WINDING TYPE ELECTRODE ASSEMBLY, BATTERY CELL, BATTERY AND POWER CONSUMPTION DEVICE

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation of U.S. patent application Ser. No. 17/547,535 filed on Dec. 10, 2021, which is a continuation of International Application No. PCT/CN2021/079604, filed on Mar. 8, 2021, the disclosure of which is hereby incorporated by reference in its entirety.

TECHNICAL FIELD

The present application relates to the technical field of batteries, and particularly relates to a winding type electrode assembly, a battery cell, a battery, a power consumption device and a method and a device for manufacturing an electrode assembly.

BACKGROUND

Lithium ion batteries have become mainstream products of secondary batteries due to their outstanding advantages such as high energy density and good cycle performance. Besides, they are widely used in portable electrical appliances, power vehicles, mobile phones, spacecraft and other fields.

Graphite or silicon is commonly used as a negative material of a battery. Because its lithiation electric potential is close to that of metallic lithium, the phenomenon of lithium plating is likely to occur under certain conditions, which seriously affects cycle performance of the lithium ion batteries. Even in serious cases, it may cause safety problems such as short circuit in the battery due to lithium dendrites formed by the lithium plating.

SUMMARY

The embodiments of the present application provide a winding type electrode assembly, a battery cell, a battery, a power consumption device and a method and an apparatus for manufacturing an electrode assembly, thus solving a problem of lithium plating of a battery.

In a first aspect, the embodiments of the present application provide a winding type electrode assembly, which includes a positive electrode plate and a negative electrode plate, where the positive electrode plate includes a first positive winding end portion and a positive winding middle section connected to each other; the negative electrode plate includes a first portion and a second portion connected to each other, the first portion is arranged opposite to the first positive winding end portion, and the second portion is arranged opposite to the positive winding middle section; and in a winding axial direction of the winding type electrode assembly, a negative active material layer of the negative electrode plate exceeds a positive active material layer of the positive electrode plate, a maximum width of a negative active material layer of the first portion is $H1$, a minimum width of a positive active material layer of the first positive winding end portion is $L1$, a maximum width of a negative active material layer of the second portion is $H2$, a minimum width of a positive active material layer of the positive winding middle section is $L2$, and $H1-L1>H2-L2$.

In the above technical solution, a width difference between the maximum width of the negative active material

layer of the first portion and the minimum width of the positive active material layer of the first positive winding end portion is set to be larger than a width difference between the maximum width of the negative active material layer of the second portion and the minimum width of the positive active material layer of the positive winding middle section, that is, a maximum width difference between the positive active material layer of the first positive winding end portion and the negative active material layer of the first portion is larger than a maximum width difference between the negative active material layer of the second portion and the positive active material layer of the positive winding middle section, so that the risk of the lithium plating caused by the reason that a size of a part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet a design requirement is reduced.

In some embodiments of the first aspect of the present application, $H1>H2$.

In the above technical solution, due to the reason that the first portion is arranged opposite to the first positive winding end portion and the second portion is arranged opposite to the positive winding middle section, the maximum width of the negative active material layer of the first portion is larger than the maximum width of the negative active material layer of the second portion, which means that a width of the negative active material layer of the first portion is increased compared with that of the negative active material layer of the second portion, so that on the premise of guaranteeing energy density, the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement may be reduced.

In some embodiments of the first aspect of the present application, a minimum width of the negative active material layer of the first portion is $H3$, where $H3\geq H2$.

In the above technical solution, the minimum width of the negative active material layer of the first portion is not less than the maximum width of the negative active material layer of the second portion, so that the problem of the lithium plating caused by the reason that a size of a part, exceeding the positive active material layer of the first positive winding end portion in the winding axial direction, of the negative active material layer of the first portion does not meet the design requirement is avoided.

In some embodiments of the first aspect of the present application, $0.3\text{ mm}\leq H1-H2\leq 3\text{ mm}$.

In the above technical solution, in the winding axial direction, if the width of the negative active material layer of the first portion is too large, it is possible that the width exceeds a width of a separator film and the negative active material layer further interferes with a top cover assembly, increasing the short circuit risk. If the width of the negative active material layer of the first portion is not enough, the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate cannot meet the design requirement. Therefore, $0.3\text{ mm}\leq H1-H2\leq 3\text{ mm}$ may guarantee use safety of the winding type electrode assembly and further reduce the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the

3

negative active material layer of the negative electrode plate does not meet the design requirement.

In some embodiments of the first aspect of the present application, in the winding axial direction, one end of the negative active material layer of the first portion at least partially exceeds a corresponding end of the negative active material layer of the second portion, and the other end of the negative active material layer of the first portion is flush with the other end of the negative active material layer of the second portion.

In the above technical solution, in the winding axial direction, one end of the negative active material layer of the first portion at least partially exceeds the corresponding end of the negative active material layer of the second portion, and the other end of the negative active material layer of the first portion is flush with the other end of the negative active material layer of the second portion, so that the negative active material layer of the first portion is widened from one side in the winding axial direction compared with the negative active material layer of the second portion, a forming mode of the negative electrode plate is simple, and processing difficulty is reduced.

In some embodiments of the first aspect of the present application, the negative electrode plate further includes a negative tab, in the winding axial direction, the negative tab is located at one end of the negative electrode plate, and one end of the negative active material layer of the first portion close to the negative tab at least partially exceeds a corresponding end of the negative active material layer of the second portion.

In the above technical solution, in the winding axial direction, one end of the negative active material layer of the first portion close to the negative tab at least partially exceeds the corresponding end of the negative active material layer of the second portion, so that in a process of forming the negative tab through die cutting, the negative electrode plate with a width difference between the negative active material layer of the first portion and the negative active material layer of the second portion may be formed, that is, the negative electrode plate with the width difference between the negative active material layer of the first portion and the negative active material layer of the second portion may be formed by using an original forming process of the negative electrode plate.

In some embodiments of the first aspect of the present application, the negative electrode plate further includes a negative tab, in the winding axial direction, the negative tab is located at one end of the negative electrode plate, one end of the first portion close to the negative tab exceeds a corresponding end of the second portion, and the other end of the first portion is flush with the other end of the second portion.

In the above technical solution, in the winding axial direction, the end of the first portion close to the negative tab exceeds the corresponding end of the second portion, and the other end of the first portion is flush with the other end of the second portion, so that in the process of forming the negative tab through the die cutting, the negative electrode plate with a width difference between the first portion and the second portion may be formed, that is, the negative electrode plate with the width difference between the first portion and the second portion may be formed by using the original forming process of the negative electrode plate.

In some embodiments of the first aspect of the present application, in a winding direction, the first portion is provided with a connection surface connected to the second portion; and negative tabs are multiple in quantity, one of the

4

multiple negative tabs protrudes out of the first portion in the winding axial direction and is provided with a first side face close to the second portion, and the first side face and the connection surface are coplanar.

In the above technical solution, if the connection surface of the first portion and one side face of the negative tab are coplanar, the connection surface is not located between the two negative tabs, so that a situation that a connection position of the first portion and the second portion warps and then punctures the separator film due to the width difference between the first portion and the second portion during and after winding may be avoided.

In some embodiments of the first aspect of the present application, in the winding axial direction, the negative tab protruding out of the first portion is provided with a negative active material layer, and the negative active material layer on the negative tab protruding out of the first portion is connected to the negative active material layer of the first portion.

In the above technical solution, the negative active material layer on the negative tab protruding out of the first portion is connected to the negative active material layer of the first portion, which means that a width of a negative active material layer at part position of the first portion is further increased, so that the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement may be further reduced.

In some embodiments of the first aspect of the present application, the winding type electrode assembly includes a straight area and two bent areas, and the two bent areas are connected to two ends of the straight area respectively; and the first portion passes through the straight area at least two times.

In the above technical solution, after the first portion passes through the straight area two times, a possibility of relative deviation between the first positive winding end portion and the first portion is small, so the first portion passes through the straight area at least two times, which may reduce the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement due to the relative deviation between the first positive winding end portion and the first portion as much as possible.

In some embodiments of the first aspect of the present application, the positive electrode plate further includes a second positive winding end portion, and the first positive winding end portion and the second positive winding end portion are connected to two ends of the positive winding middle section respectively; the negative electrode plate further includes a third portion, the first portion and the third portion are connected to two ends of the second portion respectively, and the third portion is arranged opposite to the second positive winding end portion; and a maximum width of a negative active material layer of the third portion is $H4$, a minimum width of a positive active material layer of the second positive winding end portion is $L3$, and $H4-L3>H2-L2$.

In the above technical solution, the positive electrode plate further includes the second positive winding end portion, the negative electrode plate further includes the third portion, and the second positive winding end portion is

5

arranged opposite to the third portion. The maximum width difference between the positive active material layer of the first positive winding end portion and the negative active material layer of the first portion is larger than the maximum width difference between the negative active material layer of the second portion and the positive active material layer of the positive winding middle section, and a maximum width difference between the positive active material layer of the second positive winding end portion and the negative active material layer of the third portion is larger than a maximum width difference between the negative active material layer of the second portion and the positive active material layer of the positive winding middle section, so that the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement may be reduced.

In some embodiments of the first aspect of the present application, $H4 > H2$.

In the above technical solution, due to the reason that the third portion is arranged opposite to the second positive winding end portion and the second portion is arranged opposite to the positive winding middle section, the maximum width of the negative active material layer of the third portion is larger than the maximum width of the negative active material layer of the second portion, which means that a width of the negative active material layer of the third portion is increased compared with the negative active material layer of the second portion, so that on the premise of guaranteeing the energy density, the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement may be reduced.

In some embodiments of the first aspect of the present application, a minimum width of the negative active material layer of the third portion is $H5$, where $H5 \geq H2$.

In the above technical solution, the minimum width of the negative active material layer of the third portion is not less than the maximum width of the negative active material layer of the second portion, so that the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement is reduced.

In some embodiments of the first aspect of the present application, a maximum width of the positive active material layer of the first positive winding end portion is $L4$, a maximum width of the positive active material layer of the positive winding middle section is $L5$, and $L4 < L5$.

In the above technical solution, the maximum width of the positive active material layer of the first positive winding end portion is less than the maximum width of the positive active material layer of the positive winding middle section, so that the maximum width difference between the positive active material layer of the first positive winding end portion and the negative active material layer of the first portion is larger than the maximum width difference between the negative active material layer of the second portion and the positive active material layer of the positive winding middle section, and by changing a width of the first positive winding end portion of the positive electrode plate, a possibility of the lithium plating caused by the reason that the size of the

6

part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement is reduced.

In some embodiments of the first aspect of the present application, in the winding axial direction, one end of the positive active material layer of the positive winding middle section at least partially exceeds a corresponding end of the positive active material layer of the first positive winding end portion, and the other end of the positive active material layer of the positive winding middle section is flush with the other end of the positive active material layer of the first positive winding end portion.

In the above technical solution, in the winding axial direction, one end of the positive active material layer of the positive winding middle section at least partially exceeds the corresponding end of the positive active material layer of the first positive winding end portion, and the other end of the positive active material layer of the positive winding middle section is flush with the other end of the positive active material layer of the first positive winding end portion, so that the positive active material layer of the first positive winding end portion is widened from one side in the winding axial direction compared with the positive active material layer of the positive winding middle section, a forming mode of the positive electrode plate is simple, and processing difficulty is reduced.

In some embodiments of the first aspect of the present application, the positive electrode plate further includes a positive tab, in the winding axial direction, the positive tab is located at one end of the positive electrode plate, and one end of the positive active material layer of the positive winding middle section close to the positive tab at least partially exceeds a corresponding end of the positive active material layer of the first positive winding end portion.

