be present in bitstreams conforming to this edition of this document and are not reserved for future use.

[0212] When `chromaUpsamplingFlag` is equal to 1, `nnpfc_out_order_idc` shall not be equal to 0 or 3.

[0213] When `colourizationFlag` is equal to 1, `nnpfc_out_order_idc` shall not be equal to 0.

[0214] Table 13 contains an informative description of `nnpfc_out_order_idc` values.

TABLE-US-00013 TABLE 13 `nnpfc_out_order_idc` Description

0	Only the luma matrix is present in the output tensor, thus the number of channels is 1.
1	Only the chroma matrices are present in the output tensor, thus the number of channels is 2.
2	The luma and chroma matrices are present in the output tensor, thus the number of channels is 3.
3	Four luma matrices and two chroma matrices are present in the output tensor, thus the number of channels is 6.
This <code>nnpfc_out_order_idc</code> can only be used when the output chroma format is 4:2:0.	
4 . . . 255	Reserved

[0215] The `nnpfc_out_tensor_luma_bitdepth_minus8` plus 8 specifies the bit depth of luma sample values in the output integer tensor. The value of `nnpfc_out_tensor_luma_bitdepth_minus8` shall be in the range of 0 to 24, inclusive. The value of `outTensorBitDepthY` is derived as follows:

[00007] $\text{outTensorBitDepth}_Y = \text{nnpfc_out_tensor_luma_bitdepth_minus8} + 8$ [Equation7]

[0216] The `nnpfc_out_tensor_chroma_bitdepth_minus8` plus 8 specifies the bit depth of chroma sample values in the output integer tensor. The value of `nnpfc_out_tensor_chroma_bitdepth_minus8` shall be in the range of 0 to 24, inclusive. The value of `outTensorBitDepthC` is derived as follows:

[00008] $\text{outTensorBitDepth}_Y = \text{nnpfc_out_tensor_luma_bitdepth_minus8} + 8$ [Equation8]

[0217] When `bitDepthUpsamplingFlag` is equal to 1, the value of `nnpfc_out_format_idc` shall be equal to 1 and at least one of the following conditions shall be true:

[0218] The `nnpfc_out_tensor_luma_bitdepth_minus8` is present and `outTensorBitDepthY` is greater than `BitDepthY`. [0219] The `nnpfc_out_tensor_chroma_bitdepth_minus8` is present and `outTensorBitDepthC` is greater than `BitDepthC`.

[0220] When `nnpfc_inp_tensor_luma_bitdepth_minus8`, `nnpfc_inp_tensor_chroma_bitdepth_minus8`, `nnpfc_out_tensor_luma_bitdepth_minus8`, and `nnpfc_out_tensor_chroma_bitdepth_minus8` are present and `outTensorBitDepthY` is greater than `inpTensorBitDepthY`, `outTensorBitDepthC` shall not be less than `inpTensorBitDepthC`.

[0221] When `nnpfc_inp_tensor_luma_bitdepth_minus8`, `nnpfc_inp_tensor_chroma_bitdepth_minus8`, `nnpfc_out_tensor_luma_bitdepth_minus8`, and `nnpfc_out_tensor_chroma_bitdepth_minus8` are present and `outTensorBitDepthC` is greater than `inpTensorBitDepthC`, `outTensorBitDepthY` shall not be less than `inpTensorBitDepthY`.

[0222] The process `StoreOutputTensors()` for deriving sample values in the filtered output sample arrays `FilteredYPic`, `FilteredCbPic`, and `FilteredCrPic` from the output tensor `outputTensor` for a given vertical sample coordinate `cTop` and a horizontal sample coordinate `cLeft` specifying the top-left sample location for the patch of samples included in the input tensor, is specified as follows:

TABLE-US-00014 TABLE 14

```
for( i = 0; i < numOutputPics; i++ ) { if( nnpfc_out_order_idc == 0 ) for( yP = 0; yP < outPatchHeight; yP++ ) for( xP = 0; xP < outPatchWidth; xP++ ) { yY = cTop * outPatchHeight / inpPatchHeight + yP xY = cLeft * outPatchWidth / inpPatchWidth + xP if( yY < nnpfcOutputPicHeight && xY < nnpfcOutputPicWidth ) if( !nnpfc_component_last_flag ) FilteredYPic[ i ][ xY ][ yY ] = outputTensor[ 0 ][ i ][ 0 ][ yP ][ xP ] } else if( nnpfc_out_order_idc == 1 ) for( yP = 0; yP < outPatchHeight; yP++ ) for( xP = 0; xP < outPatchWidth; xP++ ) { xSrc = cLeft * horCScaling + xP ySrc = cTop * verCScaling + yP if( ySrc < nnpfcOutputPicHeight / outSubHeightC && outSubWidthC ) if( !nnpfc_component_last_flag ) { FilteredCbPic[ i ][ xSrc ][ ySrc ] = outputTensor[ 0 ][ i ][ 0 ][ yP ][ xP ] } else { FilteredCrPic[ i ][ xSrc ][ ySrc ] = outputTensor[ 0 ][ i ][ 1 ][ yP ][ xP ] } } else if( nnpfc_out_order_idc == 2 ) for( yP = 0; yP < outPatchHeight; yP++ ) for( xP = 0; xP < outPatchWidth; xP++ ) { yY = cTop * outPatchHeight / inpPatchHeight + yP xY = cLeft * outPatchWidth / inpPatchWidth + xP yC = yY / outSubHeightC xC = xY / outSubWidthC yPc = ( yP / outSubHeightC ) * outSubHeightC xPc = ( xP / outSubWidthC ) * outSubWidthC if( yY < nnpfcOutputPicHeight && xY < nnpfcOutputPicWidth ) if( !nnpfc_component_last_flag ) { FilteredYPic[ i ][ xY ][ yY ] = outputTensor[ 0 ][ i ][ 0 ][ yP ][ xP ] FilteredCbPic[ i ][ xC ][ yC ] = outputTensor[ 0 ][ i ][ 1 ][ yPc ][ xPc ] FilteredCrPic[ i ][ xC ][ yC ] = outputTensor[ 0 ][ i ][ 2 ][ yPc ][ xPc ] } else { FilteredYPic[ i ][ xY ][ yY ] = outputTensor[ 0 ][ i ][ 0 ][ yP ][ xP ] FilteredCbPic[ i ][ xC ][ yC ] = outputTensor[ 0 ][ i ][ 1 ][ yPc ][ xPc ] FilteredCrPic[ i ][ xC ][ yC ] = outputTensor[ 0 ][ i ][ 2 ][ yPc ][ xPc ] } } else if( nnpfc_out_order_idc == 3 ) for( yP = 0; yP < outPatchHeight; yP++ ) for( xP = 0; xP < outPatchWidth; xP++ ) { ySrc = cTop / 2 * outPatchHeight / inpPatchHeight + yP xSrc = cLeft / 2 * outPatchWidth / inpPatchWidth + xP if( ySrc < nnpfcOutputPicHeight / 2 && xSrc < nnpfcOutputPicWidth / 2 ) if( !nnpfc_component_last_flag ) { FilteredYPic[ i ][

FilteredCrPic[ i ][ xSrc ][ ySrc ] = outputTensor[ 0 ][ i ][ yP ][ xP ][ 5 ]
} } }

```

[0223] The `nnpfc_separate_colour_description_present_flag` equal to 1 indicates that a distinct combination of colour primaries, transfer characteristics, matrix coefficients, and scaling and offset values applied in association with the matrix coefficients for the picture resulting from the NNPF is specified in the SEI message syntax structure. `nnpfc_separate_colour_description_present_flag` equal to 0 indicates that the combination of colour primaries, transfer characteristics, matrix coefficients, and scaling and offset values applied in association with the matrix coefficients for the picture resulting from the NNPF is the same as indicated in VUI parameters for the CLVS.

[0224] The `nnpfc_colour_primaries` has the same semantics as specified in subclause 7.3 for the `vui_colour_primaries` syntax element, except as follows:

[0225] `nnpfc_colour_primaries` specifies the colour primaries of the picture resulting from applying the NNPF specified in the SEI message, rather than the colour primaries used for the CLVS. [0226] When `nnpfc_colour_primaries` is not present in the NNPF SEI message, the value of `nnpfc_colour_primaries` is inferred to be equal to `vui_colour_primaries`.

[0227] The `nnpfc_transfer_characteristics` has the same semantics as specified in subclause 7.3 for the `vui_transfer_characteristics` syntax element, except as follows: [0228] `nnpfc_transfer_characteristics` specifies the transfer characteristics of the picture resulting from applying the NNPF specified in the SEI message, rather than the transfer characteristics used for the CLVS. [0229] When `nnpfc_transfer_characteristics` is not present in the NNPF SEI message, the value of `nnpfc_transfer_characteristics` is inferred to be equal to `vui_transfer_characteristics`.

[0230] The `nnpfc_matrix_coeffs` describes the equations used in deriving luma and chroma signals from the green, blue, and red, or Y, Z, and X primaries. Its semantics apply to the pictures resulting from applying the NNPF specified in this SEI message and are as specified for `MatrixCoefficients` in Rec. ITU-T H.273|ISO/IEC 23091-2 with `BitDepthY` and `BitDepthC` being equal to `outTensorBitDepthY` and `outTensorBitDepthC`, respectively.

[0231] When `nnpfc_matrix_coeffs` is not present in the NNPF SEI message, the value of `nnpfc_matrix_coeffs` is inferred to be equal to `vui_matrix_coeffs`.

[0232] The `nnpfc_matrix_coeffs` shall not be equal to 0 unless both of the following conditions are true: [0233] `nnpfc_out_tensor_chroma_bitdepth_minus8` is equal to `nnpfc_out_tensor_luma_bitdepth_minus8`. [0234] `nnpfc_out_order_idc` is equal to 2, `outSubHeightC` is equal to 1, and `outSubWidthC` is equal to 1.

[0235] The `nnpfc_matrix_coeffs` shall not be equal to 8 unless one of the following conditions is true: [0236] `nnpfc_out_tensor_chroma_bitdepth_minus8` is equal to `nnpfc_out_tensor_luma_bitdepth_minus8`. [0237] `nnpfc_out_tensor_chroma_bitdepth_minus8` is equal to `nnpfc_out_tensor_luma_bitdepth_minus8`+1, `nnpfc_out_order_idc` is equal to 2, `outSubHeightC` is equal to 1, and `outSubWidthC` is equal to 1.

[0238] The `nnpfc_full_range_flag` indicates the scaling and offset values applied in association with the matrix coefficients as specified by `nnpfc_matrix_coeffs`. Its semantics are as specified for the `VideoFullRangeFlag` parameter in Rec. ITU-T H.273|ISO/IEC 23091-2. When not present, the value of `nnpfc_full_range_flag` is inferred to be equal to 0.

[0239] The `nnpfc_chroma_loc_info_present_flag` equal to 1 indicates the presence of the `nnpfc_chroma_sample_loc_type_frame` syntax element in the NNPF SEI message. `nnpfc_chroma_loc_info_present_flag` equal to 0 indicates the absence of the `nnpfc_chroma_sample_loc_type_frame` syntax element in the NNPF SEI message. When `colourizationFlag` is equal to 0 or `nnpfc_out_colour_format_idc` is not equal to 1, the value of `nnpfc_chroma_loc_info_present_flag` shall be equal to 0.

[0240] The `nnpfc_chroma_sample_loc_type_frame`, when not equal to 6 and `nnpfc_out_colour_format_idc` is equal to 1, specifies the location of chroma samples of the output pictures, as shown in FIG. 1. `nnpfc_chroma_sample_loc_type_frame` equal to 6 and `nnpfc_out_colour_format_idc` equal to 1 indicates that the location of the chroma samples is unknown or unspecified or specified by other means not specified in this document. The value of `nnpfc_chroma_sample_loc_type_frame` shall be in the range of 0 to 6, inclusive.

[0241] The `nnpfc_overlap` indicates the overlapping horizontal and vertical sample counts of adjacent input tensors of the NNPF. The value of `nnpfc_overlap` shall be in the range of 0 to 16383, inclusive. `nnpfc_constant_patch_size_flag` equal to 1 indicates that the NNPF accepts exactly the patch indicated size by `nnpfc_patch_width_minus1` and `nnpfc_patch_height_minus1` as input. `nnpfc_constant_patch_size_flag` equal to 0 indicates that the NNPF accepts as input any patch size with width `inpPatchWidth` and height `inpPatchHeight` such that the width of an extended patch (i.e., a patch plus the overlapping area), which is equal to `inpPatchWidth+2*nnpfc_overlap`, is a positive integer multiple of `nnpfc_extended_patch_width_cd_delta_minus1+1+2*nnpfc_overlap`, and the height of the extended patch, which is equal to `inpPatchHeight+2*nnpfc_overlap`, is a positive integer multiple of `nnpfc_extended_patch_height_cd_delta_minus1+1+2*nnpfc_overlap`.

[0242] The `nnpfc_patch_width_minus1` plus 1, when `nnpfc_constant_patch_size_flag` equal to 1, indicates the horizontal sample counts of the patch size required for the input to the NNPF. The value of `nnpfc_patch_width_minus1` shall be in the range of 0 to `Min(32766, CroppedWidth-1)`, inclusive.

[0243] The `nnpfc_patch_height_minus1` plus 1, when `nnpfc_constant_patch_size_flag` equal to 1, indicates the vertical sample counts of the patch size required for the input to the NNPF. The value of `nnpfc_patch_height_minus1` shall be in the range of 0 to `Min(32766, CroppedHeight-1)`, inclusive.

[0244] The `nnpfc_extended_patch_width_cd_delta_minus1` plus 1 plus `2*nnpfc_overlap`, when `nnpfc_constant_patch_size_flag` equal to 0, indicates a common divisor of all allowed values of the width of an extended patch required for the input to the NNPF. The value

of nnpfc_extended_patch_width_minus1 shall be in the range of 0 to Min(32766, CroppedWidth-1), inclusive. [0245] The nnpfc_extended_patch_height_cd_delta_minus1 plus 1 plus 2*nnpfc_overlap, when nnpfc_constant_patch_size_flag equal to 0, indicates a common divisor of all allowed values of the height of an extended patch required for the input to the NNPF. The value of nnpfc_extended_patch_height_cd_delta_minus1 shall be in the range of 0 to Min(32766, CroppedHeight-1), inclusive. [0246] Let the variables inpPatchWidth and inpPatchHeight be the patch size width and the patch size height, respectively. [0247] If nnpfc_constant_patch_size_flag is equal to 0, the following applies: [0248] The values of inpPatchWidth and inpPatchHeight are either provided by external means not specified in this document or set by the post-processor itself. [0249] The value of inpPatchWidth+2*nnpfc_overlap shall be a positive integer multiple of nnpfc_extended_patch_width_cd_delta_minus1+1+2*nnpfc_overlap and inpPatchWidth shall be less than or equal to CroppedWidth. The value of inpPatchHeight+2*nnpfc_overlap shall be a positive integer multiple of nnpfc_extended_patch_height_cd_delta_minus1+1+2*nnpfc_overlap and inpPatchHeight shall be less than or equal to CroppedHeight.

[0250] Otherwise (nnpfc_constant_patch_size_flag is equal to 1), the value of inpPatchWidth is set equal to nnpfc_patch_width_minus1+1 and the value of inpPatchHeight is set equal to nnpfc_patch_height_minus1+1.