In the above technical solution, one end of the positive active material layer of the positive winding middle section, close to the positive tab at least partially exceeds the corresponding end of the positive active material layer of the first positive winding end portion, so that in a process of forming the positive tab through die cutting, the positive electrode plate with a width difference between the positive active material layer of the first positive winding end portion and the positive active material layer of the positive winding middle section may be formed, that is, the positive electrode plate with the width difference between the positive active material layer of the first positive winding end portion and the positive active material layer of the positive winding middle section may be formed by using an original forming process of the positive electrode plate.

In a second aspect, the embodiments of the present application provide a battery cell, which includes the winding type electrode assembly provided according to any one of the embodiments of the first aspect.

In the above technical solution, the battery cell includes the winding type electrode assembly provided by any one of the embodiments of the first aspect, and a possibility of lithium plating of the battery cell caused by the reason that a size of a part, exceeding a positive active material layer of a positive electrode plate in a winding axial direction, of a negative active material layer of a negative electrode plate does not meet a design requirement is low.

In a third aspect, the embodiments of the present application provide a battery, which includes the battery cell provided by the embodiments of the second aspect.

In the above technical solution, the battery includes the battery cell provided by the embodiments of the second

aspect, and a possibility of lithium plating of the battery caused by the reason that a size of a part, exceeding a positive active material layer of a positive electrode plate in a winding axial direction, of a negative active material layer of a negative electrode plate does not meet a design requirement is low.

In a fourth aspect, the embodiments of the present application provide a power consumption device, which includes the battery cell provided according to the embodiments of the second aspect.

In the above technical solution, the power consumption device includes the battery cell provided by the embodiments of the second aspect, and a possibility of lithium plating of the battery cell of the power consumption device caused by the reason that a size of a part, exceeding a positive active material layer of a positive electrode plate in a winding axial direction, of a negative active material layer of a negative electrode plate does not meet a design requirement is low.

In a fifth aspect, the embodiments of the present application provide a method for manufacturing a winding type electrode assembly, which includes: providing a positive electrode plate, the positive electrode plate including: a first positive winding end portion and a positive winding middle section connected to each other; providing a negative electrode plate, the negative electrode plate including: a first portion and a second portion connected to each other; and winding the positive electrode plate and the negative electrode plate to form the winding type electrode assembly, so as to enable the first portion to be arranged opposite to the first positive winding end portion, and enable the second portion to be arranged opposite to the positive winding middle section, where in a winding axial direction of the winding type electrode assembly, a negative active material layer of the negative electrode plate exceeds a positive active material layer of the positive electrode plate, a maximum width of a negative active material layer of the first portion is $H1$, a minimum width of a positive active material layer of the first positive winding end portion is $L1$, a maximum width of a negative active material layer of the second portion is $H2$, a minimum width of a positive active material layer of the positive winding middle section is $L2$, and $H1-L1 > H2-L2$.

In the above technical solution, a width difference between the maximum width of the negative active material layer of the first portion of the provided negative electrode plate and the minimum width of the positive active material layer of the first positive winding end portion of the provided positive electrode plate is larger than a width difference between the maximum width of the negative active material layer of the second portion of the negative electrode plate and the minimum width of the positive active material layer of the positive winding middle section of the positive electrode plate, so that the risk of lithium plating caused by the reason that a size of a part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement due to relative deviation between the first portion and the first positive winding end portion caused by a winding technology, a winding device, etc. may be reduced.

In a sixth aspect, the embodiments of the present application provide a device for manufacturing a winding type electrode assembly, which includes: a first providing apparatus, a second providing apparatus and an assembling apparatus, where the first providing apparatus is configured to provide a positive electrode plate, the positive electrode

plate including a first positive winding end portion and a positive winding middle section connected to each other; the second providing apparatus is configured to provide a negative electrode plate, the negative electrode plate including a first portion and a second portion connected to each other; and the assembling apparatus is configured to wind the positive electrode plate and the negative electrode plate, so as to enable the first portion to be arranged opposite to the first positive winding end portion, and enable the second portion to be arranged opposite to the positive winding middle section, in a winding axial direction of the winding type electrode assembly, a negative active material layer of the negative electrode plate exceeds a positive active material layer of the positive electrode plate, a maximum width of a negative active material layer of the first portion is $H1$, a minimum width of a positive active material layer of the first positive winding end portion is $L1$, a maximum width of a negative active material layer of the second portion is $H2$, a minimum width of a positive active material layer of the positive winding middle section is $L2$, and $H1-L1 > H2-L2$.

In the above technical solution, in a process of forming the winding type electrode assembly through winding, the positive electrode plate and the negative electrode plate provided by the first providing apparatus and the second providing apparatus may reduce the risk of lithium plating caused by the reason that a size of a part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet a design requirement.

BRIEF DESCRIPTION OF DRAWINGS

To describe the technical solutions in the embodiments of the present application more clearly, the following briefly describes the accompanying drawings required in the embodiments of the present application. Apparently, the accompanying drawings in the following descriptions show merely some embodiments of the present disclosure, and a person of ordinary skill in the art can still derive other accompanying drawings from these accompanying drawings without creative efforts.

FIG. 1 is a structural schematic diagram of a vehicle provided by some embodiments of the present application;

FIG. 2 is an exploded view of a battery provided by some embodiments of the present application;

FIG. 3 is an exploded view of a battery cell provided by some embodiments of the present application;

FIG. 4 is a structural schematic diagram of a winding type electrode assembly provided by some embodiments of the present application;

FIG. 5 is a cutaway view of a P0-P0 direction in FIG. 4;

FIG. 6 is a structural schematic diagram of an electrode assembly, with a first positive winding end portion as a positive winding ending section, provided by some embodiments of the present application;

FIG. 7 is a structural schematic diagram of the electrode assembly, where a maximum width position of a negative active material layer of a first portion and a minimum width position of a positive active material layer of the first positive winding end portion are staggered, provided by some embodiments of the present application;

FIG. 8 is a structural schematic diagram of the electrode assembly, where the maximum width position of the negative active material layer of the first portion and the minimum width position of the positive active material layer of

the first positive winding end portion correspond to each other, provided by some embodiments of the present application;

FIG. 9 is a structural schematic diagram of a negative electrode plate provided by some embodiments of the present application;

FIG. 10 is a structural schematic diagram of the negative electrode plate, where one end of a first portion exceeds a second portion, provided by some embodiments of the present application;

FIG. 11 is a schematic diagram of a negative electrode plate formed through die cutting in the prior art;

FIG. 12 is a structural schematic diagram of the negative electrode plate, where one end of the first portion exceeds the second portion, provided by some other embodiments of the present application;

FIG. 13 is a structural schematic diagram of the negative electrode plate, where the first portion is inconsistent in width, provided by some embodiments of the present application;

FIG. 14 is a structural schematic diagram of the negative electrode plate, where the first portion is inconsistent in width, provided by still some embodiments of the present application;

FIG. 15 is a schematic structural diagram of the negative electrode plate provided by still some embodiments of the present application;

FIG. 16 is a structural schematic diagram of the negative electrode plate provided by some other embodiments of the present application;

FIG. 17 is a structural schematic diagram of the negative electrode plate provided by some other embodiments of the present application;

FIG. 18 is a structural schematic diagram of the negative electrode plate, a connection surface of which is oblique, provided by some embodiments of the present application;

FIG. 19 is a schematic structural diagram of the negative electrode plate, a first side face and the connection surface of which are not coplanar, provided by some embodiments of the present application;

FIG. 20 is a structural schematic diagram of the negative electrode plate, where a negative active material layer of a negative tab and the negative active material layer of a negative body are connected, provided by some embodiments of the present application;

FIG. 21 is a structural schematic diagram of an electrode assembly provided by some embodiments of the present application;

FIG. 22 is a cutaway view of a P1-P1 direction in FIG. 19;

FIG. 23 is a structural schematic diagram of the electrode assembly provided by some other embodiments of the present application;

FIG. 24 is a cutaway view of a P2-P2 direction in FIG. 21 under some conditions;

FIG. 25 is a cutaway view of the P2-P2 direction in FIG. 21 under some other conditions;

FIG. 26 is a structural schematic diagram of the electrode assembly with a first extending portion provided by some embodiments of the present application;

FIG. 27 is a structural schematic diagram of the electrode assembly with the first extending portion provided by some other embodiments of the present application;

FIG. 28 is a structural schematic diagram of the electrode assembly provided by still other embodiments of the present application;

FIG. 29 is a structural schematic diagram of the negative electrode plate with the first portion, the second portion and a third portion provided by some embodiments of the present application;

FIG. 30 is a cutaway view of a P3-P3 direction in FIG. 28;

FIG. 31 is a structural schematic diagram of the winding type electrode assembly provided by some other embodiments of the present application;

FIG. 32 is a cutaway view of a P4-P4 direction in FIG. 29;

FIG. 33 is a structural schematic diagram of the electrode assembly provided by some other embodiments of the present application;

FIG. 34 is a cutaway view of a P5-P5 direction in FIG. 31 under some conditions;

FIG. 35 is a cutaway view of the P5-P5 direction in FIG. 31 under some other conditions;

FIG. 36 is a structural schematic diagram of the electrode assembly with a second extending portion provided by some embodiments of the present application;

DESCRIPTION OF EMBODIMENTS

To make the objectives, technical solutions, and advantages of the embodiments of the present application clearer, the following will clearly describes the technical solutions in the embodiments of the present application with reference to the accompanying drawings in the embodiments of the present application the described embodiments are some rather than all of the embodiments of the present application. Based on the embodiments of the present application, all other embodiments obtained by those of ordinary skill in the art without making creative efforts fall within the scope of protection of the present application.

Unless otherwise defined, all technical and scientific terms used in the present application have the same meanings as those commonly understood by those who belong to the technical field of the present application. In the present application, the terms used in the specification of the present application are merely for the purpose of describing specific embodiments, and are not intended to limit the present application. The terms “including” and “having” and any variations thereof in the specification and claims of the present application and the above accompanying drawings are intended to cover non-exclusive inclusion. The terms “first”, “second”, etc. in the specification and claims of the present application or the above accompanying drawings are used to distinguish different objects, but not to describe a specific order or primary and secondary relationship.

Reference to an “embodiment” in the present application means that a specific feature, structure or characteristic described in conjunction with an embodiment may be included in at least one embodiment of the present application. The appearance of this phrase in various places in the specification does not necessarily mean the same embodiment, nor is it an independent or alternative embodiment mutually exclusive with other embodiments.

In the description of the present application, it should be noted that, unless otherwise explicitly specified and defined, the terms “mounting”, “connecting”, “connection” and “attachment” should be understood in a broad sense, for example, they may be a fixed connection, a detachable connection, or an integrated connection; and may be a direct connection, or an indirect connection via an intermediate medium, or communication inside two elements. For those of ordinary skill in the art, the specific meanings of the above terms in the present application could be understood according to specific circumstances.

In the embodiments of the present application, the same reference numerals refer to same parts, and for the sake of brevity, detailed descriptions of the same parts are omitted in different embodiments. It should be understood that a thickness, a length, a width and other dimensions of various parts and an overall thickness, length, width and other dimensions of an integrated device shown in the accompanying drawings in the embodiments of the present applica-

tion are merely exemplary, and should not constitute any limitation on the present application.

The term “a plurality of” in the present application means two or more.