[0251] The variables outPatchWidth, outPatchHeight, horCScaling, verCScaling, outPatchCWidth, and outPatchCHeight are derived as follows:

TABLE-US-00016 TABLE 16
$$\text{outPatchWidth} = (\text{nnpfcOutputPicWidth} * \text{inpPatchWidth}) / \text{CroppedWidth}$$

$$\text{outPatchHeight} = (\text{nnpfcOutputPicHeight} * \text{inpPatchHeight}) / \text{CroppedHeight}$$

$$\text{horCScaling} = \text{SubWidthC} / \text{outSubWidthC}$$

$$\text{verCScaling} = \text{SubHeightC} / \text{outSubHeightC}$$

$$\text{outPatchCWidth} = \text{outPatchWidth} * \text{horCScaling}$$

$$\text{outPatchCHeight} = \text{outPatchHeight} * \text{verCScaling}$$

[0252] It is a requirement of bitstream conformance that outPatchWidth*CroppedWidth shall be equal to nnpfcOutputPicWidth*inpPatchWidth and outPatchHeight*CroppedHeight shall be equal to nnpfcOutputPicHeight*inpPatchHeight.

[0253] The nnpfc_padding_type indicates the process of padding when referencing sample locations outside the boundaries of the input picture as described in Table 17. The value of nnpfc_padding_type shall be in the range of 0 to 4, inclusive, in bitstreams conforming to this edition of this document. Values of 5 to 15, inclusive, for nnpfc_padding_type are reserved for future use and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPF SEI messages with nnpfc_padding_type in the range of 5 to 15, inclusive. Values of nnpfc_padding_type greater than 15 shall not be present in bitstreams conforming to this edition of this document and are not reserved for future use.

TABLE-US-00017 TABLE 17 nnpfc_padding_type Description 0 Zero padding 1 Replication padding 2 Reflection padding 3 Wrap-around padding 4 Fixed padding 5 . . . 15 reserved

[0254] The nnpfc_luma_padding_val indicates the luma value to be used for padding when nnpfc_padding_type is equal to 4. The value of nnpfc_luma_padding_val shall be in the range of 0 to (1<<BitDepthY)-1, inclusive.

[0255] The nnpfc_cb_padding_val indicates the Cb value to be used for padding when nnpfc_padding_type is equal to 4. The value of nnpfc_cb_padding_val shall be in the range of 0 to (1<<BitDepthC)-1, inclusive.

[0256] The nnpfc_cr_padding_val indicates the Cr value to be used for padding when nnpfc_padding_type is equal to 4. The value of nnpfc_cr_padding_val shall be in the range of 0 to (1<<BitDepthC)-1, inclusive.

[0257] The function InpSampleVal(y, x, picHeight, picWidth, croppedPic, cIdx) with inputs being a vertical sample location y, a horizontal sample location x, a picture height picHeight, a picture width picWidth, sample array croppedPic, and component index cIdx (equal to 0 for luma, 1 for Cb, and 2 for Cr) returns the value of sample Val derived as follows:

[0258] For the inputs to the function InpSampleVal() the vertical location is listed before the horizontal location for compatibility with input tensor conventions of some inference engines.

TABLE-US-00018 TABLE 18
$$\text{sampleVal} = 0 \quad \text{if}(\text{nnpfc_padding_type} = 0) \quad \text{if}(y < 0 \parallel x < 0 \parallel y \geq \text{picHeight} \parallel x \geq \text{picWidth})$$

$$\text{sampleVal} = \text{croppedPic}[x][y] \quad \text{else if}(\text{nnpfc_padding_type} = 1) \quad \text{sampleVal} = \text{croppedPic}[\text{Clip3}(0, \text{picWidth} - 1, x)][\text{Clip3}(0, \text{picHeight} - 1, y)]$$

$$\text{sampleVal} = \text{croppedPic}[\text{Reflect}(\text{picWidth} - 1, x)][\text{Reflect}(\text{picHeight} - 1, y)] \quad \text{else if}(\text{nnpfc_padding_type} = 2) \quad \text{sampleVal} = \text{croppedPic}[\text{Reflect}(\text{picWidth} - 1, x)][\text{Reflect}(\text{picHeight} - 1, y)]$$

$$\text{sampleVal} = \text{croppedPic}[\text{Wrap}(\text{picWidth} - 1, x)][y] \quad \text{else if}(\text{nnpfc_padding_type} = 3) \quad \text{if}(y \geq 0 \&\& y < \text{picHeight})$$

$$\text{sampleVal} = \text{croppedPic}[y][x] \quad \text{else if}(\text{nnpfc_padding_type} = 4) \quad \text{if}(y < 0 \parallel x < 0 \parallel y \geq \text{picHeight} \parallel x \geq \text{picWidth})$$

$$\text{sampleVal} = (\text{cIdx} == 0 ? \text{nnpfc_luma_padding_val} : (\text{cIdx} == 1 ? \text{nnpfc_cb_padding_val} : \text{nnpfc_cr_padding_val})) \quad \text{else} \quad \text{sampleVal} = \text{croppedPic}[x][y]$$

[0259] An NNPF PostProcessingFilter() is the target NNPF as derived in the semantics of the NNPF SEI message. The following example process may be used, with the NNPF PostProcessingFilter() to generate, in a patch-wise manner, the filtered and/or interpolated picture(s), which contain Y, Cb, and Cr sample arrays FilteredYPic, FilteredCbPic, and FilteredCrPic, respectively, as indicated by nnpfc_out_order_idc:

TABLE-US-00019 TABLE 19
$$\text{if}(\text{nnpfc_inp_order_idc} = 0 \parallel \text{nnpfc_inp_order_idc} = 2) \quad \text{for}(\text{cTop} = 0; \text{cTop} < \text{CroppedHeight}; \text{cTop} += \text{inpPatchHeight}) \quad \text{for}(\text{cLeft} = 0; \text{cLeft} < \text{CroppedWidth}; \text{cLeft} += \text{inpPatchWidth}) \{$$

$$\text{DeriveInputTensors()} \quad \text{outputTensor} = \text{PostProcessingFilter}(\text{inputTensor}) \quad \text{StoreOutputTensors}() \quad \}$$

$$\text{else if}(\text{nnpfc_inp_order_idc} = 1) \quad \text{for}(\text{cTop} = 0; \text{cTop} < \text{CroppedHeight} / \text{SubHeightC}; \text{cTop} += \text{inpPatchHeight}) \quad \text{for}(\text{cLeft} = 0; \text{cLeft} < \text{CroppedWidth} / \text{SubWidthC}; \text{cLeft} += \text{inpPatchWidth}) \{$$

$$\text{DeriveInputTensors()} \quad \text{outputTensor} = \text{PostProcessingFilter}(\text{inputTensor}) \quad \text{StoreOutputTensors}() \quad \}$$

$$\text{else if}(\text{nnpfc_inp_order_idc} = 3) \quad \text{for}(\text{cTop} = 0; \text{cTop} < \text{CroppedHeight}; \text{cTop} += \text{inpPatchHeight} * 2) \quad \text{for}(\text{cLeft} = 0; \text{cLeft} < \text{CroppedWidth}; \text{cLeft} += \text{inpPatchWidth} * 2) \{$$

$$\text{DeriveInputTensors()} \quad \text{outputTensor} = \text{PostProcessingFilter}(\text{inputTensor}) \quad \text{StoreOutputTensors}() \quad \}$$

[0260] An NNPF-generated picture with index i contains sample arrays FilteredYPic[i], FilteredCbPic[i], and FilteredCrPic[i], when present, that are derived by Formula 99. An NNPF-generated picture does not include the overlap regions.

[0261] The NNPF process consists of the process defined by Formula 99 followed by outputting NNPF-generated pictures in their increasing index order, where all NNPF-generated pictures that were interpolated by the NNPF are output and those NNPF-generated pictures that correspond to any input pictures to the NNPF are output as specified in the semantics of the NNPF SEI message.

[0262] The nnpfc_complexity_info_present_flag equal to 1 specifies that one or more syntax elements that indicate the complexity of the NNPF associated with the nnpfc_id are present. nnpfc_complexity_info_present_flag equal to 0 specifies that no syntax elements that indicate the complexity of the NNPF associated with the nnpfc_id are present.