In the present application, battery cells may include a lithium ion secondary battery, a lithium ion primary battery, a lithium-sulfur battery, a sodium lithium-ion battery, a sodium ion battery, a magnesium ion battery, etc., which is not limited by the embodiments of the present application. The battery cell may be cylindrical, flat, cuboid or in other shapes, which is not limited by the embodiments of the present application. Generally, the battery cells are divided into three types according to a packaging mode: cylindrical battery cells, square battery cells and pouch battery cells, which is not limited by the embodiments of the present application.

A battery mentioned in the embodiment of the present application refers to a single physical module which includes one or a plurality of battery cells and therefore provides a higher voltage and capacity. For example, the battery mentioned in the present application may include a battery module, a battery pack, etc. Generally, the battery includes a box body for packaging one or a plurality of battery cells. The box body may prevent other foreign matter from affecting charging or discharging of the battery cell.

The battery cell includes an electrode assembly and an electrolyte solution, where the electrode assembly consists of a positive electrode plate, a negative electrode plate and a separator film. The battery cell works mainly depending on movement of metal ions between the positive electrode plate and the negative electrode plate. The positive electrode plate includes a positive current collector and a positive active material layer, the positive active material layer coating a surface of the positive current collector. A lithium ion battery is taken as an example, the positive current collector may be made from aluminum, and a positive active material may be lithium cobalt oxide, lithium iron phosphate, ternary lithium, lithium manganate, etc. The negative electrode plate includes a negative current collector and a negative active material layer, the negative active material layer coating a surface of the negative current collector. The negative current collector may be made from copper, and a negative active material may be carbon, silicon, etc. In order to guarantee that fusing does not occur during large current flow, there are a plurality of positive tabs, the plurality of positive tabs are stacked together, there are a plurality of negative tabs, and the plurality of negative tabs are stacked together. The separator film may be made from PP (polypropylene), PE (polyethylene), etc. In addition, in the present application, the electrode assembly is of a winding type structure.

For development of a battery technology, various design factors should be considered at the same time, such as energy density, cycle life, discharge capacity, charge-discharge rates and other performance parameters. In addition, safety of the battery needs to be further considered. Lithium plating is one of the main factors affecting electrical performance and safety performance of the battery. Once the lithium plating occurs, it may reduce the electrical performance of the battery, and may be likely to form dendrites with accumulation of the lithium plating, which may puncture the separator film and cause short circuit in the battery, resulting in potential safety hazards. There are many reasons for the lithium plating.

The applicant finds that there is a problem of the lithium plating at a winding start end and a winding tail end of the electrode assembly. After analysis, it is found that the reason

13

that a size of a part, exceeding the positive active material layer of the positive electrode plate in a winding axial direction, of the negative active material layer of the negative electrode plate does not meet a design requirement is one of the main reasons for the lithium plating. Further studies indicate that several reasons why the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement are as follows:

As for a head of the electrode assembly (the winding start end of the electrode assembly), due to an inaccurate feeding position, feeding and drawing out a wound winding type electrode assembly from a winding needle, a structural error of a winding device, or no binding of a head of the positive electrode plate and a head of the negative electrode plate, it is likely to cause relative deviation between the head of the positive electrode plate and the head of the negative electrode plate, resulting in that a size of a part, exceeding the positive electrode plate in the winding axial direction, of the negative electrode plate does not meet the design requirement.

As for a tail of the electrode assembly (the winding tail end of the electrode assembly), the negative electrode plate may be cut off when winding is about to finish, so there is no tension at the tail of the cut negative electrode plate, and a tail of the negative electrode plate is likely to deviate from a tail of the positive electrode plate when the winding is finished. In addition, after the winding is completed, the electrode assembly needs to transfer hot pressing, which is likely to cause relative deviation between the tail of the positive electrode plate and the tail of the negative electrode plate in a transfer process, thus causing the size of the part, exceeding the positive electrode plate in the winding axial direction, of the negative electrode plate to be incapable of meeting the design requirement.

In view of this, the embodiments of the present application provide a technical solution, and a maximum width difference between a negative active material layer of the negative electrode plate at the head or tail and a positive active material layer of the positive electrode plate is larger than a maximum width difference between a negative active material layer of a middle section and the positive active material layer of the positive electrode plate, so that the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate in the winding axial direction, of the negative active material layer of the negative electrode plate does not meet the design requirement is reduced.

The technical solution described in the embodiment of the present application is applicable to a battery and a power consumption device using the battery.

The power consumption device may be a vehicle, a mobile phone, a portable apparatus, a notebook computer, a ship, a spacecraft, an electric toy, an electric tool, etc. The vehicles may be a fuel vehicle, a gas vehicle or a new energy vehicle, and the new energy vehicle may be a pure electric vehicle, a hybrid electric vehicle, an extended-range vehicle, etc. The spacecraft includes an aircraft, a rocket, a space shuttle, a spaceship, etc. The electric toy includes fixed or mobile electric toys, such as a game machine, an electric car toy, an electric boat toy and an electric airplane toy. The electric tool includes a metal cutting electric tool, a grinding electric tool, an assembling electric tool and a railway electric tool, such as an electric drill, an electric grinder, an electric wrench, an electric screwdriver, an electric hammer, an impact electric drill, a concrete vibrator and an electric

14

planer. The embodiment of the present application does not make special restrictions on the above power consumption device.

In the following embodiments, a vehicle **1000** is taken as an example of the power consumption device for the convenience of description.

With reference to FIG. 1, FIG. 1 is a structural schematic diagram of the vehicle **1000** provided by some embodiments of the present application. A battery **100** is arranged inside the vehicle **1000**, and the battery **100** may be arranged at a bottom, a head or a tail of the vehicle **1000**. The battery **100** may be configured to supply power to the vehicle **1000**, for example, the battery **100** may be configured to an operating power source of the vehicle **1000**. The vehicle **1000** may further include a controller **200** and a motor **300**, where the controller **200** is configured to control the battery **100** to supply power to the motor **300**, for example, for working power requirements during starting, navigating and driving the vehicle **1000**.

In some embodiments of the present application, the battery **100** may not only be used as an operating power source for the vehicle **1000**, but serve as a driving power source for the vehicle **1000**, replacing or partially replacing fuel or natural gas to provide driving power for the vehicle **1000**.

As shown in FIG. 2, the battery **100** includes a box body **10** and a battery cell **20**, where the battery cell **20** is accommodated in the box body **10**, the box body **10** provides an accommodating space for the battery cell **20**, the box body **10** includes a first box body portion **11** and a second box body portion **12**, and the first box body portion **11** and the second box body portion **12** are configured to jointly define the accommodating space for accommodating the battery cell **20**. In the battery **100**, there may be one or more battery cells **20**. If there are a plurality of battery cells **20**, the plurality of battery cells **20** may be connected to one another in series, in parallel or in hybrid, the hybrid connection means that the plurality of battery cells **20** are connected in both series and parallel. The plurality of battery cells **20** may be directly connected in series, in parallel or in hybrid, and then a whole formed by the plurality of battery cells **20** can be accommodated in the box body **10**. Of course, the plurality of battery cells **20** may be connected in series, in parallel or in hybrid to form a battery module firstly, and then a plurality of battery modules are connected in series, in parallel or in hybrid to form a whole to be accommodated in the box body **10**. The battery cell **20** may be cylindrical, flat, or in other shapes.

In some embodiments, the battery **100** may further include a bus component (not shown in the figure), and a plurality of battery cells **20** may be electrically connected to one another by means of the bus component, so as to realize series connection, parallel connection or parallel-series connection of the plurality of the battery cells **20**.

With reference to FIG. 3, FIG. 3 shows an exploded view of the battery cell **20** provided by some embodiments of the present application. The battery cell **20** includes a housing **21**, an end cover assembly **22** and an electrode assembly **23**, where the housing **21** is provided with an opening, the electrode assembly **23** is accommodated in the housing **21**, and the end cover assembly **22** is used to cover the opening. The housing **21** may be in various shapes, such as a cylinder and a flat shape. A shape of the housing **21** may be determined according to a specific shape of the electrode assembly **23**. For example, if the electrode assembly **23** is of a cylinder structure, the housing **21** may be selected to be of a cylinder structure. If the electrode assembly **23** is of a flat

15

structure, the housing 21 may be selected to be of a cuboid structure. The housing 21 may be made from various materials, such as copper, iron, aluminum, stainless steel and aluminum alloy, which is not specifically limited in the embodiment of the present application.

There may be one or more electrode assemblies 23 of the battery cell 20. FIG. 3 shows the battery cell 20 with the rectangular housing 21 and the two flat electrode assemblies 23 as an example. In FIG. 3, the two electrode assemblies 23 are arranged side by side.

With reference to FIGS. 4 and 5, FIG. 4 is a structural schematic diagram of a winding type electrode assembly 23 provided by some embodiments of the present application, and FIG. 5 is a cutaway view of a P0-P0 direction in FIG. 4. The electrode assembly 23 includes the positive electrode plate 231, the negative electrode plate 232 and the separator film 233, and the positive electrode plate 231, the negative electrode plate 232 and the separator film 233 are arranged in a stacking mode and wound in a winding direction A to form the electrode assembly 23. The separator film 233 is configured to separate the positive electrode plate 231 from the negative electrode plate 232, thus avoiding the short circuit in the battery 100 or the battery cell 20.

The positive electrode plate 231 includes the positive tab 2311 and a positive body 2312, the positive body 2312 of the positive tab 231 includes a first positive winding end portion 23121 and a positive winding middle section 23122 connected to each other, and the positive tab 2311 protrudes out of the positive body 2312 in the winding axial direction B; and the negative electrode plate 232 includes a negative body 2322 and the negative tab 2321, the negative body 2322 of the negative electrode plate 232 includes a first portion 23221 and a second portion 23222 connected to each other, and the negative tab 2321 protrudes out of the negative body 2322 in the winding axial direction B. In a thickness direction of the positive electrode plate 231, the positive tab 2311 may protrude out of the positive body 2312 and may not protrude out of the positive body 2312, for example, if the positive tab 2311 is welded to one end of the positive body 2312 in the winding axial direction B, the positive tab 2311 may protrude out of the positive body 2312 in the thickness direction; and if the positive tab 2311 is formed by die cutting the positive current collector, the positive tab 2311 may not protrude out of the positive body 2312. In a thickness direction of the negative electrode plate 232, the negative tab 2321 may protrude out of the negative body 2322 and may not protrude out of the negative body 2322, for example, if the negative tab 2321 is welded to one end of the negative body 2322 in the winding axial direction B, the negative tab 2321 may protrude out of the negative body 2322 in the thickness direction; and if the negative tab 2321 is formed by die cutting the negative current collector, the negative tab 2321 may not protrude out of the negative body 2322. When the electrode assembly is in a winding state, the thickness direction of the positive electrode plate 231 is perpendicular to the winding axial direction B of the electrode assembly 23, and the thickness direction of the negative electrode plate 232 is perpendicular to the winding axial direction B of the electrode assembly 23.

The first portion 23221 is arranged opposite to the first positive winding end portion 23121, and the second portion 23222 is arranged opposite to the positive winding middle section 23122; and in the winding axial direction B of the winding type electrode assembly 23, the negative active material layer of the negative electrode plate 232 exceeds the positive active material layer of the positive electrode plate 231, a maximum width of a negative active material

16

layer 23221a of the first portion is H1, a minimum width of a positive active material layer 23121a of the first positive winding end portion is L1, a maximum width of a negative active material layer 23222a of the second portion is H2, a minimum width of a positive active material layer 23122a of the positive winding middle section is L2, and $H1-L1 > H2-L2$.

A width difference between the maximum width of the negative active material layer 23221a of the first portion and the minimum width of the positive active material layer 23121a of the first positive winding end portion is set to be larger than a width difference between the maximum width of the negative active material layer 23222a of the second portion and the minimum width of the positive active material layer 23122a of the positive winding middle section, that is, a maximum width difference between the positive active material layer 23121a of the first positive winding end portion and the negative active material layer 23221a of the first portion is larger than a maximum width difference between the negative active material layer 23222a of the second portion and the positive active material layer 23122a of the positive winding middle section, so that the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate 231 in the winding axial direction B, of the negative active material layer of the negative electrode plate 232 does not meet the design requirement is reduced.

It should be noted that a width of a positive active material of the positive electrode plate 231 and a width of a negative active material of the negative electrode plate 232 both refers to sizes of the winding type electrode assembly 23 in the winding axial direction B. The maximum width of the negative active material layer 23221a of the first portion refers to a maximum size of the negative active material layer 23221a of the first portion in the winding axial direction B; the minimum width of the positive active material layer 23121a of the first positive winding end portion refers to a minimum size of the positive active material layer 23121a of the first positive winding end portion in the winding axial direction B; the maximum width of the negative active material layer 23222a of the second portion refers to a maximum size of the negative active material layer 23222a of the second portion in the winding axial direction B; and the minimum width of the positive active material layer 23122a of the positive winding middle section refers to a minimum size of the positive active material layer 23122a of the positive winding middle section in the winding axial direction B.

The maximum width difference refers to a difference between the maximum width and the minimum width, and the maximum width difference between the positive active material layer 23121a of the first positive winding end portion and the negative active material layer 23221a of the first portion refers to $H1-L1$; and the maximum width difference between the negative active material layer 23222a of the second portion and the positive active material layer 23122a of the positive winding middle section refers to $H2-L2$.

In some embodiments, with reference to FIGS. 4 and 5, the first positive winding end portion 23121 is a positive winding starting section, the first positive winding end portion 23121 is the positive body 2312 wound for a certain distance from a start end 23121b of the positive winding starting section in the winding direction A of the winding type electrode assembly 23, and the positive winding middle section 23122 is the positive body 2312 connected to the tail

17

end of the first positive winding end portion **23121** (a tail end **23121c** of the positive winding starting section) and wound in the winding direction A of the winding type electrode assembly **23** for a certain distance.

Apart with a large line width shown in the present application is a part with an increased width of the negative active material layer of the negative electrode plate **232**, which does not mean that a thickness of the part with the large line width of the negative electrode plate **232** is larger than that of a part with a small line width of the negative electrode plate **232**, and when the electrode assembly is in the winding state, the thickness direction of the negative electrode plate **232** is perpendicular to the winding axial direction B of the electrode assembly **23**.

The first portion **23221** is arranged opposite to the first positive winding end portion **23121**, that is, the first portion **23221** is arranged opposite to the positive winding starting section, which is further described as that a start end **23221d** of the first portion corresponds to the start end **23121b** of the positive winding starting section, and a tail end **23221e** of the first portion corresponds to the tail end **23121c** of the positive winding starting section.

When the first positive winding end portion **23121** is the positive winding starting section, a positive active material layer of the positive winding starting section and the negative active material layer **23221a** of the first portion meet a condition that $H1-L1>H2-L2$, so that a possibility that due to the inaccurate feeding position, feeding and drawing out the wound winding type electrode assembly from the winding needle, the structural error of the winding device, or no binding of the positive winding starting section and the first portion **23221**, thus causing relative deviation between the positive winding starting section and the first portion **23221**, resulting in that the size of the part, exceeding the positive electrode plate **231** in the winding axial direction B, of the negative electrode plate **232** does not meet the design requirement may be reduced.

In some embodiments, as shown in FIG. 6, the first positive winding end portion **23121** is a positive winding ending section, the first positive winding end portion **23121** is the positive body **2312** wound for a certain distance from a tail end **23121d** of the positive winding ending section in a direction opposite to the winding direction A of the winding type electrode assembly **23**, and the positive winding middle section **23122** is the positive body **2312** connected to a start end of the first positive winding end portion **23121** (a start end **23121e** of the positive winding ending section) and wound in the direction opposite to the winding direction A of the winding type electrode assembly **23** for a certain distance.

The first portion **23221** is arranged opposite to the first positive winding end portion **23121**, that is, the first portion **23221** is arranged opposite to the positive winding ending section, which is further described as that a tail end **23221e** of the first portion corresponds to the tail end **23121d** of the positive winding ending section, and the start end **23221d** of the first portion corresponds to the start end **23121e** of the positive winding ending section. A positive active material layer of the positive winding ending section and the negative active material layer **23221a** of the first portion meet the condition that $H1-L1>H2-L2$, so that a possibility that when the winding is about to finish, there is no tension at the first portion **23221** after the negative electrode plate **232** is cut, and after the winding is completed, the electrode assembly **23** needs to transfer hot pressing, which is likely to cause relative deviation between the first portion **23221** and the positive winding ending section in the transfer

18

process, thus causing the size of the part, exceeding the positive electrode plate **231** in the winding axial direction B, of the negative electrode plate **232** to be incapable of meeting the design requirement may be reduced.

In the winding direction A, each position on the positive active material layer **23121a** of the first positive winding end portion has a corresponding position of the negative active material layer **23221a** of the first portion. In some embodiments, a maximum width position of the negative active material layer **23221a** of the first portion and a minimum width position of the positive active material layer **23121a** of the first positive winding end portion are staggered. For example, in FIG. 7, M1 is the maximum width position of the negative active material layer **23221a** of the first portion, N1 is the minimum width position of the positive active material layer **23121a** of the first positive winding end portion, and M1 and N1 are staggered in the winding direction A. In FIG. 7, a dotted line except a dotted line representing the separator film **233** is only used to clarify a relative positional relation between M1 and N1.

In some embodiments, the maximum width position of the negative active material layer **23221a** of the first portion corresponds to a minimum width position of the first positive winding end portion **23121**. For example, in FIG. 8, M2 is the maximum width position of the negative active material layer **23221a** of the first portion, N2 is the minimum width position of the positive active material layer **23121a** of the first positive winding end portion, and M2 corresponds to N2. In FIG. 8, a dotted line except the dotted line representing the separator film **233** is only used to clarify a relative positional relation between M2 and N2.

In order to realize the purpose that the maximum width difference between the positive active material layer **23121a** of the first positive winding end portion and the negative active material layer **23221a** of the first portion is larger than the maximum width difference between the negative active material layer **23222a** of the second portion and the positive active material layer **23122a** of the positive winding middle section, improvement may be made to the negative electrode plate **232** or the positive electrode plate **231** or the positive electrode plate **231** and the negative electrode plate **232**.

In some embodiments, a structure of the negative electrode plate **232** is improved so as to enable the maximum width difference between the positive active material layer **23121a** of the first positive winding end portion and the negative active material layer **23221a** of the first portion to be larger than the maximum width difference between the negative active material layer **23222a** of the second portion and the positive active material layer **23122a** of the positive winding middle section.

In some embodiments, with reference to FIG. 9, FIG. 9 is a structural schematic diagram of the negative electrode plate **232** provided by some embodiments of the present application. In the winding axial direction B (consistent with a shown width direction C), the negative active material layer **23221a** of the first portion and the negative active material layer **23222a** of the second portion have a width difference, that is, $H1>H2$, which means that a width of the negative active material layer **23221a** of the first portion is increased compared with the negative active material layer **23222a** of the second portion, so that on the premise of guaranteeing the energy density, the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate **231** in the winding axial direction B, of the negative active material layer of the negative electrode plate **232** does not meet the design requirement may be reduced.

In some embodiments, a minimum width of the negative active material layer **23221a** of the first portion is $H3 > H2$. The maximum width of the negative active material layer **23221a** of the first portion is larger than the maximum width of the negative active material layer **23222a** of the second portion, and the minimum width of the negative active material layer **23221a** of the first portion is not less than the maximum width of the negative active material layer **23222a** of the second portion, so that a possibility of the lithium plating caused by the reason that a size of a part, exceeding the positive active material layer **23121a** of the first positive winding end portion in the winding axial direction B, of the negative active material layer **23221a** of the first portion does not meet the design requirement due to relative deviation between the first positive winding end portion **23121** and the first portion **23221** may be reduced.

When a width of the first portion **23221** is too large, it is possible that the width exceeds a width of the separator film **233** and the first portion further interferes with an end cover assembly **22** (as shown in FIG. 3), increasing the short circuit risk; and if the width of the first portion **23221** is too small, the first portion is likely affected by a tolerance of a winding device and cannot cover the first positive winding end portion **23121**. In some embodiments, $0.3 \text{ mm} \leq H1 - H2 \leq 3 \text{ mm}$ may guarantee use safety of the winding type electrode assembly **23**, may enable the first portion **23221** of the negative electrode plate **232** to cover the first positive winding end portion **23121**, and reduces the possibility that the size of the part, exceeding the positive active material layer of the positive electrode plate **231** in the winding axial direction B, of the negative active material layer of the negative electrode plate **232** does not meet the design requirement. In some embodiments, $0.3 \text{ mm} \leq H1 - H2 \leq 1.5 \text{ mm}$.

In some embodiments, with further reference to FIG. 9, the negative active material layer **23221a** of the first portion is of an equal-width structure, that is, the negative active material layer **23221a** of the first portion is consistent in width, and $H1 = H3$.

In some embodiments, as shown in FIG. 9, in the winding axial direction B (consistent with the shown width direction C), two ends of the negative active material layer **23221a** of the first portion exceed two ends of the negative active material layer **23222a** of the second portion correspondingly. A dotted line in FIG. 9 is only used to distinguish the first portion **23221** from the second portion **23222**, and does not affect the structure of the negative electrode plate **232**.

In some embodiments, as shown in FIG. 10, in the winding axial direction B (consistent with the shown width direction C), one end of the negative active material layer **23221a** of the first portion exceeds a corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative active material layer **23221a** of the first portion is flush with the other end of the negative active material layer **23222a** of the second portion. A dotted line in FIG. 10 is only used to distinguish the first portion **23221** from the second portion **23222**, and does not affect the structure of the negative electrode plate **232**.

The fact that the end of the negative active material layer **23221a** of the first portion exceeds the corresponding end of the negative active material layer **23222a** of the second portion means that in the winding axial direction, the end of the negative active material layer **23221a** of the first portion exceeds one end of the negative active material layer **23222a**

of the second portion closest to the negative active material layer **23221a** of the first portion in the winding axial direction B.

In some embodiments, with further reference to FIG. 10, in the winding axial direction B (consistent with the shown width direction C), the negative tab **2321** is located at one end of the negative electrode plate **232**, one end of the negative active material layer **23221a** of the first portion close to the negative tab **2321** exceeds a corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative active material layer **23221a** of the first portion is flush with the other end of the negative active material layer **23222a** of the second portion, which means that the other end of the negative active material layer **23221a** of the first portion and the other end of the negative active material layer **23222a** of the second portion are coplanar. In the winding axial direction B, one end of the negative active material layer **23221a** of the first portion close to the negative tab **2321** completely exceeds the corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative active material layer **23221a** of the first portion is flush with the other end of the negative active material layer **23222a** of the second portion.