[0263] The `nnpfc_parameter_type_idc` equal to 0 indicates that the neural network uses only integer parameters. `nnpfc_parameter_type_flag` equal to 1 indicates that the neural network may use floating point or integer parameters. `nnpfc_parameter_type_idc` equal to 2 indicates that the neural network uses only binary parameters. `nnpfc_parameter_type_idc` equal to 3 is reserved for future use by ITU-T|ISO/IEC and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPFC SEI messages with `nnpfc_parameter_type_idc` equal to 3.

[0264] The `nnpfc_log2_parameter_bit_length_minus3` equal to 0, 1, 2, and 3 indicates that the neural network does not use parameters of bit length greater than 8, 16, 32, and 64, respectively. When `nnpfc_parameter_type_idc` is present and `nnpfc_log2_parameter_bit_length_minus3` is not present, the neural network does not use parameters of bit length greater than 1.

[0265] The `nnpfc_num_parameters_idc` indicates the maximum number of neural network parameters for the NNPF in units of a power of 2048. `nnpfc_num_parameters_idc` equal to 0 indicates that the maximum number of neural network parameters is unknown. The value `nnpfc_num_parameters_idc` shall be in the range of 0 to 52, inclusive. Values of `nnpfc_num_parameters_idc` greater than 52 are reserved for future use by ITU-T|ISO/IEC and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore NNPFC SEI messages with `nnpfc_num_parameters_idc` greater than 52.

[0266] If the value of `nnpfc_num_parameters_idc` is greater than zero, the variable `maxNumParameters` is derived as follows:

[00009] $\text{maxNumParameters} = (2048 \ll \text{nnpfc_num_parameters_idc}) - 1$ [Equation9]

[0267] It is a requirement of bitstream conformance that the number of neural network parameters of the NNPF shall be less than or equal to `maxNumParameters`.

[0268] The `nnpfc_num_kmac_operations_idc` greater than 0 indicates that the maximum number of multiply-accumulate operations per sample of the NNPF is less than or equal to `nnpfc_num_kmac_operations_idc * 1000`. `nnpfc_num_kmac_operations_idc` equal to 0 indicates that the maximum number of multiply-accumulate operations of the network is unknown. The value of `nnpfc_num_kmac_operations_idc` shall be in the range of 0 to $2^{\text{sup.32-2}}$, inclusive.

[0269] The `nnpfc_total_kilobyte_size` greater than 0 indicates a total size in kilobytes required to store the uncompressed parameters for the neural network. The total size in bits is a number equal to or greater than the sum of bits used to store each parameter. `nnpfc_total_kilobyte_size` is the total size in bits divided by 8000, rounded up. `nnpfc_total_kilobyte_size` equal to 0 indicates that the total size required to store the parameters for the neural network is unknown. The value of `nnpfc_total_kilobyte_size` shall be in the range of 0 to $2^{\text{sup.32-2}}$, inclusive.

[0270] The `nnpfc_metadata_extension_num_bits` equal to 0 specifies that `nnpfc_reserved_metadata_extension` is not present. `nnpfc_metadata_extension_num_bits` greater than 0 specifies the length, in bits, of `nnpfc_reserved_metadata_extension`. `nnpfc_metadata_extension_num_bits` shall be equal to 0 in this edition of this document. Values in the range of 1 to 2048, inclusive, for `nnpfc_metadata_extension_num_bits` are reserved for future use by ITU-T|ISO/IEC and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall allow any value of `nnpfc_metadata_extension_num_bits` in the range of 0 to 2048, inclusive. Values of `nnpfc_metadata_extension_num_bits` greater than 2048 shall not be present in bitstreams conforming to this edition of this document and are not reserved for future use.

[0271] The `nnpfc_reserved_metadata_extension` shall not be present in bitstreams conforming to this edition of this document. However, decoders conforming to this edition of this document shall ignore the presence and value of `nnpfc_reserved_metadata_extension`. When present, the length, in bits, of `nnpfc_reserved_metadata_extension` is equal to `nnpfc_metadata_extension_num_bits`.

[0272] The `nnpfc_reserved_zero_bit_b` shall be equal to 0 in bitstreams conforming to this edition of this document. Decoders shall ignore NNPFC SEI messages in which `nnpfc_reserved_zero_bit_b` is not equal to 0.

[0273] The `nnpfc_payload_byte[i]` contains the *i*-th byte of a bitstream conforming to ISO/IEC 15938-17. The byte sequence `nnpfc_payload_byte[i]` for all present values of *i* shall be a complete bitstream that conforms to ISO/IEC 15938-17.

Neural-Network Post-Filter Activation SEI Message (NNPFA)

[0274] The syntax structure for NNPFA is shown in Table 20.

TABLE-US-00020 TABLE 20 `nn_post_filter_activation( payloadSize )` { Descriptor `nnpfa_target_id` `ue(v)` `nnpfa_cancel_flag`
`u(1)` `if( !nnpfa_cancel_flag )` { `nnpfa_target_base_flag` `u(1)` `nnpfa_persistence_flag` `u(1)`
`nnpfa_num_output_entries` `ue(v)` `for( i = 0; i < nnpfa_num_output_entries; i++ )` `nnpfa_output_flag[ i ]` `u(1)` } }

[0275] The NNPFA syntax structure of Table 20 can be signaled in the form of an SEI message. An SEI message signaling the NNPFA syntax structure of Table 19 can be referred to as an NNPFA SEI message.

[0276] The neural-network post-filter activation (NNPFA) SEI message activates or de-activates the possible use of the target neural-network post-processing filter (NNPF), identified by `nnpfa_target_id` and `nnpfa_target_base_flag`, for post-processing filtering of a set of pictures. For a particular picture for which the NNPF is activated, the target NNPF is derived as follows: [0277] If `nnpfa_target_base_flag` is equal to 1, the target NNPF is the base NNPF with `nnpfc_id` equal to `nnpfa_target_id`. [0278] Otherwise (`nnpfa_target_base_flag` is equal to 0), the target NNPF is the NNPF specified by the last NNPFC SEI message with `nnpfc_id` equal to `nnpfa_target_id` that precedes the first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message that contains the base NNPF.

[0279] There can be several NNPFA SEI messages present for the same picture, for example, when the NNPFs are meant for different purposes or for filtering of different colour components.

[0280] The `nnpfa_target_id` indicates the target NNPF, which is specified by one or more NNPFC SEI messages that pertain to the current picture and have `nnpfc_id` equal to `nnpfa_target_id`.

[0281] The value of `nnpfa_target_id` shall be in the range of 0 to $2^{\text{sup.32-2}}$, inclusive. `nnpfa_target_id` values in the range 256 to 511 and in the range $2^{\text{sup.31}}$ to $2^{\text{sup.32-2}}$ may be reserved for future use. Decoders must ignore NNPFA SEI messages with `nnpfa_target_id` in the range 256 to 511 or $2^{\text{sup.31}}$ to $2^{\text{sup.32-2}}$.

[0282] An NNPFA SEI message with a particular value of `nnpfa_target_id` shall not be present in a current PU unless one or both of the following conditions are true: [0283] Within the current CLVS there is an NNPFC SEI message with `nnpfc_id` equal to the particular value of `nnpfa_target_id` present in a PU preceding the current PU in decoding order. [0284] There is an NNPFC SEI message with `nnpfc_id` equal to the particular value of `nnpfa_target_id` in the current PU.

[0285] If a PU contains both an NNPFC SEI message with a particular value of `nnpfc_id` and an NNPFA SEI message with `nnpfa_target_id` equal to the particular value of `nnpfc_id`, the NNPFC SEI message shall precede the NNPFA SEI message in decoding order.