As shown in FIG. 11, the negative electrode plate **232** is generally formed by applying a negative active material layer consistent in width to the negative current collector and then forming the negative tab **2321** on two sides of the negative current collector in the width direction C through die cutting. The two negative electrode plates **232** with the negative tabs **2321** on single sides are formed on a middle position in the width direction C through cutting, that is, the two negative electrode plates **232** are formed in a dotted line direction in FIG. 11 through die cutting. One end of the negative active material layer **23221a** of the first portion close to the negative tab **2321** exceeds the corresponding end of the negative active material layer **23222a** of the second portion, so that in a process of forming the negative tab **2321** through the die cutting, the negative electrode plate **232** with a width difference between the negative active material layer **23221a** of the first portion and the negative active material layer **23222a** of the second portion may be formed, that is, the negative electrode plate with the width difference between the negative active material layer **23221a** of the first portion and the negative active material layer **23222a** of the second portion may be formed by using an original forming process of the negative electrode plate **232**.

It should be noted that after the electrode assembly is formed through winding, the width direction C of the negative current collector is consistent with the winding axial direction B of the electrode assembly.

In some embodiments, as shown in FIG. 12, in the winding axial direction B (consistent with the shown width direction C), it may also be one end of the negative active material layer **23221a** of the first portion away from the negative tab **2321** that at least partially exceeds a corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative active material layer **23221a** of the first portion is flush with the other end of the negative active material layer **23222a** of the second portion. A dotted line in FIG. 12 is only used to distinguish the first portion **23221** from the second portion **23222**, and does not affect the structure of the negative electrode plate **232**.

In some embodiments, the negative active material layer **23221a** of the first portion is of a variable-width structure, that is, the negative active material layer **23221a** of the first

21

portion is inconsistent in width. The negative active material layer **23221a** of the first portion which is of the variable-width structure has various structural forms.

With reference to FIG. 13, the width of the negative active material layer **23221a** of the first portion gradually increases in a direction away from the second portion **23222**, and a width of any position of the negative active material layer **23221a** of the first portion is larger than the maximum width of the negative active material layer **23222a** of the second portion. A dotted line in FIG. 13 is only used to distinguish the first portion **23221** from the second portion **23222**, and does not affect the structure of the negative electrode plate **232**.

As shown in FIG. 14, a width of a part of the negative active material layer **23221a** of the first portion is smaller than a width of the other part of the negative active material layer **23221a** of the first portion, and in FIG. 14, widths of negative active material layers on two sides of the negative tab **2321** protruding out of the first portion **23221** are larger than a width of a negative active material layer at a connection position between the first portion **23221** and the negative tab **2321**. When $H3=H2$, one end of the negative active material layer **23221a** of the first portion close to the negative tab **2321** at least partially exceeds the negative active material layer **23222a** of the second portion, and when $H3>H2$, one end of the negative active material layer **23221a** of the first portion close to the negative tab **2321** completely exceeds the negative active material layer **23222a** of the second portion. A dotted line in FIG. 14 is only used to distinguish the first portion **23221** from the second portion **23222**, and does not affect the structure of the negative electrode plate **232**.

As long as the maximum width of the negative active material layer **23221a** of the first portion is larger than the maximum width of the negative active material layer **23222a** of the second portion and the minimum width of the negative active material layer **23221a** of the first portion is not less than the maximum width of the negative active material layer **23222a** of the second portion, the possibility of the lithium plating may be reduced. In this way, in the winding axial direction B, a width of the negative current collector **23221b** of the first portion and a width of the negative current collector **23222b** of the second portion may be consistent or not.

In some embodiments, with further reference to FIG. 15, in the winding axial direction B (consistent with the shown width direction C), the negative current collector **23221b** of the first portion and the negative current collector **23222b** of the second portion are consistent in width, one end of the negative active material layer **23221a** of the first portion close to the negative tab **2321** is flush with a corresponding end of the negative current collector **23221b** of the first portion, and the other end of the negative active material layer **23221a** of the first portion is flush with a corresponding end of the negative current collector **23221b** of the first portion; one end of the negative current collector **23222b** of the second portion close to the negative tab **2321** exceeds a corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative current collector **23222b** of the second portion is flush with a corresponding end of the negative active material layer **23222a** of the second portion; and one end of the negative active material layer **23221a** of the first portion close to the negative tab **2321** exceeds a corresponding end of the negative active material layer **23222a** of the second portion.

22

In some embodiments, as shown in FIG. 16, in the winding axial direction B (consistent with the shown width direction C), one end of the negative current collector **23221b** of the first portion away from the negative tab **2321** exceeds a corresponding end of the negative active material layer **23221a** of the first portion, and the other end of the negative current collector **23221b** of the first portion is flush with a corresponding end of the negative active material layer **23221a** of the first portion; one end of the negative current collector **23222b** away from the negative tab **2321** of the second portion exceeds a corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative current collector **23222b** of the second portion is flush with the corresponding end of the negative active material layer **23222a** of the second portion; and one end of the negative current collector **23221b** of the first portion away from the negative tab **2321** is flush with one end of the negative current collector **23222b** of the second portion away from the negative tab **2321**; and one end of the negative active material layer **23221a** of the first portion away from the negative tab **2321** is flush with a corresponding end of the negative active material layer **23222a** of the second portion, and one end of the negative active material layer **23221a** of the first portion close to the negative tab **2321** exceeds the corresponding end of the negative active material layer **23222a** of the second portion.

In some embodiments, as shown in FIG. 17, in the winding axial direction B (consistent with the shown width direction C), one end of the first portion **23221** close to the negative tab **2321** exceeds a corresponding end of the second portion **23222**, and the other end of the first portion **23221** is flush with the other end of the second portion **23222**. It may be understood that one end of the negative current collector **23221b** of the first portion close to the negative tab **2321** exceeds a corresponding end of the negative current collector **23222b** of the second portion, and the other end of the negative current collector **23221b** of the first portion is flush with the other end of the negative current collector **23222b** of the second portion; one end of the negative active material layer **23221a** of the first portion close to the negative tab **2321** exceeds the corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative active material layer **23221a** of the first portion is flush with the other end of the negative active material layer **23222a** of the second portion; one end of the negative current collector **23221b** of the first portion close to the negative tab **2321** is flush with one end of the negative active material layer **23221a** of the first portion close to the negative tab **2321**, and the other end of the negative current collector **23221b** of the first portion is flush with the other end of the negative active material layer **23221a** of the first portion; and one end of the negative current collector **23222b** of the second portion close to the negative tab **2321** is flush with one end of the negative active material layer **23222a** of the second portion close to the negative tab **2321**, and the other end of the negative current collector **23222b** of the second portion is flush with the other end of the negative active material layer **23222a** of the second portion. The negative electrode plate **232** not only facilitates coating of the negative active material layer, but also may form the negative electrode plate **232** with a width difference between the first portion **23221** and the second portion **23222** in the process of forming the negative tab **2321** through the die cutting, that is, the negative electrode plate with the width difference between the first portion **23221** and the second portion

23

23222 may be formed by using the original forming process of the negative electrode plate **232**.

In some embodiments, with further reference to FIG. 17, in the winding direction A, the first portion **23221** is provided with a connection surface **23221c** connected to the second portion **23222**; and negative tabs **2321** are multiple in quantity, one negative tab **2321** of the multiple negative tabs **2321** protrudes out of the first portion **23221** in the winding axial direction B and is provided with a first side face **2321a** close to the second portion **23222**, and the first side face **2321a** and the connection surface **23221c** are coplanar. The connection surface **23221c** connecting the first portion **23221** and the second portion **23222** is coplanar with one side face of the negative tab **2321**, so that a situation that the connection surface **23221c** warps due to no binding and then punctures the separator film **233** during and after winding may be avoided.

In some embodiments, with further reference to FIG. 17, in the winding axial direction B (consistent with the shown width direction C), an extending direction of the first side face **2321a** is consistent with the winding axial direction B, and the connection surface **23221c** is a flat face parallel to the first side face **2321a**, that is, an extending direction of the connection surface **23221c** is consistent with the winding axial direction B.

In some embodiments, as shown in FIG. 18, the first side face **2321a** is an inclined face which gradually inclines to the second portion **23222** from top to bottom in the figure, the connection surface **23221c** is also an inclined face, and in the winding axial direction B, the connection surface **23221c** gradually inclines to the second portion **23222** from one end close to the negative tab **2321**.

In some embodiments, as shown in FIG. 19, the connection surface **23221c** may also be located between the two adjacent negative tabs **2321** and not coplanar with a side face of any negative tab **2321**.

In some embodiments, there may be one negative tab **2321**, and the first side face **2321a** of the negative tab **2321** is coplanar or not coplanar with the connection surface **23221c**.

In some embodiments, as shown in FIG. 20, in the winding axial direction B (consistent with the shown width direction C), the negative tab **2321** protruding out of the first portion **23221** is provided with a negative active material layer, and the negative active material layer **2321b** on the negative tab protruding out of the first portion **23221** is connected to the negative active material layer **23221a** of the first portion. The negative active material layer on the negative tab **2321** may further cover the positive electrode plate **231**, which means that a width of a negative active material layer of part of the first portion **23221** is further increased, so that the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate **231** in the winding axial direction B, of the negative active material layer of the negative electrode plate **232** does not meet the design requirement may be further reduced.

In some embodiments, with reference to FIG. 21, the winding type electrode assembly **23** includes a straight area I and two bent areas II, and the two bent areas II are connected to two ends of the straight area I respectively. The first portion **23221** passes through the straight area I at least two times. In fact, after the first portion **23221** passes through the straight area I two times, a winding length is close to a length of a circle, when the next circle of winding is started, a certain binding effect is made on the start end **23121b** of the positive winding starting section and a start

24

end of the negative electrode plate **232**, and a possibility of relative deviation between the first positive winding end portion **23121** and the first portion **23221** is small, so the first portion **23221** passes through the straight area I at least two times, which may reduce the possibility of the lithium plating caused by the reason that the size of the part, exceeding the negative active material layer **23221a** of the first portion in the winding axial direction B, of the positive active material layer **23121a** of the first positive winding end portion does not meet the design requirement due to relative deviation between the first positive winding end portion **23121** and the first portion **23221** as much as possible.

An inner side and an outer side of the positive current collector of the positive electrode plate **231** are both coated with positive active material layers, widths of the positive active material layers on the inner side and the outer side of the positive current collector of the positive electrode plate **231** may be consistent or not, an inner side and an outer side of the negative current collector of the negative electrode plate **232** are both coated with negative active material layers, and widths of the negative active material layers on the inner side and the outer side of the negative current collector of the negative electrode plate **232** may be consistent or not.

In some embodiments, comparison between the width of the negative active material layer **23221a** of the first portion and a width of the positive active material layer **23121a** of the first positive winding end portion may be made by comparing only a width of a negative active material layer of the first portion **23221** facing the first positive winding end portion **23121** and a width of a positive active material layer of the first positive winding end portion **23121** facing the first portion **23221**, so that only the width of the negative active material layer of the first portion **23221** facing the first positive winding end portion **23121** may be increased so as to meet $H1-L1>H2-L2$.

It should be noted that the inner sides and the outer sides of the positive current collector of the positive electrode plate **231** and the negative current collector of the negative electrode plate **232** are defined with respect to a winding axis, one side of the positive current collector of the positive electrode plate **231** close to winding axis is the inner side of the positive current collector of the positive electrode plate **231**, one side of the positive electrode plate **231** away from the winding axis is the outer side of the positive current collector of the positive electrode plate **231**, one side of the negative current collector of the negative electrode plate **232** close to the winding axis is the inner side of the negative current collector of the negative electrode plate **232**, and one side of the negative current collector of the negative electrode plate **232** away from the winding axis is the outer side of the negative current collector of the negative electrode plate **232**.