[0286] The `nnpfa_cancel_flag` equal to 1 indicates that the persistence of the target NNPFF established by any previous NNPFA SEI message with the same `nnpfa_target_id` as the current SEI message is cancelled, i.e., the target NNPFF is no longer used unless it is activated by another NNPFA SEI message with the same `nnpfa_target_id` as the current SEI message and `nnpfa_cancel_flag` equal to 0. `nnpfa_cancel_flag` equal to 0 indicates that the `nnpfa_target_base_flag`, `nnpfa_persistence_flag`, and `nnpfa_num_output_entries` follow.

[0287] The `nnpfa_target_base_flag` equal to 1 specifies that the target NNPFF is the base NNPFF with `nnpfc_id` equal to `nnpfa_target_id`. `nnpfa_target_base_flag` equal to 0 specifies that the target NNPFF is the NNPFF specified by the last NNPFC SEI message with `nnpfc_id` equal to `nnpfa_target_id` that precedes the first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message that contains the base NNPFF.

[0288] The `nnpfa_persistence_flag` specifies the persistence of the target NNPFF for the current layer. `nnpfa_persistence_flag` equal to 0 specifies that the target NNPFF may be used for post-processing filtering for the current picture only. `nnpfa_persistence_flag` equal to 1 specifies that the target NNPFF may be used for post-processing filtering for the current picture and all subsequent pictures of the current layer in output order until one or more of the following conditions are true: [0289] A new CLVS of the current layer begins.

[0290] The bitstream ends. [0291] A picture in the current layer associated with a NNPFA SEI message with the same `nnpfa_target_id` as the current SEI message and `nnpfa_cancel_flag` equal to 1 is output that follows the current picture in output order.

[0292] The target NNPFF is not applied for this subsequent picture in the current layer associated with a NNPFA SEI message with the same `nnpfa_target_id` as the current SEI message and `nnpfa_cancel_flag` equal to 1.

[0293] Let the `nnpfcTargetPictures` be the set of pictures to which the last NNPFC SEI message with `nnpfc_id` equal to `nnpfa_target_id` that precedes the current NNPFA SEI message in decoding order pertains. Let `nnpfaTargetPictures` be the set of pictures for which the target NNPFF is activated by the current NNPFA SEI message. It is a requirement of bitstream conformance that any picture included in `nnpfaTargetPictures` shall also be included in `nnpfcTargetPictures`.

[0294] The `nnpfa_num_output_entries` specifies the number of `nnpfa_output_flag[i]` syntax elements present in the NNPFA SEI message. The value of `nnpfa_num_output_entries` shall be in the range of 0 to `NumInpPicsInOutputTensor`, inclusive.

[0295] The `nnpfa_output_flag[i]` equal to 1 specifies that the NNPFF-generated picture that corresponds to the input picture having index `InpIdx[i]` is output by the NNPFF process activated by this NNPFA SEI message, where the NNPFF process is specified in the semantics of the NNPFC SEI message. `nnpfa_output_flag[i]` equal to 0 specifies that the NNPFF-generated picture that corresponds to the input picture having index `InpIdx[i]` is not output by the NNPFF process activated by this NNPFA SEI message. When `nnpfa_num_output_entries` is less than `NumInpPicsInOutputTensor`, `nnpfa_output_flag[i]` is inferred to be equal to 1 for each value of `i` in the range of `nnpfa_num_output_entries` to `NumInpPicsInOutputTensor-1`, inclusive.

Post-Filter Hint

[0296] The syntax structure for post-filter hints is shown in Table 21.

TABLE-US-00021 TABLE 21 `post_filter_hint( payloadSize )` { Descriptor `filter hint cancel_flag u(1)` if(`!filter_hint_cancel_flag`) { `filter hint persistence_flag u(1)` `filter hint size_y ue(v)` `filter hint size_x ue(v)` `filter_hint_type u(2)` `filter hint chroma_coeff_present_flag u(1)` for(`cIdx = 0; cIdx < filter_hint_chroma_coeff_present_flag ? 3 : 1`; `cIdx++`) for(`cy = 0; cy < filter_hint_size_y`; `cy++`) for(`cx = 0; cx < filter_hint_size_x`; `cx++`) `filter hint_value[ cIdx ][ cy ][ cx ] se(v)` } }

[0297] The post-filter hint syntax structure of Table 21 can be signaled in the form of an SEI message. An SEI message signaling the post-filter hint syntax structure of Table 21 may be referred to as a post-filter hint SEI message.

[0298] This SEI message provides the coefficients of a post-filter or correlation information for the design of a post-filter for potential use in post-processing of a set of pictures after they are decoded and output to obtain improved displayed quality.

[0299] The `filter_hint_cancel_flag` equal to 1 indicates that the SEI message cancels the persistence of any previous post-filter hint SEI message in output order that applies to the current layer. `filter_hint_cancel_flag` equal to 0 indicates that post-filter hint information follows.

[0300] The `filter_hint_persistence_flag` specifies the persistence of the post-filter hint SEI message for the current layer.

`filter_hint_persistence_flag` equal to 0 specifies that the post-filter hint applies to the current decoded picture only.

`filter_hint_persistence_flag` equal to 1 specifies that the post-filter hint SEI message applies to the current decoded picture and persists for all subsequent pictures of the current layer in output order until one or more of the following conditions are true: [0301] A new CLVS of the current layer begins. [0302] The bitstream ends. [0303] A picture in the current layer in an AU associated with a post-filter hint SEI message is output that follows the current picture in output order.

[0304] The `filter_hint_size_y` specifies the vertical size of the filter coefficient or correlation array. The value of `filter_hint_size_y` shall be in the range of 1 to 15, inclusive.

[0305] The `filter_hint_size_x` specifies the horizontal size of the filter coefficient or correlation array. The value of `filter_hint_size_x` shall be in the range of 1 to 15, inclusive.

[0306] The `filter_hint_type` identifies the type of the transmitted filter hints as specified in Table 19. The value of `filter_hint_type` shall be in the range of 0 to 2, inclusive. The value of `filter_hint_type` equal to 3 is reserved for future use and shall not be present in bitstreams conforming to this edition of this document. Decoders conforming to this edition of this document shall ignore post-filter hint SEI messages having `filter_hint_type` equal to 3.

TABLE-US-00022 TABLE 19 Value Description 0 Coefficients of a 2D-FIR filter 1 Coefficients of two 1D-FIR filters 2 Cross-correlation matrix

[0307] The `filter_hint_chroma_coeff_present_flag` equal to 1 specifies that filter coefficients for chroma are present.

`filter_hint_chroma_coeff_present_flag` equal to 0 specifies that filter coefficients for chroma are not present.

[0308] The `filter_hint_value[cIdx][cy][cx]` specifies a filter coefficient or an element of a cross-correlation matrix between the original and the decoded signal with 16-bit precision. The value of `filter_hint_value[cIdx][cy][cx]` shall be in the range of $-2.\text{sup.}31+1$ to $2.\text{sup.}31-1$, inclusive. `cIdx` specifies the related colour component, `cy` represents a counter in vertical direction and `cx` represents a

counter in horizontal direction. Depending on the value of filter_hint_type, the following applies: [0309] If filter_hint_type is equal to 0, the coefficients of a 2-dimensional finite impulse response (FIR) filter with the size of filter_hint_size_y*filter_hint_size_x are transmitted. [0310] Otherwise, if filter_hint_type is equal to 1, the filter coefficients of two 1-dimensional FIR filters are transmitted. In this case, filter_hint_size_y shall be equal to 2. The index cy equal to 0 specifies the filter coefficients of the horizontal filter and cy equal to 1 specifies the filter coefficients of the vertical filter. In the filtering process, the horizontal filter is applied first and the result is filtered by the vertical filter. [0311] Otherwise (filter_hint_type is equal to 2), the transmitted hints specify a cross-correlation matrix between the original signal s and the decoded signal s'.