In some embodiments, as shown in FIGS. 21 and 22, the first portion **23221** passes through the straight area I two times, the first positive winding end portion **23121** passes through the straight area I two times. The negative active material layers on the outer sides of the negative current collector **23221b** of the first portion in the two straight areas I face a positive active material on an inner side of a positive current collector **23121f** of the first positive winding end portion, so that only the negative active material layers on the outer sides of the negative current collector **23221b** of the first portion in the two straight areas I may be widened so as to meet $H1-L1>H2-L2$.

In some embodiments, as shown in FIGS. 23 and 24, the first portion **23221** passes through the straight area I three

25

times, which is divided into a straight area for first time, a straight area for second time and a straight area for third time according to a passing sequence (first→later). If the first positive winding end portion **23121** passes through the straight area I two times, a negative active material layer on an inner side of the negative current collector **23221b** of the first portion in the straight area for third time faces a positive active material layer on an outer side of a part of the positive current collector **23121f** of the first positive winding end portion in the straight area for first time, and negative active material layers on outer sides of parts of the negative current collector **23221b** of the first portion in the straight area for the first time and the straight area for second time face a positive active material layer on an inner side of the positive current collector **23121f** of the first positive winding end portion, so that in the winding axial direction B, only the negative active material layers on the outer sides of the negative current collector **23221b** of the first portion in the straight area for the first time and the straight area for second time and the negative active material layer on the inner side of the part of the negative current collector **23221b** of the first portion in the straight area for third time may be widened so as to meet $H1-L1>H2-L2$.

As shown in FIG. 25, if the first positive winding end portion **23121** passes through the straight area I three times, negative active material layers on the inner and outer sides of the part of the negative current collector **23221b** of the first portion in the straight area for third time face a positive active material layer on an outer side of a part of the positive current collector **23121f** of the first positive winding end portion in the straight area for first time and a positive active material layer on an inner side of a part of the positive current collector **23121f** of the first positive winding end portion in the straight area for third time respectively. The negative active material layers on the outer sides of the parts of the negative current collector **23221b** of the first portion in the straight area for the first time and the straight area for second time face positive active material layers on inner sides of the positive current collector **23121f** of the first positive winding end portion in the straight area for the first time and the straight area for second time, so that in the winding axial direction, only the negative active material layers on the outer sides of the parts of the negative current collector **23221b** of the first portion in the straight area for the first time and the straight area for second time and the negative active material layers on the inner and outer sides of the part of the negative current collector **23221b** of the first portion in the straight area for third time may be widened so as to meet $H1-L1>H2-L2$.

In some embodiments, the winding type electrode assembly **23** is the cylindrical electrode assembly **23**, and the first portion **23221** is wound at least one circle.

As shown in FIG. 26, in order to guarantee that the negative electrode plate **232** is capable of completely covering the positive electrode plate **231** in the winding direction A, the negative body **2322** further includes a first extending portion **23224**. In the winding direction A, the first extending portion **23224** is connected to one end of the first portion **23221** away from the second portion **23222**, and the first extending portion **23224** exceeds the start end (the start end **23121b** of the positive winding starting section) of the first positive winding end portion **23121** in the direction opposite to the winding direction A. A width of a negative active material layer of the first extending portion **23224** in the winding axial direction B may be increased or not increased compared with that of the negative active material layer **23222a** of the second portion. The negative active

26

material layer of the first extending portion **23224** is widened compared with the negative active material layer **23222a** of the second portion (with reference to FIG. 23). As shown in FIG. 26, the negative active material layer of the first extending portion **23224** is not widened compared with that of the negative active material layer **23222a** of the second portion.

In some embodiments, as shown in FIG. 27, the first extending portion **23224** is provided with the negative tab **2321** in a protruding mode, and in the winding direction A, negative active material layers of the first extending portion **23224** at two sides of the negative tab **2321** are widened compared with the negative active material layer **23222a** of the second portion. In some embodiments, in the winding direction A, in the negative active material layers of the first extending portion **23224** at the two sides of the negative tab **2321**, only one side of the negative active material layer is widened compared with the negative active material layer **23222a** of the second portion.

In some embodiments, as shown in FIG. 28, the positive body **2312** of the positive electrode plate **231** further includes a second positive winding end portion **23123**, and the first positive winding end portion **23121** and the second positive winding end portion **23123** are connected to two ends of the positive winding middle section **23122** respectively.

The negative body **2322** of the negative electrode plate **232** further includes a third portion **23223**, the first portion **23221** and the third portion **23223** are connected to two ends of the second portion **23222** respectively, and the third portion **23223** is arranged opposite to the second positive winding end portion **23123**; and a maximum width of a negative active material layer **23223a** of the third portion is $H4$, a minimum width of a positive active material layer **23123a** of the second positive winding end portion is $L3$, and $H4-L3>H2-L2$.

In some embodiments, the first positive winding end portion **23121** is the positive winding starting section, and the second positive winding end portion **23123** is the positive winding ending section. The first positive winding end portion **23121** is the positive body **2312** wound for a certain distance from the start end **23121b** of the positive winding starting section in the winding direction A of the winding type electrode assembly **23**, and the positive winding middle section **23122** is the positive body **2312** connected to the tail end of the first positive winding end portion **23121** (the tail end **23121c** of the positive winding starting section) and wound in the winding direction A of the winding type electrode assembly **23** for a certain distance. The second positive winding end portion **23123** is a positive body **2312** wound for a certain distance from a tail end **23121d** (a tail end of the second positive winding end portion **23123**) of the positive winding ending section in the direction opposite to the winding direction A of the winding type electrode assembly **23**, and the positive winding middle section **23122** is a positive body **2312** connected to a start end of the second positive winding end portion **23123** (the start end **23121e** of the positive winding ending section) and wound in the direction opposite to the winding direction A of the winding type electrode assembly **23** for a certain distance.

The third portion **23223** is arranged opposite to the second positive winding end portion **23123**, that is, the third portion **23223** is arranged opposite to the positive winding ending section, which is further described as that a start end **23223b** of the third portion corresponds to the start end of the second positive winding end portion **23123** (the start end **23121e** of the positive winding ending section), and a tail end **23223c**

of the third portion corresponds to the tail end of the second positive winding end portion **23123** (the tail end **23121d** of the positive winding ending section).

The maximum width difference between the positive active material layer **23121a** of the first positive winding end portion and the negative active material layer **23221a** of the first portion is larger than the maximum width difference between the negative active material layer **23222a** of the second portion and the positive active material layer **23122a** of the positive winding middle section, and the maximum width difference between the positive active material layer **23123a** of the second positive winding end portion and the negative active material layer **23223a** of the third portion is larger than a maximum width difference between the negative active material layer **23222a** of the second portion and the positive active material layer **23122a** of the positive winding middle section, so that the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate **231** in the winding axial direction, of the negative active material layer of the negative electrode plate **232** does not meet the design requirement due to relative deviation between the head of the positive electrode plate **231** and the head of the negative electrode plate **232** and between the tail of positive electrode plate **231** and the tail of the negative electrode plate **232** may be reduced.

In some embodiments, as shown in FIGS. **28** and **29**, $H4 > H2$. Due to the fact that the third portion **23223** is arranged opposite to the second positive winding end portion **23123** and the second portion **23222** is arranged opposite to the positive winding middle section **23122**, the maximum width of the negative active material layer **23223a** of the third portion is larger than the maximum width of the negative active material layer **23222a** of the second portion, which means that the negative active material layer **23223a** of the third portion is widened compared with the negative active material layer **23222a** of the second portion, so that on the premise of guaranteeing the energy density, the risk of the lithium plating caused by the reason that the size of the part, exceeding the positive active material layer of the positive electrode plate **231** in the winding axial direction B, of the negative active material layer of the negative electrode plate **232** does not meet the design requirement may be reduced.

In some embodiments, a minimum width of the negative active material layer **23223a** of the third portion is $H5$, and $H5 \geq H2$. The minimum width of the negative active material layer **23223a** of the third portion is not less than the maximum width of the negative active material layer **23222a** of the second portion, so that the risk of the lithium plating caused by the reason that a size of a part, exceeding the positive active material layer **23123a** of the second positive winding end portion in the winding axial direction B, of the negative active material layer **23223a** of the third portion does not meet the design requirement is reduced.

A structure of the third portion **23223** may refer to that of the first portion **23221**, a structural relation between the third portion **23223** and the second portion **23222** may refer to that between the first portion **23221** and the second portion **23222**, a structure of the second positive winding end portion **23123** may refer to that of the first positive winding end portion **23121**, and a relative relation between the second positive winding end portion **23123** and the third portion **23223** may refer to that between the first positive winding end portion **23121** and the first portion **23221**, which will not be described in detail herein.

With further reference to FIG. **29**, in the winding axial direction B (consistent with the shown width direction C), the negative tab **2321** is located at one end of the negative electrode plate **232**, one end of the negative active material layer **23223a** of the third portion close to the negative tab **2321** exceeds a corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative active material layer **23223a** of the third portion is flush with the other end of the negative active material layer **23222a** of the second portion. In the winding axial direction B, the end of the negative active material layer **23223a** of the third portion close to the negative tab **2321** completely exceeds the corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative active material layer **23223a** of the third portion is flush with the other end of the negative active material layer **23222a** of the second portion.

One end of the third portion **23223** close to the negative tab **2321** exceeds a corresponding end of the second portion **23222**, and the other end of the third portion **23223** is flush with the other end of the second portion **23222**. It may be understood that one end of a negative current collector **23223e** of the third portion close to the negative tab **2321** exceeds a corresponding end of the negative current collector **23222b** of the second portion, and the other end of the negative current collector **23223e** of the third portion is flush with the other end of the negative current collector **23222b** of the second portion; one end of the negative active material layer **23223a** of the third portion close to the negative tab **2321** exceeds the corresponding end of the negative active material layer **23222a** of the second portion, and the other end of the negative active material layer **23223a** of the third portion is flush with the other end of the negative active material layer **23222a** of the second portion; one end of the negative current collector **23223e** of the third portion close to the negative tab **2321** is flush with one end of the negative active material layer **23223a** of the third portion close to the negative tab **2321**, and the other end of the negative current collector **23223e** of the third portion is flush with the other end of the negative active material layer **23221a** of the first portion; and one end of the negative current collector **23222b** of the second portion close to the negative tab **2321** is flush with one end of the negative active material layer **23222a** of the second portion close to the negative tab **2321**, and the other end of the negative current collector **23222b** of the second portion is flush with the other end of the negative active material layer **23222a** of the second portion. The negative electrode plate **232** not only facilitates coating of the negative active material layer, but also may form the negative electrode plate **232** with a width difference between the third portion **23223** in the process of forming the negative tab **2321** through the die cutting, that is, the negative electrode plate with the width difference between the third portion **23223** and the second portion **23222** may be formed by using the original forming process of the negative electrode plate **232**.

The third portion **23223** is provided with a combining face **23223d** connected to the second portion **23222**; and negative tabs **2321** are multiple in quantity, one negative tab **2321** of the multiple negative tabs **2321** protrudes out of the third portion **23223** in the winding axial direction B and is provided with a second side face **2321c** close to the second portion **23222**, and the second side face **2321c** and the combining face **23223d** are coplanar. The combining face **23223d** and one side face of the negative tab **2321** are coplanar, so that a situation that the combining face **23223d**

29

warps due to no binding and then punctures the separator film **233** during and after winding may be avoided.