[0312] The normalized cross-correlation matrix for a related colour component identified by cIdx with the size of filter_hint_size_y*filter_hint_size_x is defined as follows:

[00010]

$$\text{filter_hint_value}(cIdx, cy, cx) = \frac{1}{(2^{8+\text{bitDepth}} - 1)^{2*n*w}} \cdot \text{Math.}_{m=0}^{h-1} \cdot \text{Math.}_{n=0}^{w-1} s(m, n) * s'(m + cy - \text{OffsetY}, n + cx - \text{OffsetX}) \quad [\text{Equation10}]$$

where s denotes array of samples of the colour component cIdx of the original picture, s' denotes corresponding array of the decoded picture, h denotes the vertical height of the related colour component, w denotes the horizontal width of the related colour component, bitDepth denotes the bit depth of the colour component, OffsetY is equal to (filter_hint_size_y>>1), OffsetX is equal to (filter_hint_size_x>>1), 0<=cy<filter_hint_size_y and 0<=cx<filter_hint_size_x.

[0313] A decoder can derive a Wiener post-filter from the cross-correlation matrix of original and decoded signal and the auto-correlation matrix of the decoded signal.

Problems of Conventional Art

[0314] In the current design of neural-network post-filter characteristics (NNPFCs) and neural-network post-filter activation supplemental enhancement information (SEI) messages, an NNPFC SEI message can activate a base filter (i.e., an NNPFC SEI message with nnpfc_base_flag equal to 1) or an update filter (i.e., an NNPFC SEI message with nnpfc_base_flag equal to 0) based on nnpfa_target_base_flag.

[0315] The following problems exist in identifying a target NNPFC. FIG. 6 is a diagram illustrating a problematic situation that may occur when a target NNPFC to be activated is identified on the basis of a neural-network post-filter activation (NNPFA) SEI message.

[0316] When the value of nnpfa_target_base_flag is 0, there are two conflicting specifications to define which NNPFC will be activated. [0317] As shown in Table 23, at the beginning of the semantics for NNPFA, the following is specified: Otherwise (nnpfa_target_base_flag is 0), the target NNPFC is the NNPFC specified by the last NNPFC SEI message with nnpfc_id equal to nnpfa_target_id that precedes the first video coding layer (VCL) network abstract layer (NAL) unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message containing the base NNPFC.

TABLE-US-00023 TABLE 23 Otherwise (nnpfa_target_base_flag is equal to 0), the target NNPFC is the NNPFC specified by the last NNPFC SEI message with nnpfc_id equal to nnpfa_target_id that precedes the first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message that contains the base NNPFC [0318] As shown in Table 24, in the second half of the semantics of nnpfa_target_base_flag itself, the following is specified: nnpfa_target_base_flag equal to 0 specifies that the target NNPFC is the NNPFC specified by the last NNPFC SEI message with nnpfc_id equal to nnpfa_target_id that precedes the first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message containing the base NNPFC.

TABLE-US-00024 TABLE 24 nnpfa_target_base_flag equal to 0 specifies that the target NNPFC is the NNPFC specified by the last NNPFC SEI message with nnpfc_id equal to nnpfa_target_id that precedes the first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message that contains the base NNPFC.

[0319] When nnpfa_target_base_flag is 0 but there is no update of the NNPFC SEI with nnpfc_id equal to nnpfa_target_id of the target NNPFC, it is unclear whether a decoder should activate the base filter. This may occur in the example of FIG. 6. In the example of FIG. 6, an NNPFA SEI message exists in an access unit (AU) including a predictor (PU) with a picture order count of 3 (POC3), the corresponding NNPFA SEI message has a specific nnpfa_target_id value, and the value of nnpfa_target_base_flag is 0.

nnpfa_target_base_flag having a value of 0 represents that the target NNPFC is not a base NNPFC but rather an updated NNPFC.

[0320] Specifically, the target NNPFC activated by the NNPFA SEI message is an NNPFC specified by the last NNPFC SEI message with nnpfc_id equal to nnpfa_target_id that precedes the first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message containing the base NNPFC. However, as shown in the example of FIG. 6, when there is no update of the NNPFC SEI message with nnpfc_id equal to nnpfa_target_id, it is unclear whether to activate the base NNPFC regardless of the fact that the value of nnpfa_target_base_flag is equal to 0.

EMBODIMENTS

[0321] The following embodiments provide solutions to the above-described problems. The outlines of the embodiments are given below. [0322] 1. It is constrained that, when the value of nnpfa_target_base_flag is equal to 0 in an NNPFA SEI message, there should be at least one NNPFC SEI message with nnpfc_id equal to nnpfa_target_id and nnpfc_base_flag equal to 0 that precedes the NNPFA SEI message in decoding order. [0323] 2. Alternatively, it may be clarified or specified that, when nnpfa_target_base_flag is equal to 0, the target NNPFC may be a base NNPFC in the case where there is no NNPFC SEI message with nnpfc_id equal to nnpfa_target_id and nnpfa_base_flag equal to 0 that precedes the NNPFA SEI message in decoding order.

[0324] The present invention proposes various embodiments to address the above-described problems. The embodiments proposed in the present invention may be performed individually or in a combination of two or more.

[0325] Hereinafter, an NNPFC may be the NNPFC syntax structures of Tables 1 to 3 above and signaled in the form of an SEI message. In this case, the NNPFC may be an NNPFC SEI message. An NNPFA may be the NNPFA syntax structure of Table 20 above and signaled in the form of an SEI message. In this case, the NNPFA may be an NNPFA SEI message. A post-filter hint may be the post-filter hint syntax structure of Table 21 above and may be signaled in the form of an SEI message. In this case, a post-filter hint may be a post-filter hint SEI message.

Embodiment 1

[0326] Embodiment 1 relates to the above description of outline 1. According to embodiment 1, when the value of nnpfa_target_base_flag is equal to 0 in an NNPFA SEI message, at least one NNPFC SEI message with nnpfc_id equal to

nnpfa_target_id and nnpfc_base_flag equal to 0 should precede the NNPFA SEI message in decoding order. For example, based on the fact that the value of nnpfa_target_base_flag is equal to 0 in an NNPFA SEI message, at least one NNPFC SEI message with nnpfc_id equal to nnpfa_target_id and nnpfc_base_flag equal to 0 is encoded to precede the NNPFA SEI message in decoding order. In embodiment 1, a target NNPFA for a specific picture for which an NNPFA is activated may be derived as follows.

[0327] nnpfa_target_base_flag being equal to 1 represents that the target NNPFA is a base NNPFA with nnpfc_id equal to nnpfa_target_id. nnpfa_target_base_flag being equal to 0 does not represent that the target NNPFA is a base NNPFA, but represents that the target NNPFA is an NNPFA specified by the last NNPFC SEI message with nnpfc_id equal to nnpfa_target_id that precedes the first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message containing the base NNPFA. When nnpfa_target_base_flag is equal to 0, there is at least one NNPFC SEI with nnpfc_id equal to nnpfa_target_id and nnpfa_base_flag equal to 0 that precedes the NNPFA SEI message in decoding order. Therefore, when nnpfa_target_base_flag is equal to 0, there is an updated NNPFA specified by the NNPFC SEI message preceding the NNPFA SEI (in decoding order), and it is possible to activate the updated NNPFA without uncertainty about whether to activate the base NNPFA.

[0328] FIG. 7 is an example of a case to which an embodiment of the present invention is applied.

[0329] The example of FIG. 7 shows a case where there is an NNPFA SEI message in an AU including a PU with POC3, the corresponding NNPFA SEI message has a specific nnpfa_target_id value, and the value of nnpfa_target_base_flag is 0.

nnpfa_target_base_flag having a value of 0 represents that the target NNPFA is not a base NNPFA but rather an updated NNPFA.

[0330] In this case, according to embodiment 1, there is at least one NNPFC SEI message with nnpfc_id equal to nnpfa_target_id and nnpfa_base_flag equal to 0 that precedes the NNPFA SEI message in decoding order as shown in FIG. 7. Therefore, since an updated NNPFA is specified by the NNPFC SEI message preceding the NNPFA SEI message (in decoding order), the target NNPFA activated by the NNPFA SEI message may be determined as the updated NNPFA.