The third portion **23223** passes through the straight area I at least one time. In some embodiments, as shown in FIGS. **28** and **30**, the third portion **23223** passes through the straight area I one time, the second positive winding end portion **23123** passes through the straight area I one time, and a negative active material layer on an inner side of the negative current collector **23223e** of the third portion faces a positive active material layer on an outer side of a positive current collector **23123b** of the second positive winding end portion, so that only the negative active material layer on the inner side of the negative current collector **23223e** of the third portion may be widened so as to meet $H4-L3>H2-L2$.

In some embodiments, if an outer diameter of the winding needle for forming the electrode assembly **23** through winding is small, the number of times of passing through the straight area I by the third portion may be appropriately increased.

In some embodiments, as shown in FIGS. **31** and **32**, the third portion **23223** passes through the straight area I two times, and negative active material layers on inner sides of parts of the negative current collector **23223e** of the third portion in the two straight areas I face a positive active material layer on an outer side of the positive current collector **23123b** of the second positive winding end portion, so that only the negative active material layers on the inner sides of the parts of the negative current collector **23223e** of the third portion in the two straight areas I may be widened so as to meet $H4-L3>H2-L2$.

In some embodiments, as shown in FIGS. **33** and **34**, in the winding direction A, the third portion **23223** passes through the straight area I three times, the second positive winding end portion **23123** passes through the straight area I three times, which is divided into a straight area for first time, a straight area for second time and a straight area for third time according to a passing sequence (first→later). Negative active material layers on inner and outer sides of a part of the negative current collector **23223e** of the third portion in the straight area for first time face a positive active material layer on an outer side of a part of the positive current collector **23123b** of the second positive winding end portion in the straight area for first time and a positive active material layer on an inner side of a part of the positive current collector **23123b** of the second positive winding end portion in the straight area for third time respectively, and negative active material layers on inner sides of parts of the negative current collector **23222b** of the second portion in the straight area for second time and the straight area for third time face positive active material layers on outer sides of parts of the positive current collector **23123b** of the second positive winding end portion in the straight area for second time and the straight area for third time, so that in the winding axial direction B, only the negative active material layers on the inner and outer sides of the part of the negative current collector **23223e** of the third portion in the straight area for first time and the negative active material layers on the inner sides of the parts of the negative current collector **23222b** of the second portion in the straight area for second time and the straight area for third time may be widened so as to meet $H4-L3>H2-L2$.

As shown in FIG. **35**, if the third portion **23223** passes through the straight area I three times, the second positive winding end portion **23123** passes through the straight area I two times, positive active material layers on inner and outer sides of a part of the positive current collector **23123b** of the second positive winding end portion in the straight

30

area for second time face a negative active material layer on an outer side of a part of the negative current collector **23223e** of the third portion in the straight area for first time and a negative active material layer on an inner side of a part of the negative current collector **23223e** of the third portion in the straight area for third time respectively, and a positive active material layer on an outer side of a part of the positive current collector **23123b** of the second positive winding end portion in the straight area for first time faces a negative active material layer on an inner side of a part of the negative current collector **23223e** of the third portion in the straight area for second time. In the winding axial direction B, only the negative active material layer on the outer side of the part of the negative current collector **23223e** of the third portion in the straight area for first time and negative active material layers on inner sides of parts of the negative current collector **23223e** of the third portion in the straight area for second time and the straight area for third time may be widened so as to meet $H4-L3>H2-L2$.

In order to guarantee that the negative electrode plate **232** is capable of completely covering the positive electrode plate **231** in the winding direction A, the negative body **2322** further includes a second extending portion **23225**. In the winding direction A, the second extending portion **23225** is connected to one end of the third portion **23223** away from the second portion **23222**, and the second extending portion **23225** exceeds the tail end of the second positive winding end portion **23123** in the winding direction A. The second extending portion **23225** may be widened or not widened compared with the second portion **23222**. In FIG. **33**, the second extending portion **23225** is widened compared with the second portion **23222**, and in FIG. **36**, a negative active material layer of the second extending portion **23225** is not widened compared with the negative active material layer **23222a** of the second portion.

In some embodiments, the third portion **23223** may also be wound a circle. For example, when the winding type electrode assembly **23** is of a cylindrical structure, the third portion **23223** is wound at least one circle.

In some embodiments, a structure of the positive electrode plate **231** is improved so as to enable the maximum width difference between the positive active material layer **23121a** of the first positive winding end portion and the negative active material layer **23221a** of the first portion to be larger than the maximum width difference between the negative active material layer **23222a** of the second portion and the positive active material layer **23122a** of the positive winding middle section.

In some embodiments, as shown in FIG. **37**, in the winding axial direction B (consistent with the shown width direction C), a maximum width of the positive active material layer **23121a** of the first positive winding end portion is $L4$, a maximum width of the positive active material layer **23122a** of the positive winding middle section is $L5$, and $L4<L5$, so that a maximum width difference between the first positive winding end portion **23121** and the first portion **23221** is larger than a maximum width difference between the negative active material layer **23222a** of the second portion and the positive active material layer **23122a** of the positive winding middle section, and by changing a width of the first positive winding end portion **23121** of the positive electrode plate **231**, the risk that the size of the part, exceeding the positive active material layer of the positive electrode plate **231** in the winding axial direction B, of the negative active material layer of the negative electrode plate **232** does not meet the design requirement due to the relative

31

deviation between the positive electrode plate **231** and the negative electrode plate **232** is reduced.

In some embodiments, with further reference to FIG. **37**, a maximum width of the positive active material layer **23123a** of the second positive winding end portion is L_6 , the maximum width of the positive active material layer **23122a** of the positive winding middle section is L_5 , and $L_6 < L_5$, so that a maximum width difference between the positive active material layer **23121a** of the first positive winding end portion and the negative active material layer **23221a** of the first portion is larger than a maximum width difference between the negative active material layer **23222a** of the second portion and the positive active material layer **23122a** of the positive winding middle section, a maximum width difference between the positive active material layer **23123a** of the second positive winding end portion and the negative active material layer **23223a** of the third portion is larger than a maximum width difference between the negative active material layer **23222a** of the second portion and the positive active material layer **23122a** of the positive winding middle section, and the risk that the size of the part, exceeding the positive active material layer of the positive electrode plate **231** in the winding axial direction B, of the negative active material layer of the negative electrode plate **232** does not meet the design requirement due to the relative deviation between the head and the tail of the negative electrode plate **232** during winding is reduced.

The maximum width difference between the positive active material layer **23123a** of the second positive winding end portion and the negative active material layer **23223a** of the third portion is $H_4 - L_3$.

In some embodiments, the positive active material layer **23121a** of the first positive winding end portion may be of an equal-width structure, and $L_1 = L_4$. Or, the positive active material layer **23121a** of the first positive winding end portion may be of a variable-width structure, and $L_1 < L_4$.

In some embodiments, the positive active material layer **23122a** of the positive winding middle section may be of an equal-width structure, and $L_2 = L_5$. Or, the positive active material layer **23122a** of the positive winding middle section may be of a variable-width structure, and $L_2 < L_5$.

In some embodiments, the positive active material layer **23123a** of the second positive winding end portion may be of an equal-width structure, and $L_6 = L_3$. Or, the positive active material layer **23123a** of the second positive winding end portion may be of a variable-width structure, and $L_3 < L_6$.

In some embodiments, in the winding axial direction B, one end of the positive active material layer **23122a** of the positive winding middle section at least partially exceeds the corresponding end of the positive active material layer **23121a** of the first positive winding end portion, and the other end of the positive active material layer **23122a** of the positive winding middle section is flush with the other end of the positive active material layer **23121a** of the first positive winding end portion. In this way, the width of the first positive winding end portion **23121** is reduced from one side in the winding axial direction B relative to the positive winding middle section **23122**, so that a forming mode of the positive electrode plate **231** is simple and processing difficulty is reduced.

In some embodiments, in the winding axial direction B, the positive tab **2311** is located at one end of the positive electrode plate **231**, and one end of the positive active material layer **23122a** of the positive winding middle section close to the positive tab **2311** exceeds the corresponding end of the positive active material layer **23121a** of the first

32

positive winding end portion. One end of the positive active material layer **23122a** of the positive winding middle section close to the positive tab **2311** exceeds the corresponding end of the positive active material layer **23123a** of the second positive winding end portion. In this way, in a process of forming the positive tab **2311** through the die cutting or in a process of arranging an insulating layer **23124**, the positive electrode plate **231** with a width difference between the positive active material layer **23121a** of the first positive winding end portion as well as the positive active material layer **23123a** of the second positive winding end portion and the positive active material layer **23122a** of the positive winding middle section may be formed, thus reducing the processing difficulty.

Generally, the positive electrode plate **231** further includes the insulating layer **23124**, and the insulating layer **23124** is configured to separate burrs at one end of the positive body **2312** in the winding axial direction B from the negative body **2322** (shown in FIG. **18**) to reduce the short circuit risk. In the winding axial direction B, the insulating layer **23124** is arranged between the positive tab **2311** and the positive active material layer on the positive body **2312**, and the insulating layer **23124** is coated in the positive current collector of the positive body **2312**, so that the larger a width occupied by the insulating layer **23124**, the smaller a width of the positive active material layer with a corresponding position capable of being subjected to coating, otherwise, the smaller the width occupied by the insulating layer **23124**, the larger the width of the positive active material layer with the corresponding position capable of being subjected to coating. Therefore, a minimum width of an insulating layer **23124a** of the first positive winding end portion is larger than a maximum width of an insulating layer **23124b** of the positive winding middle section. A minimum width of an insulating layer **23124c** of the second positive winding end portion is larger than the maximum width of the insulating layer **23124b** of the positive winding middle section.

The insulating layer **23124** includes an inorganic filler and an adhesive. The inorganic filler includes one or more of boehmite, alumina, magnesia, titania, zirconia, silica, silicon carbide, boron carbide, calcium carbonate, aluminum silicate, calcium silicate, potassium titanate and barium sulfate. The adhesive includes one or more of polyvinylidene fluoride, polyacrylonitrile, polyacrylic acid, polyacrylate, polyacrylic acid-acrylate, polyacrylonitrile-acrylic acid and polyacrylonitrile-acrylate.

In some embodiments, in the winding axial direction B, the widths of the first positive winding end portion **23121**, the positive winding middle section **23122** and the positive active material layer **23123a** of the second positive winding end portion are consistent, the insulating layer **23124** is coated in one sides of the first positive winding end portion **23121** close to the positive tab **2311**, the positive winding middle section **23122** and the positive active material layer **23123a** of the second positive winding end portion, and the insulating layer **23124** is applied to the positive active material layer, so that the insulating layer **23124** overlaps with the positive active material layer, and the positive active material layer not covered by the insulating layer **23124** is an effective active material layer of the positive body **2312**. The maximum widths of the insulating layer **23124a** of the first positive winding end portion and the insulating layer **23124c** of the second positive winding end portion are both larger than the maximum width of the insulating layer **23124b** of the positive winding middle section, so that maximum widths of an effective active

33

material layer of the first positive winding end portion **23121** and an effective active material layer of the second positive winding end portion **23123** are both smaller than a maximum width of an effective positive active material layer of the positive winding middle section **23122**.

In some embodiments, as shown in FIG. **38**, in the winding axial direction B (consistent with the width direction C), it may also be one end of the positive active material layer **23122a** of the positive winding middle section away from the positive tab **2311** that exceeds a corresponding end of the positive active material layer **23121a** of the first positive winding end portion. One end of the positive active material layer **23122a** of the positive winding middle section away from the positive tab **2311** exceeds the corresponding end of the positive active material layer **23123a** of the second positive winding end portion.