Embodiment 2

[0331] Embodiment 2 relates to the above description of outline 2. According to embodiment 2, when nnpfa_target_base_flag is equal to 0 and no NNPFC SEI message with nnpfc_id equal to nnpfa_target_id and nnpfc_base_flag equal to 0 precedes the NNPFA SEI message in decoding order, the target NNPFA can be a base NNPFA. For example, when nnpfa_target_base_flag is equal to 0 and no NNPFC SEI message with nnpfc_id equal to nnpfa_target_id and nnpfc_base_flag equal to 0 precedes the NNPFA SEI message in decoding order, it may be clarified or specified that the target NNPFA is determined as a base NNPFA. In embodiment 2, a target NNPFA for a specific picture for which an NNPFA is activated may be derived as follows.

[0332] nnpfa_target_base_flag being equal to 1 represents that the target NNPFA is a base NNPFA with nnpfc_id equal to nnpfa_target_id. nnpfa_target_base_flag being equal to 0 does not represent that the target NNPFA is a base NNPFA, but represents that the target NNPFA is an NNPFA specified by the last NNPFC SEI message with nnpfc_id equal to nnpfa_target_id that precedes the first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message containing the base NNPFA.

[0333] When nnpfa_target_base_flag is equal to 0 and there is no NNPFC SEI message with nnpfc_id equal to nnpfa_target_id and nnpfa_base_flag equal to 0 that precedes the NNPFA SEI message in decoding order, the target NNPFA may be determined as a base NNPFA. Therefore, when nnpfa_target_base_flag has a value of 0 but there is no updated NNPFA to be activated, it is possible to determine the base NNPFA as the target NNPFA without uncertainty about a target to be activated.

[0334] FIG. 8 is another example of a case to which an embodiment of the present invention is applied.

[0335] The example of FIG. 8 shows a case where there is an NNPFA SEI message in a PU with POC3, the corresponding NNPFA SEI message has a specific nnpfa_target_id value, and the value of nnpfa_target_base_flag is 0. nnpfa_target_base_flag having a value of 0 represents that the target NNPFA is not a base NNPFA but rather an updated NNPFA.

[0336] In this case, when no NNPFC SEI message with nnpfc_id equal to nnpfa_target_id and nnpfa_base_flag equal to 0 precedes the NNPFA SEI message in decoding order as shown in FIG. 8, a base NNPFA may be determined as the target NNPFA to be activated by the NNPFA SEI message according to embodiment 2.

Image Encoding Method and Image Decoding Method

[0337] An image encoding method and an image decoding method according to embodiments of the present invention will be described below.

[0338] FIG. 9 is an example of an image encoding method to which embodiments of the present disclosure are applicable, and FIG. 10 is an example of an image decoding method to which embodiments of the present disclosure are applicable.

[0339] Referring to FIG. 9, at least one neural network that may be used as a postprocessing filter may be determined, and information on the determined neural network may be encoded as at least one NNPFC SEI message (S610).

[0340] It may be determined whether to activate a target NNPFA that is applicable to a current picture, and information on the determined target NNPFA may be encoded as an NNPFA SEI message (S620). The process S620 of determining whether to activate the target NNPFA may include a process of determining a target NNPFA, a process of determining whether to cancel the persistence of the target NNPFA, a process of determining whether the target NNPFA persists, a process of determining whether to apply a base NNPFA, and the like.

[0341] Post-filter coefficients, correlation information, or the like for the design of a post-filter may be encoded as a post-filter hint SEI message (S630). The NNPFC SEI message, the NNPFA SEI message, and/or the post-filter hint SEI message may be included in an NNPFA SEI message.

[0342] The target NNPFA may be determined or activated by various embodiments of the present invention when the NNPFA SEI message is applied to the current picture in the image decoding apparatus 300.

[0343] For example, which NNPFA will be activated may be determined on the basis of the NNPFA SEI message. Here, the target NNPFA to be activated may be identified from target identification information and target base flag information included in the NNPFA SEI message. For example, whether to activate the base NNPFA or an updated NNPFA may be determined on the basis of the NNPFA SEI message. As a specific example, whether to activate the base NNPFA or the updated NNPFA may be determined on the basis of the target base flag information included in the NNPFA SEI message.

[0344] For example, the target identification information may be information corresponding to nnpfa_target_id indicating a target neural network postprocessing filter designated by one or more NNPFC SEI messages which are related to the current picture and have the same identification information nnpfc_id as the target identification information. The base flag information may be

information corresponding to `nnpfc_base_flag` indicating whether an NNPF designated by the NNPF SEI message is a base NNPF, and the target base flag information may be information corresponding to `nnpfa_target_base_flag` indicating whether the target NNPF is a base NNPF having identification information identical to the target identification information.

[0345] Referring to FIG. 10, an SEI message for an NNPF to be applied to a current picture may be acquired from a bitstream. The SEI message for the NNPF may include an NNPF SEI message, an NNPF SEI message, and/or a post-filter hint SEI message.

[0346] When the SEI message for the NNPF is applied to the current picture, at least one neural network that may be used as a postprocessing filter may be determined on the basis of at least one NNPF SEI message included in the SEI message for the NNPF (S710).

[0347] Whether to activate a target NNPF that may be applied to the current picture may be determined on the basis of at least one NNPF SEI message acquired from the bitstream (S720). The process S720 of determining whether to activate a target NNPF may include a process of determining a target NNPF, a process of determining whether to cancel the persistence of the target NNPF, a process of determining whether the target NNPF persists, a process of determining whether to apply a base NNPF, and the like.

[0348] When the target NNPF is activated (either through determination or persistence), a target neural network postprocessing filter may be applied to the current picture (S730).

[0349] Various embodiments of the present invention can be utilized to determine or activate the target NNPF.

[0350] For example, which NNPF will be activated may be determined on the basis of the NNPF SEI message. Here, the target NNPF to be activated may be identified from target identification information and target base flag information included in the NNPF SEI message. For example, whether to activate the base NNPF or an updated NNPF may be determined on the basis of the NNPF SEI message. As a specific example, whether to activate the base NNPF or the updated NNPF may be determined on the basis of the target base flag information included in the NNPF SEI message.

[0351] FIG. 11 shows a process of determining a target NNPF according to an embodiment of the present disclosure. For example, the process shown in FIG. 11 may be performed by an image decoding apparatus.

[0352] Referring to FIG. 11, target identification information and target base flag information of an NNPF SEI message are acquired (S1110). For example, the target identification information and the target base flag information of the NNPF SEI message may be acquired from a bitstream.

[0353] For example, the target identification information of the NNPF SEI message may be information indicating a target neural network postprocessing filter designated by one or more NNPF SEI messages which are related to a current picture and have identification information identical to the target identification information. The target base flag information may be information indicating whether a target NNPF is a base NNPF having identification information identical to the target identification information.

[0354] Also, for example, when the target base flag information of the NNPF SEI message has a value of 1, this may represent that the target NNPF is the base NNPF. When the target base flag information of the NNPF SEI message has a value of 0, this may represent that the target NNPF is not the base NNPF. For example, when the value of the target base flag information is 0, this may represent that the target NNPF is an updated NNPF.

[0355] Based on the target base flag information indicating the base NNPF (YES in S1120), that is, based on the value of the target base flag information being equal to 1, the base NNPF may be determined as the target NNPF (S1130).

[0356] Based on the target base flag information not indicating the base NNPF (NO in S1120), that is, based on the value of the target base flag information being equal to 0, the target NNPF may be determined by an NNPF SEI message that precedes the NNPF SEI message in decoding order, has the same identification information as the NNPF SEI message, and has base flag information not indicating the base NNPF (S1140).