In some embodiments, as shown in FIG. **39**, in the winding axial direction B (consistent with the width direction C), it may also be two ends of the positive active material layer **23122a** of the positive winding middle section that exceed two ends of the positive active material layer **23121a** of the first positive winding end portion correspondingly. The two ends of the positive active material layer **23122a** of the positive winding middle section exceeds the two end of the positive active material layer **23123a** of the second positive winding end portion correspondingly.

In some embodiments, the structures of the positive electrode plate **231** and the negative electrode plate **232** are improved to meet $H1-L1>H2-L2$ and $H4-L3>H2-L2$. Under the condition that part or all of the width of the negative active material layer **23221a** of the first portion is partially or completely increased, part or all of the width of the positive active material layer **23121a** of the first positive winding end portion is decreased. Under the condition that part or all of the width of the negative active material layer **23223a** of the third portion is increased, the part or all of width of the positive active material layer **23123a** of the second positive winding end portion is decreased.

In some embodiments, the negative active material layer **23223a** of the third portion is not widened compared with the negative active material layer **23222a** of the second portion, and by increasing a size of the negative active material layer **23221a** of the first portion in the winding axial direction B and decreasing a size of the positive active material layer **23123a** of the second positive winding end portion in the winding axial direction B, $H1-L1>H2-L2$ and $H4-L3>H2-L2$ are met.

In some embodiments, the negative active material layer **23221a** of the first portion is not widened compared with the negative active material layer **23222a** of the second portion, and by decreasing a size of the positive active material layer **23121a** of the first positive winding end portion in the winding axial direction B and increasing a size of the negative active material layer **23223a** of the third portion in the winding axial direction B, $H1-L1>H2-L2$ and $H4-L3>H2-L2$ are met.

The embodiments of the present application further provide the method for manufacturing a winding type electrode assembly **23**, and as shown in FIG. **40**, the method for manufacturing a winding type electrode assembly **23** includes that

S100: providing a positive electrode plate **231**, the positive electrode plate **231** including a first positive winding end portion **23121** and a positive winding middle section **23122** connected to each other;

34

S200: providing a negative electrode plate **232**, the negative electrode plate **232** including a first portion **23221** and a second portion **23222** connected to each other; and

S300: winding the positive electrode plate **231** and the negative electrode plate **232** to form the winding type electrode assembly **23**, so that the first portion **23221** is arranged opposite to the first positive winding end portion **23121**, and the second portion **23222** is arranged opposite to the positive winding middle section **23122**; and in a winding axial direction B of the winding type electrode assembly **23**, a negative active material layer of the negative electrode plate **232** exceeds a positive active material layer of the positive electrode plate **231**, a maximum width of a negative active material layer **23221a** of the first portion is $H1$, a minimum width of a positive active material layer **23121a** of the first positive winding end portion is $L1$, a maximum width of a negative active material layer **23222a** of the second portion is $H2$, a minimum width of a positive active material layer **23122a** of the positive winding middle section is $L2$, and $H1-L1>H2-L2$.

In the present application, an execution sequence of all the steps of the method for manufacturing a winding type electrode assembly **23** is not limited, as long as the electrode assembly **23** is manufactured.

The embodiments of the present application provide the apparatus **400** for manufacturing a winding type electrode assembly. As shown in FIG. **41**, the apparatus **400** for manufacturing a winding type electrode assembly includes a first providing apparatus **410**, a second providing apparatus **420** and an assembling apparatus **430**, where the first providing apparatus **410** is configured to provide a positive electrode plate **231**, the positive electrode plate **231** including a first positive winding end portion **23121** and a positive winding middle section **23122** connected to each other; the second providing apparatus **420** is configured to provide a negative electrode plate **232**, the negative electrode plate **232** including a first portion **23221** and a second portion **23222** connected to each other; and the assembling apparatus **430** is configured to wind the positive electrode plate **231** and the negative electrode plate **232**, so as to enable the first portion **23221** to be arranged opposite to the first positive winding end portion **23121**, and enable the second portion **23222** to be arranged opposite to the positive winding middle section **23122**, in a winding axial direction B of the winding type electrode assembly **23**, a negative active material layer of the negative electrode plate **232** exceeds a positive active material layer of the positive electrode plate **231**, a maximum width of a negative active material layer **23221a** of the first portion is $H1$, a minimum width of a positive active material layer **23121a** of the first positive winding end portion is $L1$, a maximum width of a negative active material layer **23222a** of the second portion is $H2$, a minimum width of a positive active material layer **23122a** of the positive winding middle section is $L2$, and $H1-L1>H2-L2$.

The positive electrode plate **231** and the negative electrode plate **232** provided by the first providing apparatus **410** and the second providing apparatus **420** may overcome a defect that the part, exceeding the positive active material layer of the positive electrode plate **231**, of the negative active material layer of the negative electrode plate **232** is not enough due to the relative deviation of the positive electrode plate **231** and the negative electrode plate **232** at the head or tail caused by a structural tolerance and a

35

winding error of the assembling apparatus 430 in a process of forming the winding type electrode assembly 23 through winding.

Although the present application has been described with reference to preferred embodiments, various modifications may be made and equivalents may be substituted for parts thereof without departing from the scope of the present application. Especially, as long as there is no structural conflict, the technical features mentioned in the embodiments may be combined in any way. The present application is not limited to the specific embodiments disclosed herein, but includes all technical solutions falling within the scope of the claims.

What is claimed is:

1. A winding type electrode assembly, comprising:

a positive electrode plate comprising a first positive winding end portion and a positive winding middle section connected to each other; and

a negative electrode plate comprising a first portion and a second portion connected to each other, wherein the first portion is arranged opposite to the first positive winding end portion, and the second portion is arranged opposite to the positive winding middle section; and

in a winding axial direction of the winding type electrode assembly, a negative active material layer of the negative electrode plate exceeds a positive active material layer of the positive electrode plate, a maximum width of a negative active material layer of the first portion is H1, a minimum width of a positive active material layer of the first positive winding end portion is L1, a maximum width of a negative active material layer of the second portion is H2, a minimum width of a positive active material layer of the positive winding middle section is L2, and $H1-L1>H2-L2$.

2. The winding type electrode assembly according to claim 1, wherein a minimum width of the negative active material layer of the first portion is H3, wherein $H1>H2$, and $H3>H2$.

3. The winding type electrode assembly according to claim 2, wherein in the winding axial direction, at least part of one end of the negative active material layer of the first portion exceeds a corresponding end of the negative active material layer of the second portion, and the other end of the negative active material layer of the first portion is flush with the other end of the negative active material layer of the second portion.

4. The winding type electrode assembly according to claim 3, wherein the negative electrode plate further comprises a negative tab, in the winding axial direction, the negative tab is located at one end of the negative electrode plate, and one end of the negative active material layer of the first portion close to the negative tab at least partially exceeds a corresponding end of the negative active material layer of the second portion.

5. The winding type electrode assembly according to claim 1, wherein $0.3\text{ mm}\leq H1-H2\leq 3\text{ mm}$.

6. The winding type electrode assembly according to claim 1, wherein the negative electrode plate further comprises a negative tab, in the winding axial direction, the negative tab is located at one end of the negative electrode plate, one end of the first portion close to the negative tab exceeds a corresponding end of the second portion, and the other end of the first portion is flush with the other end of the second portion.

7. The winding type electrode assembly according to claim 6, wherein in a winding direction of the winding type

36

electrode assembly, the first portion is provided with a connection surface connected to the second portion; and

negative tabs are multiple in quantity, one of the multiple negative tabs protrudes out of the first portion in the winding axial direction and is provided with a first side face close to the second portion, and the first side face and the connection surface are coplanar.

8. The winding type electrode assembly according to claim 6, wherein in the winding axial direction, the negative tab protruding out of the first portion is provided with a negative active material layer, and the negative active material layer on the negative tab protruding out of the first portion is connected to the negative active material layer of the first portion.

9. The winding type electrode assembly according to claim 1, wherein the winding type electrode assembly comprises a straight area and two bent areas, and the two bent areas are connected to two ends of the straight area respectively; and

the first portion passes through the straight area at least two times.

10. The winding type electrode assembly according to claim 1, wherein the positive electrode plate further comprises a second positive winding end portion, and first positive winding end portion and the second positive winding end portion are connected to two ends of the positive winding middle section respectively;

the negative electrode plate further comprises a third portion, the first portion and the third portion are connected to two ends of the second portion respectively, and the third portion is arranged opposite to the second positive winding end portion; and

a maximum width of a negative active material layer of the third portion is H4, a minimum width of a positive active material layer of the second positive winding end portion is L3, and $H4-L3>H2-L2$.

11. The winding type electrode assembly according to claim 10, wherein a minimum width of the negative active material layer of the third portion is H5, wherein $H4>H2$, $H5\geq H2$.

12. The winding type electrode assembly according to claim 1, wherein a maximum width of the positive active material layer of the first positive winding end portion is L4, a maximum width of the positive active material layer of the positive winding middle section is L5, and $L4<L5$.

13. The winding type electrode assembly according to claim 12, wherein in the winding axial direction, one end of the positive active material layer of the positive winding middle section at least partially exceeds a corresponding end of the positive active material layer of the first positive winding end portion, and the other end of the positive active material layer of the positive winding middle section is flush with the other end of the positive active material layer of the first positive winding end portion.

14. The winding type electrode assembly according to claim 13, wherein the positive electrode plate further comprises a positive tab, in the winding axial direction, the positive tab is located at one end of the positive electrode plate, and one end of the positive active material layer of the positive winding middle section close to the positive tab at least partially exceeds a corresponding end of the positive active material layer of the first positive winding end portion.

15. A battery cell, comprising the winding type electrode assembly according to claim 1.

16. A battery, comprising the battery cell according to claim 15.

37

17. A power consumption device, comprising the battery cell according to claim 15.

18. A method for manufacturing a winding type electrode assembly, the method comprising:

providing a positive electrode plate, the positive electrode plate comprising:

a first positive winding end portion and a positive winding middle section connected to each other;

providing a negative electrode plate, the negative electrode plate comprising:

a first portion and a second portion connected to each other; and

winding the positive electrode plate and the negative electrode plate to form the winding type electrode assembly, so as to enable the first portion to be arranged opposite to the first positive winding end portion, and enable the second portion to be arranged opposite to the positive winding middle section,

wherein in a winding axial direction of the winding type electrode assembly, a negative active material layer of the negative electrode plate exceeds a positive active material layer of the positive electrode plate, a maximum width of a negative active material layer of the first portion is H1, a minimum width of a positive active material layer of the first positive winding end portion is L1, a maximum width of a negative active material layer of the second portion is H2, a minimum width of a positive active material layer of the positive winding middle section is L2, and $H1-L1>H2-L2$.

38

19. A device for manufacturing a winding type electrode assembly, the apparatus comprising:

a first providing apparatus configured to provide a positive electrode plate, the positive electrode plate comprising a first positive winding end portion and a positive winding middle section connected to each other;

a second providing apparatus configured to provide a negative electrode plate, the negative electrode plate comprising a first portion and a second portion connected to each other; and

an assembling apparatus configured to wind the positive electrode plate and the negative electrode plate, so as to enable the first portion to be arranged opposite to the first positive winding end portion, and enable the second portion to be arranged opposite to the positive winding middle section,

wherein in a winding axial direction of the winding type electrode assembly, a negative active material layer of the negative electrode plate exceeds a positive active material layer of the positive electrode plate, a maximum width of a negative active material layer of the first portion is H1, a minimum width of a positive active material layer of the first positive winding end portion is L1, a maximum width of a negative active material layer of the second portion is H2, a minimum width of a positive active material layer of the positive winding middle section is L2, and $H1-L1>H2-L2$.