[0357] To this end, based on the target base flag information of the NNPF SEI message not indicating the base NNPF, there is an NNPF SEI message that has the same identification information as the NNPF SEI message and has base flag information not indicating the base NNPF, that is, the value of base flag information equal to 0, prior to the NNPF SEI message in decoding order. For example, prior to the NNPF SEI message with the value of the target base flag information equal to 0 (in decoding order), the image encoding apparatus 200 may encode an NNPF SEI message that has the same identification information as the NNPF SEI message and has base flag information not indicating the base NNPF, that is, the value of base flag information equal to 0.

[0358] FIG. 12 shows a process of determining a target NNPF according to an embodiment of the present disclosure. For example, the process shown in FIG. 12 may be performed by an image decoding device.

[0359] Referring to FIG. 12, target identification information and target base flag information of an NNPF SEI message are acquired (S1210). For example, the target identification information and the target base flag information of the NNPF SEI message may be acquired from a bitstream.

[0360] For example, the target identification information of the NNPF SEI message may be information indicating a target neural network postprocessing filter designated by one or more NNPF SEI messages which are related to a current picture and have identification information identical to the target identification information. The target base flag information may be information indicating whether a target NNPF is a base NNPF having identification information identical to the target identification information.

[0361] Also, for example, when the target base flag information of the NNPF SEI message has a value of 1, this may represent that the target NNPF is the base NNPF. When the target base flag information of the NNPF SEI message has a value of 0, this may represent that the target NNPF is not the base NNPF. As a specific example, this may represent that the target NNPF is an updated NNPF.

[0362] Based on the target base flag information indicating the base NNPF (YES in S1220), that is, based on the value of the target base flag information being equal to 1, the base NNPF may be determined as the target NNPF (S1240).

[0363] Based on the target base flag information not indicating the base NNPF (NO in S1220), that is, based on the value of the target base flag information being equal to 0, it is determined whether there is an NNPF SEI message that precedes the NNPF SEI message in decoding order, has the same identification information as the NNPF SEI message, and has base flag information not indicating the base NNPF (S1230).

[0364] Based on the existence of the NNPF SEI message satisfying the conditions (YES in S1230), an NNPF specified by the NNPF SEI message may be determined as the target NNPF (S1230).

[0365] Based on the absence of the NNPF SEI message satisfying the conditions (No in S1230), the base NNPF may be determined

as the target NNPF (S1240).

[0366] According to the above-described embodiments, it is possible to clearly determine a filter to be activated between a base filter and an updated filter.

[0367] In addition, according to the above-described embodiments, it is possible to prevent occurrence of a situation where it is unclear whether to activate a base filter or an updated filter.

[0368] FIG. 13 is a diagram exemplifying a content streaming system to which an embodiment according to the present disclosure can be applied.

[0369] Referring to FIG. 13, the content streaming system to which the embodiment(s) of the present document is applied may largely include an encoding server, a streaming server, a web server, a media storage, a user device, and a multimedia input device.

[0370] The encoding server compresses content input from multimedia input devices such as a smartphone, a camera, a camcorder, etc. into digital data to generate a bitstream and transmit the bitstream to the streaming server. As another example, when the multimedia input devices such as smartphones, cameras, camcorders, etc. directly generate a bitstream, the encoding server may be omitted.

[0371] The bitstream may be generated by an encoding method or a bitstream generating method to which the embodiment(s) of the present document is applied, and the streaming server may temporarily store the bitstream in the process of transmitting or receiving the bitstream.

[0372] The streaming server transmits the multimedia data to the user device based on a user's request through the web server, and the web server serves as a medium for informing the user of a service. When the user requests a desired service from the web server, the web server delivers it to a streaming server, and the streaming server transmits multimedia data to the user. In this case, the content streaming system may include a separate control server. In this case, the control server serves to control a command/response between devices in the content streaming system.

[0373] The streaming server may receive content from a media storage and/or an encoding server. For example, when the content is received from the encoding server, the content may be received in real time. In this case, in order to provide a smooth streaming service, the streaming server may store the bitstream for a predetermined time.

[0374] Examples of the user device may include a mobile phone, a smartphone, a laptop computer, a digital broadcasting terminal, a personal digital assistant (PDA), a portable multimedia player (PMP), navigation, a slate PC, tablet PCs, ultrabooks, wearable devices (ex. smartwatches, smart glasses, head mounted displays), digital TVs, desktops computer, digital signage, and the like.

[0375] Each server in the content streaming system may be operated as a distributed server, in which case data received from each server may be distributed.

[0376] The scope of the present disclosure includes software or machine-executable instructions (e.g., an operating system, an application, firmware, a program, etc.) that cause operations according to various embodiments of the present disclosure to be executed on a device or a computer, and a non-transitory computer-readable medium having such software or instructions stored thereon and being executable on the device or the computer.

[0377] The embodiment according to the present disclosure can be used to encode/decode images.

Claims

1. An image decoding method performed by an image decoding apparatus, the method comprising: obtaining a neural-network post-filter characteristics (NNPFC) supplemental enhancement information (SEI) message and a neural-network post-filter activation (NNPFA) SEI message; determining at least one neural-network to be used as a neural-network post-filter (NNPF) based on the NNPFC SEI message; and determining whether activating a target NNPF to be applied to a current picture or not based on the NNPFA SEI message, wherein the NNPFA SEI message includes target identification information and target base flag information, wherein the target NNPF is determined based on the target identification information and the target base flag information, wherein based on the target base flag information not indicating that the target NNPF is a base NNPF, there is at least one NNPFC SEI message, that precedes the NNPFA SEI message in decoding order, with identification information equal to the target identification information and base flag information having a value equal to a value of the target base flag information.
2. The image decoding method of claim 1, wherein the target base flag information having a value of 1 indicates that the target NNPF is the base NNPF with the identification information equal to the target identification information.
3. The image decoding method of claim 1, wherein the target base flag information having a value of 0 indicates that the target NNPF is a NNPF specified by the NNPFC SEI message with the identification information equal to the target identification information, Wherein the NNPF SEI message with the identification information equal to the target identification information is a last NNPF SEI message that precedes a first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message that contains the base NNPF.
4. An image encoding method performed by an encoding apparatus, the image encoding method comprising: encoding at least one neural-network that can be used as a post-processing filter into a neural-network post-filter characteristics (NNPFC) SEI message; and encoding whether a target NNPF that can be applied to the current picture is activated into a neural-network post-filter activation (NNPFA) SEI message, wherein the NNPFA SEI message includes target identification information and target base flag information, wherein based on the target base flag information not indicating that the target NNPF is a base NNPF, there is at least one NNPFC SEI message, that precedes the NNPFA SEI message in decoding order, with identification information equal to the target identification information and base flag information having a value equal to a value of the target base flag information.
5. The image encoding method of claim 4, wherein the target base flag information having a value of 1 indicates that the target NNPF is the base NNPF with the identification information equal to the target identification information.
6. The image encoding method of claim 4, wherein the target base flag information having a value of 0 indicates that the target NNPF is a NNPF specified by the NNPFC SEI message with the identification information equal to the target identification information, Wherein the NNPF SEI message with the identification information equal to the target identification information is a last NNPF SEI message that precedes a first VCL NAL unit of the current picture in decoding order and is not a repetition of the NNPFC SEI message that contains the base NNPF.

7. A method of transmitting data of an image, the method comprising: generating a bitstream of the image, the bitstream is generated by encoding at least one neural-network that can be used as a post-processing filter into a neural-network post-filter characteristics (NNPFC) SEI message and encoding whether a target NNPF that can be applied to the current picture is activated into a neural-network post-filter activation (NNPFA) SEI message; and transmitting the data including the bitstream, wherein the NNPFA SEI message includes target identification information and target base flag information, wherein based on the target base flag information not indicating that the target NNPF is a base NNPF, there is at least one NNPFC SEI message, that precedes the NNPFA SEI message in decoding order, with identification information equal to the target identification information and base flag information having a value equal to a value of the target base flag information.
